In St. BEER words: "The Homeostat is precisely a machine for settling down again after it has been disturbed" (1967, p.117). As such a property is very general in **complex systems** which must "cope with an unpredictable **environment**..." (conveying) **random information**" (p.118), the homeostat can be considered a **behavioral modelling** device of considerable interest. In effect, "we are returned to the old issue of **machine design**, and that of **adaptive behavior** to **situations** not envisaged by the designer" (Ibid).

ASHBY gives a complete description of this "**machine**", whose main points are that: "The homeostat consists of four units, each of which carries on top a pivoted magnet. The angular deviations of the four magnets from the central positions provide the four main **variables**" (1960, p.100)...

Each unit may take 25 different positions and its **outputs** are transmitted in a randomized way to the other units and influence their **activity**, thus providing 25⁴, i.e. 390.625 combinations of **parameter-values**.

ASHBY explains that: "The **field** of the four main **variables** has only one **state of equilibrium** (at the centre), which may be stable or unstable. Thus the system is either stable and self-correcting for small impulsive displacements to the needles, or unstable and self-ag-

gravating, running away to the **limits** of the throughs. Which it will be depends on the quantitative details of the primary **feedbacks**, which are dependent on the values on the **step-mechanisms**" (p.104).

As stated by E.von GLASERSFELD, ASHBY's device would gradually **learn** to "... make appropriate **connections** by **learning** on the basis of its own experience which **activities** help to reduce which **error-signals**" (1988, p.117).

However, as stated by St. BEER: "... if a homeostat in an equilibrial **state** is bombarded without respite by **wave** after **wave** of **input data**, it will go into an **oscillation** from which it can never recover... if the **periodicity** of the **input** is very much faster than the **cycle time** of the homeostat itself, then clearly it has no opportunity to settle" (1968, p.384).

Thus, either the **periodicity** of the **input** must be extended or, if it can be proved repetitive, an adaptive **algorithm** must be evolved.

Numerous **behaviors** of many kinds of systems can be mimicked on this not too complicated device, as for example the tendency to **stability** or **instability**, the ways of **training**, some failures of **adaptation**, etc...

The homeostat, which is now somewhat forgotten, could still probably be very useful.

On the semantic convenience of the name "Homeostat", ASHBY wrote: "It was given the name of "Homeostat" for convenience of reference, and the noun seems to be acceptable. The derivatives "homeostatic" and "homeostatically", however, are unfortunate, for they suggest reference to the **machine**, whereas priority demands that they be used only as derivatives of CANNON's "**Homeostasis**" (1960, p.100).

1578

HOMOGENEITY¹⁾

Quality of a group of **elements** which are all of the same nature and endowed of a similar behavior.

No **concrete system** can be totally homogeneous. Only the abstract "**isolated system**" after its full entropization could reach total homogeneity.

As the state of maximum homogeneity corresponds to the maximum **level** of **entropy**, and a total **independence** of the **elements**, a maximum of **information** should be required to obtain a full **knowledge** of the **state** of the **set** of all the **elements** at some moment. This is the basic reason why an inverse relation between **information** and **entropy** could be stated and established by various authors, as Cl. SHANNON and L. BRILLOUIN.

In **concrete systems**, the 2nd. law of **thermodynamics** is always finally prevalent, leading to homogeneity in the system... and its final demise and **dispersal**, i.e. its reduction to uncoordinated **elements**.

This final **state** of entropization is an **attractor** for the system.

However, in complex systems, local **states** of relative homogeneity may exist in **subsystems**, reflecting **dynamically stable functions**. St. KAUFFMAN propose to call these states "internal homogeneity **clusters**" (1993, p.203).

1579

HOMOLOGY²⁾ - 5)

The correspondance of **elements** or **subsystems** within different systems.

This concept is translated from mathematics to systemics. It can be used to track possible functional or structural partial **isomorphies**, but this should be done carefully, because homologies can be more apparent than real.

Their use was however proposed by L.von BERTALANFFY.

1580

HOMOMORPH²⁾

A **model** that differs from another only with respect to detail. (after G. PASK, 1961, p.32)

G. PASK states, curiously: "Now, the second homomorphic **model**, is also the **observer's** eye view of an **observer** who had thrown away some of the available **information** (in a carefully calculated manner, so that his **image** is less detailed than but consistent with the original)" (Ibid).

The construction of homomorphs is an **observer's** business. Moreover, homomorphs should never be mistaken for **isomorphs**, a quite rarer type of **models**.

1581

HOMOMORPHISM²⁾

A many-to-one **mapping** of some characteristics of a **concrete system** onto a **model** of the same.

An homomorphism is an imperfect, partial or limited **isomorphism**. K. KRIPPENDORFF writes: "Homomorphisms are important in establishing whether one system is a **model** of another and which properties of the original of the system the **model** retains. For each system one can **construct** a **lattice** of homomorphic simplifications" (1986, p.36).

G. KLIR explains: "An homomorphic relation between two systems is contingent upon a **function** from relevant entities of one system (the original) onto the corresponding entities of the other system (the **modelling** system) under which the relation among entities is preserved. If the **function**, which is called a homomorphic **function**, is **bijective**, the relation is preserved completely (we say that the two systems are **isomorphic**); otherwise it is preserved only in a simplified form" (1993, p.30).

The last case is by far the most common.

R. VALLÉE, refering himself to the example of "the **map**, which is not the territory" (KORZYBSKI) states: "The **map** is not supposed to provide useless details. Homomorphism is enough, and the degree of accuracy of a **representation** ought to be adapted to the purpose for which it has been chosen: **cognition**, action or any other end" (1991, p.4).

V. TURCHIN makes the suggestive comment – helpful in placing **models** in proper perspective – that: "A **model** is a family of homomorphisms" (1993, p.7).

1582

HOMOPLATY²⁾

The condition of a **region** of **space** that is about as broad and as long as possible.

This notion was introduced by L.F. RICHARDSON.

"The geometric figure which satisfies completely the property of 'homoplasy' is the circle. It is known, however, that a two-dimensional region cannot be divided into contiguous circles" (1961, p.139).

In such a space, the closest approach to homoplasy is obtained by hexagonal **clusters**. See: (two dimensional) "**space structuration**". This has very important implications for **space** occupancy in general ("**hexagonal space filling**").

1583

HOMOTOPY²⁾

Property of two **paths** in a **topological space** that can be deduced from each other by continuous deformation.

The main interest of this concept is to allow for comparisons between **forms** which could seem at first sight unrelated.

Homotopic deformation has been extensively used by d'Arcy W. THOMPSON in his famous work "On **growth** and **form**" (1916, 1952). THOMPSON applied it to comparative anatomy and phylotaxy, but also to the mechanical **structures** in bridges and other constructions and, generally, to the study of the relations between **forms**.

Homotopy is a special case of **homeomorphism** and **isomorphisms**

1584

HORA and TEMPUS parable¹⁾

A parable about two watchmakers, by H. SIMON showing the conditions for the **evolution** of **complex systems**, demonstrating that "... a system composed of independent stable **subsystems** can withstand **perturbations** to a significantly higher degree than systems build directly from their **components**" (1974, p.223).

In short, interconnecting pre-ordained **subsystems** is a more efficient way to construct a complex **entity**, rather than to do it from a mere mass of unrelated **elements**.

→ **Evolution of complex systems; Modularity (Weak); Module**

1585

HUB¹⁾²⁾

A **node** in a **network** linked with many other **nodes**.

Hubs are important because they ease long distance **communication** in the **network** by reducing the number of intermediate steps needed to connect any **node** with any other one.

(see "**small world**") Each hub becomes a concentration and distributive center for **information** in the **network** and contributes to its structuration. Hubs are a basic feature, specially in Internet to which they provide innumerable short cuts, simplifying and accelerating **communication**. Thus, hubs are not merely static **elements**, but are also basic in **dynamics**.

Hubs can be found in many different classes of networks. D. COHEN for ex., writes: "Food webs – the networks of who eats whom in various **ecosystems** – are built around "hub species" that eat large number of different prey species..." (D. COHEN, 2002). Hubs are also basic in human societies: A scientific journal, for instance, can be considered a hub for the world diffusion of specific **information**, among widely separated **groups** working on related subjects.

Also, in the propagation of **epidemics**, some individuals, in particular promiscuous ones in the case of AIDS, may be viewed as hubs, who can easily created new foci in very distant places. Cohen even writes: "... the way HIV spreads through **populations** is similar to the spread of viruses on the Net". Hubs are also important in **graphs** used in social psychology to describe interpersonal **relationships** within and among **groups**. In short, hubs are all-important in terms of multiple social **interconnections** of any kind.

As a basic organization feature, hubs are also somehow related to ASHBY's **constraints**.

The number of hubs in a **network** is related to the number of **nodes** by a **power law**: there are much less hubs than common **nodes** and the most connected hubs are also the less frequent ones (See D. WATTS, 1999).

An unfortunate feature of highly connected hubs is that their accidental or wilful destruction, sometimes at one stroke, can impair or even destroy the whole network. Examples are widespread blackouts in interconnected electrical grids, or extensive functional impairment as a result of a cerebral haemorrhage

The notion of Hub has been considered in its most general sense by A.L. BARABASI (2002).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

The word "**neurode**" is used in a quite closely related meaning.

1586

HUMAN ACTION SYSTEM ⁴⁾

A general model for human activities.

The general idea of such a **model** is proposed by R. RODRIGUEZ DELGADO who writes that it "would be necessary in each case to conceive a Human Action System, its **interrelationships**, its adequacy to different **environments**, and the possibilities of applying the generalized **principle of complementarity** to problems that at first view appear as antagonistic or conflictive" (1990, p.7).

1587

HUMAN ACTIVITY SYSTEM ⁴⁾

P. CHECKLAND introduces this **concept** in the following way: "The system "man" is crucial because of man's ability, as tool maker, myth maker and doer, to change his **environment** and his circumstances within it. Given man and his abilities, we have the huge area of "human activity systems", from the one-man-with-a-hammer... to the international political systems which we shall have to forge if life is to remain tolerable for the human race on this finite planet...

"Human activity systems must be designated in two different ways. Firstly there are the physical collections of **components** which are the structural **set** which makes the system; and secondly, because of the nature of the human **component**, there are the activity systems which are concerned with processing **information**, making plans, carrying out operations, monitoring **performance**, taking **control action**, taking leisure, finding things out, and so on" (1972, p.52).

B. BANATHY introduced a still wider embracing **concept** of "Human activity system" in 1987. He described it as follows: "Human activity systems, such as **organizations** and social systems, can give direction to their **evolution** and shape their future by engaging in **design** inquiry. They can enhance their continuous **development** and improve their effectiveness by purposeful **design**". He understands design as "creative, decision-oriented, disciplined inquiry that first clarifies the reason for engaging in **design**: then diagnoses and describes the **design problem situation**; formulates expectations, **purpose** and requirements of the system to be designed or redesigned; generates and clarifies alternative **representations** of the system that can meet those requirements and expectations; devises **criteria** by which to evaluate those alternatives; and prepares a plan for the **development** and im-

Figure: see entry **HYPERCUBE ARCHITECTURE**

The Hypercube as a 4-dimensional connection model
From S. KAUFFMAN: 1993, p. 38

plementation of the selected **design**" (1987, p.54).

These **concepts** and proposals are developed by the **FUSCHL Group**, whose endeavor is to translate them to the **transformation** of real systems.

The general methodology (**co-participative design**) is close to J. WARFIELD's **Generic Design**.

- Three factors seem of particular importance:
- A careful study of the **situation** as it is and of the causes that led to it (in order to avoid any problem of **underconceptualization**).
 - The avoidance of ideological illusions, which very easily creep in idealistic groups unaware of their own biases.
 - The necessity to promote the effective participation of all the members of the group interested in the **design** and its results.

K. BAUSCH, in turn gives the following definition: "A **designed** social system organized for a **purpose**, which they attain by carrying out specific **functions**" (K. BAUSCH, Glossary, pers. comm., 2002)

Of course, the relation between the purpose (or purposes) of the social system and its design is crucial. In particular, there is wide difference between a system designed by an individual (the "boss" or "bosses") for own purpose and another system designed by a **conversation** group of would be **stakeholders**.

For now and for any practical purposes, this is the first type of human activity systems completely predominates (with only the peculiar case of religious **groups** or charities)

1588

HUMAN SYSTEMS (Rule-bound)

→ Rule-bound human systems

1589

HYDROSPHERE ¹⁾²⁾

The portion of the earth's crust covered by water

It includes not only the oceans, but also the lakes and rivers and in a sense the polar ices and the aquifers

→ **Atmosphere; Biosphere; Ekistics; Lithosphere; Sociosphere; World-engine**

1590

HYPERCUBE ARCHITECTURE ²⁾

A way to organize complex **interconnections** between **elements** in a multi-dimensional **space**.

... or, in a more formal fashion: A **structure** of **interconnections** among **elements**, selected by chosen **constraints** applied to the **set** of all possible **interconnections** among the vertices of a n-dimensional hypercube.

In a 4-dimensional Boolean hypercube, for example, a possible **constraint** is to admit direct **connexions** of any vertex with only its four direct neighbors. In this case, the **communication** with any other vertex demands at most four steps (through at most three intermediate **vertices**).

The hypercube architecture is a basic **model** for massively **parallel processes** between very numerous and interconnected **elements**.

D. HILLIS original **connection machine** is constructed around an **interconnection network** based on a 12 dimensions hypercube geometry allowing the **interconnection** of 4096 **nodes**.

see figure previous page 287

1591

HYPERCYCLE^{1) - 2)}

A self-reproductive **catalytic reaction cycle** made of sequentially interconnected **replicative sub-cycles**.

In M. EIGEN and P. SCHUSTER words: "A catalytic hypercycle is a system which connects **autocatalytic** or self-replicative units through a **cyclic linkage**". More precisely: "... it consists of self-instructive units I_i with two-fold **catalytic functions**. As **autocatalysts** – or more generally – as **catalytic cycles** the intermediate I_i are able to instruct their own **reproduction** and, in addition, provide **catalytic support** for the **reproduction** of the subsequent intermediate" (1979, p.5).

And, in more general terms: "The hypercycle is the tool for integrating length-restricted self-replication entities into a new stable **order**, which is able to evolve coherently. No other kind of **organization**, such as mere **compartmentation**, or **non-cyclic networks** could fulfill simultaneously all three of the following conditions:

- to maintain **competition** among the wild-type **distribution** of every **self-replicative entity** in order to preserve their **information**;
- to allow for a coexistence of several (otherwise competitive) **entities** and their mutant **distribution**, and
- to unify these **entities** into a coherently evolving unit, where advantages of one individual can be utilized by all members and where this unit as a **whole** remains in sharp **competition** with any unit of alternative composition" (p.VII).

In St. KAUFFMAN's word: "... the mutually cyclic **connections** among **template** pairs, which are themselves already **autocatalytic**, constitute a higher **order** hypercycle, coupling such **autocatalytic** units" (1993, p.359). While elemental units are subject to possible errors, "the hypercycle as a whole is not" (Ibid).

This suggests an explanation to von NEUMANN's **reliable networks** out of **unreliable components**.

The hypercycle could be defined as an "**eigen-transitions**" process, in von FOERSTER's style, linking the hypercycle with **autopoiesis**. It also seems to correspond to H. HAKEN's **order parameter**. The whole process can be represented through the following graph

As observed by E. LASZLO: "The **loop** may involve a large number of **elements**, but it ultimately closes in upon itself, forming a remarkably fast and stable reaction **cycle**" (1992, p.243).

The Hypercycle.

From M. EIGEN and P. SCHUSTER: 1979, p. 50

Hypercycles are a very general constructive and reproductive **organization model**. They obviously open the road to the build-up of **complexity** at successive evolutive levels.

The global **organization** of the hypercycle implies necessarily a **hierarchical order** reflecting an ordered **cooperation** among mutually replicating **elements**.

1592

HYPERHISTORY¹⁾

Arno Peters (1916-2002), a german historian, developed in 1952, the "synchronoptic" model of world history, whose main goal is to produce the "visualization of the concurrent" in history.

His model included 3000 facts related to all main human activities: science, culture, religion and politics.

This allowed probably for the first time a general synthetic and integrated view of mankind general evolution. It is an important tool to construct a systemic understanding of the whole subject.

Moreover, the model is useful to eliminate the biases that result from culturo-centrism.

1593

HYPERINPUT

→ Cellular Automation

1594

HYPERSPACE^{2) - 5)}

A **space** with more than three dimensions.

These abstract **spaces** can be used to represent the potential **interrelations** and **configurations** among numerous **elements**, but apart from the **hypercube**, they are practically impossible to visualize.

1595

HYPERSTATE

→ Cellular Automation

1596

HYPOSTATIZATION³⁾

"Reification of some **order** intrinsic to the mind" (J.W. SUTHERLAND, 1973, p.57).

It became clearer in the recent years that there is indeed some intrinsic **network organization** in the **brain** (let us be careful with the concept of *mind*).

SUTHERLAND explains in this way the origin of mathematics and consider that "... a similar claim for a priori ordering of some kind may be made with respect to CHOMSKY's postulation of immanent 'deep structures'".

Our access to reality is thus here again depending on the nature of the basic tool we must use to study it: our brain and our nervous system.

1597

HYPOTHESIS (Cross-level) method

See "Cross-level research in living systems"

1598

HYPOTHETICALITY¹⁾³⁾

The nature of "**situations** in which we have to make life-or-death **decisions** but are unable to perform the **experiments** or tests needed to gain much-needed **information** about the **situation** before having to make the **decision**". (J. CASTI, 1997, p.8 - after Wolf HAEFELE, former director of the German Nuclear Research Center in Juelich).

The **situations** alluded to are complex ones, in which an important number of elemental **processes** in **interaction** should be considered **simultaneously**. In such cases the **dynamics** of the situation generally becomes **chaotic** and **predictability** is possible only within the limits of a statistically reduced **determinism**.

In J. WARFIELD words, our problem in such cases is to "transform **complexity** into **understanding**" (1999, work in progress, pers. comm.)

→ Christmas tree effect

1599

HYSTERESIS^{1) - 2)}

The property of a system which does not return to its original **state** when submitted to a **variation**.

N. RASHEVSKY explains that hysteresis result of the fact: "... that the properties and **reactions** of a system are determined not merely by its present surroundings but also by the conditions of these surroundings at previous **times**, or, in other words, that those properties are determined by the past history of the system" (1960, p.69).

The classical example of hysteresis in physics is the failure of a magnetized body to return to its former level of magnetization when the value of the magnetic **field** is reduced.

However the phenomenon is very general. RA-SHEVSKY states: "From this point of view, various **phenomena** in the central nervous system, such as those connected with **learning**, **adaptation**, etc. are merely complex forms of hysteresis" (Ibid).

This connects the subject with **autopoiesis**.

R. ROSEN explains: "A system exhibiting hysteresis has the capacity to "remember", in a certain sense, that it was exposed to a **parameter variation**, in that the **behavior** of such a system will generally be different from that of an identical system which was not exposed to the **parameter variation**. Indeed, in biology hysteresis has often be used, implicitly or explicitly, as a **model** for **short-term** or **long-term memories**".

Of course, there are no "identical" systems, but this **semantic** lapse does not annulate ROSEN's argument.

He states, moreover, that it is often possible to "erase" the **memory** of such a **perturbation** "... provide we can reduce the **parameter P** sufficiently *below* the original value $P = P_0$; this gives rise to the well-known concept of the **hysteresis loop**. But it is by no means always possible" (1974, p.98).

I

1600

ICON³⁾

"A **sign** which would possess the character which renders it significant, even though its **object** had no existence" (C.S. PEIRCE, in J. HOOPES ed., 1991, p.239).

PEIRCE gives the following example: "... a lead-pencil streak as representing a geometrical line" (p.239).

Icons have, or acquire quickly, a symbolic character, which easily elicits a **variety** of possible reactions in people, even at the level of **conditioned behavior**.

Examples of icons are the red cross, the national flag, the Ying and Yang symbol, etc.

Some icons in history have been used with well defined **purpose** of political and psychological manipulation, as for example the svastika or the hammer and sickle.

The icon has always a diagrammatic character (p.181) and "partakes of some more or less overt character of its **object**" (p.252).

As such, PEIRCE considers that it somehow has the character of a fallacy, or a **metaphor**. This is important for systemics, in order never to forget that "the **map** is not the territory", or the **model** is not the entity it seeks to represent.

1601

IDEA¹⁾³⁾

"The smallest unit of mental process" (G. BATESON, 1979, P. 228)

This is in Bateson's view the "**difference** or distinction or news of a difference" (Ibid)

He adds: "What is called an idea in popular speech seems to be a complex **aggregate** of such units. But popular speech will hesitate to call, say, the bilateral **symmetry** of a frog or the **message** of a single neural impulse an idea (Ibid)

Truly, the "idea" of what an idea is appears to be quite **fuzzy**. The word in itself is in fact a **label** stuck on a still insufficient understanding of our **cerebral processes**.

1602

IDEAL TYPE

"An intellectual **construct** to aid thinking (Hence an **epistemological** concept)" (R. RODRIGUEZ ULLOA, Glossary, 1999)

An ideal type is thus "not a **description** of something in the real world... The word "ideal" is not **normative**, the function of ideal types being to enable comparisons to be made and theories to be developed... (even if) they are usually constructed from empirically observable or historically meaningful **components** - for example the individual **activities** in a **human activity system**" (Ibid).

In synthesis, "ideal" is about ideas, not about **ideology**.

1603

IDEALIZATION (Spurious)³⁾

"The reification of highly reduced concepts" (D. Mc NEIL, pers. comm.)

As examples of this type of mental trap, Mc NEIL lists: "... dimensionless points, perfect planes and straight lines and **linear** dependencies and independent **objects**" (Ibid). One of the main efforts of systemics is to try to create less reduced **models** of concrete **objects** and **situations**... and to become clearly conscious that they are still *models* of reality, only hopefully somewhat less artificial.

1604

IDEAL-SEEKING SYSTEM^{3) - 4)}

A system able to pursue **truth**, or ultimate good, or any other **value**.

This concept, as derived from the notion of **purposive system**, represents very well the idealistic current among systemists, i.e. basically E.A. SINGER Jr, C. W. CHURCHMAN, and their followers. Since the **meaning** given to "truth", or "good", or "beauty", or any other supposedly absolute **value**... can be very variable according to different proponents, the ideal-seeking system concept is necessarily somewhat controversial in the ways it is used.

Moreover, there are differences between those who believe that individuals *and* societies can be ideal-seeking (R.L. ACKOFF) and those who consider that only individuals can be (F.E. EMERY).

This last author, as quoted by G.A. BRITTON and H. McCALLION (1994, p.497 - principal source of this entry), "postulates the following characteristics of ideal-seeking systems:

"1) Only individuals can be ideal-seeking systems

"2) Individuals can sustain the ideal-seeking state only temporarily

"3) Ideal emerge only within **group** life.

"4) No ideal can be pursued single-mindedly without sacrifice of the others.

"5) The essence of wisdom is deciding on what sacrifice of other ideals should be made in any particular **choice** between **purposes**" (p.497).

Even this quite matter-of-facts statement cannot dispel doubts about what happens when encountered ideals (within the same ideal-seeker, or still more so, among various ones) are coming in opposition. Moreover, ideals are most frequently convenient fodder for **ideology**.

In any case, a good systemic **description** of the roots of ideal-seeking as a commonly observed **behavior** would still be very useful: how and why it appears, and how it operates in the mind of the ideal-seekers.

1605

IDEAL-TYPE^{2) - 3)}

"An **abstraction** which emphasizes certain properties which are felt to be distributed among real-world entities, and emphasizes them in such a way as to produce a highly directive and normative **model**" (J.W. SUTHERLAND, 1973, p.44).

According to SUTHERLAND, "The **model** is directive (if not operationally, at least experimentally) in that it provides the major premises from which some logical conclusions may be drawn" (Ibid).

The use of ideal-types is subagent to any **taxonomy**: "... an ideal-type is one **element** in an array of ideal-types which, as a **set**, constitutes a proper **taxonomy**". (Ibid., p.45).

One should always be careful not to confuse ideal-types for the **entities** they represent. For the way ideal-types are constructed, see KORYBSKI's **Structural differential** (1950).

Of course, in SUTHERLAND's words: "...**taxonomies** and ideal-types are themselves theories" (p.68).

SUTHERLAND distinguishes mechanical and organic ideal-types (p.97).

1606

IDEAL-TYPE (Mechanical)^{1) - 2)}

SUTHERLAND describes as follows the characteristics of the mechanical ideal-types:

"Interface conditions: Usually exist within well-defined, tangible **boundaries** which may be adjusted **endogenously** for greater or lesser **selectivity** with respect to entering or exciting forces.

"Structural characteristics: Generally has its **components** arrayed in a neat, observable **hierarchy**, such that properties at one **level** tend to be extrapolations of properties at other **levels**, with **relationships** among the various **levels** being essentially **deterministic**.

"Dynamic properties: **Parts** are usually highly **constrained**, having only a limited **repertoire** of **responses** permitted to them; causal **trajectories** and **paths** of **interaction** are generally fixed, controllable and exclusive; driving forces are generally tangible and measurable.

"Normative analytical properties: Potentially **total**:- **observability** – measurability – manipulability – **predictability**.

"Amenability to inference and induction: Given **initial state conditions**, future **states** may be induced with a high probability of accuracy" (1973, p.97).

1607

IDEAL-TYPE (Organic)^{1) – 2)}

According to SUTHERLAND, the characteristics of organic ideal-types are as follows:

"Interface conditions: Highly **open** with respect to **environment** and **exogenous** forces. External determinants which affect the system may, therefore, be too far removed (spatially or temporally) to be analytically observable at any point of **time**.

"Structural characteristics: **Parts** are not arrayed in a neat, stable **hierarchy** but **stochastically**, with the **structure** and direction of interrelationships generally altering almost constantly in response to localized **changes** of **environmental** influences, etc.

"Dynamic properties: **Parts** have potential for inaugurating opportunistic or strategic **behavior** in response to local **parameter changes**; causal **trajectories** may be altered locally and **interactions** may be **equifinal**; dynamic (driving) forces may be transparent rather than tangible and manipulable.

"Normative analytical properties: Only **partial**:

- empirical inaccessibility
- immeasurability
- imperfect controllability
- **unpredictability**

"Amenability to **inference** and **induction**: Future **state** conditions cannot be successfully inferred from **initial state** conditions" (p.97).

1608

IDENTIFICATION (Spurious)¹⁾

The abusive identification of any **model** with the **concrete system** it claims to represent.

As a matter of fact, rigorous identification seems to be always spurious, with the possible exception of completely abstract **isomorphisms** obtained from different sources.

As stated by A. KORZYBSKI, "the **map** is not the territory". No **model** can ever be complete, nor completely accurate. Moreover, **models** contain hidden assumptions and, in many cases, downright prejudices. Abusive identification may lead to erroneous and even dangerous conclusions about the real **situations**.

"Identification" is not given here the significance of "**recognizing the identity**" (see hereafter).

1609

IDENTITY¹⁾

The set of permanent characteristics of a system which allows to recognize it in different instances.

The establishment of identity is preceded by a **process** of **entification**.

The identity of a system is based on its **auto-poietic relations of production**, which leads K. KRIPPENDORFF to define it in a seemingly dubious way, as: "A **transformation** always reproducing the original" (1986, p.27).

Even in this sense, identity is thus merely the persistence in **time** of the basic characteristics of the entity (See hereafter).

Absolute identity between **two** or more **objects** is obviously impossible, as it would imply perfect coincidence of their spatial and temporal characteristics. Identity in this sense is possible only among **abstract** entities.

1610

IDENTITY TRANSFORM²⁾

"... The condition where the representative point of the system is trapped in a single **confluent**" (St. BEER, 1968, p.477).

BEER explains: "That is a lethal state of affairs; the system can no longer adapt: however much it is stimulated, and however often the point leaves **equilibrium** in E., it always returns. This is the **model** of over-specialization, of **obsolescence** leading to extinction and death" (Ibid.).

Systems reach this condition when the amount of **redundancy** contained in their original **program** becomes nearly exhausted. This is closely related to **ageing** and **equifinality**, and also to a dwindling **amplitude** of **homeostatic fluctuations**. All of these **effects** reflects the finally unavoidable increase of **entropy** in the system.

While BEER refers himself more specifically to human **organizations**, the **concept** may also be applied to biological systems.

1611

IDEOLOGY^{1) – 3) – 4)}

A body of statements tending to impose **values**, beliefs and **behavioral norms** in a **social system**.

Ideologies tend to having an **internal** rationality, becoming impervious to any concept or even **event** that does not seem to fit within their limits. They are **regulation mechanisms** and can, during long time, foster cultural **identity**. They nonetheless may impair the **perception** of discrepancies or **changes** and finally lead the system to a critical **threshold** of **instability**.

1612

IDONEITY³⁾

Fitness, or relevance of **models** and theories, in relation to reality.

This concept was developed by the Swiss epistemologist F. GONSETH in his epistemological study of the evolution of geometry in the 19th and 20th Centuries. It has been reintroduced by E. SCHWARZ (1994 b, p.581).

1613

IF – THEN

→ **RULE (If – Then)**

1614

IIASA

→ **International Institute for Applied Systems Analysis**

1615

IMAGE^{2) – 3)}

A physical or mental **representation** of some **object** or system.

Physical **representations** are generally "**iconic**", made to be seen. Mental **representations** are proper to each individual. Image formation is, at least in man (if not altogether in superior animals), a basic condition for coordinated **action**.

In J.P. CHANGEUX words, images do result of the "...integrated workings of a **perception mechanism** of mental **objects** and of monitoring or their **connections**" (1992, p.709)

When the **relationship** between mental and psychic images and the relevant **environment** is unsatisfactory, **action** turns inefficient, and in some cases outright pathological, in particular when the image is confused with what we call reality (A. KORZYBSKI, 1950a). Images are a fertile ground of **metaphors** and **analogies**, sometimes unfortunately dubious or spurious.

As observed by K. BOULDING (1956), mental images have an imaginary temporal dimension, when referred to past **events**, even those historical ones whose images had to be learned, being built up through **semantic** or **symbolic messages**: None of us ever knew personally

¹⁾general information

²⁾methodology or model

³⁾epistemology, ontology and semantics

⁴⁾human sciences

⁵⁾discipline oriented

Julius CAESAR, but we assembled an image of him, learned from historical records, transmitted through successive generations... and very probably quite inaccurate in some aspects.

1616

IMAGES: their meaning in societies²⁾⁴⁾

K. BAUSCH describes as follows the present nature and **role** of images in societies. Thereafter he presents a proposal for their use as a possible tool for social **transformation**, as elaborated by a growing group of systemists concerned with better working human societies. BAUSCH starts by defining "images" present meaning: "The subjective and intersubjective **knowledge** (i.e. what we believe to be true or possible) that guides individual **behavior** and shapes collective **culture**" (Glossary-Per-s.comm., 2002)

He explains: "Images of humankind which are dominant in a culture are of fundamental importance, because they underlie the ways in which the society shapes its institutions, educates its young, and goes about whatever it perceives its business to be. The image represent our current **perception** of the past, present and future.

Our social realities and our images coexist in mutually adapting **interaction**" (Ibid)

These are the images that we have and use. Could we change this scheme purposefully? Hereafter BAUSCH's opinion. "The **purpose** of an evolutionary image is to guide out attention toward a desirable future-rather than to try to predict the future based on an **extrapolation** from past and present **events**. An evolutionary image of the future is an invitation to become **aware** of the consequences of our present **choices**, and more importantly, to participate in the creation of the future. The absence of such an image restricts the human potential and our future possibilities" (Ibid).

However, the use of valorative terms (believe, true, desirable), which are culturally tainted, and the possible effects of their use, should be closely scrutinized. This is specially important as we are now in a **process** of multi-cultural debate as a result of so-called **globalization**.

1617

IMITATION^{3) - 4)}

Acquisition of a **model** for **behavior** by **perception** of the **behavior** of another **organism** (after D.T. CAMPBELL, 1961, p.18).

Imitation is also, obviously a mode of social **learning**.

Not only people, but also many animals acquire some typical behavior by imitation, which is generally basic for most of the process of **learning**. E. CURIO even managed to induce sequential imitation among blackbirds, of an initially conditioned behavior in a first bird of the group (L.A. DUGATKIN, 2000, p.55).

Simple imitation of some specific behavior is not sufficient however to explain transmission of **culture** (H. PLOTKIN, 2000, p.60). But this transmission supposes such individual and elemental steps as a first basic repeated **process** covering the acquisition of the numerous correlated traits that make up a **culture**.

→ **Time binding**

1618

IMMERGENT PROPERTY^{2) - 4)}

A property of an **element** or **subsystem** that becomes concealed at a higher **level** in the system.

A good and simple example is the concealment of the specific properties of the oxygen atom or molecule within the H₂O molecule. Immergent properties are a natural complement of **emergent** ones.

Immergence is a general characteristic of all **elements** entering in combinations within more complex units: it is practically a very basic social property.

1619

IMMUNITY^{1) - 4) - 5)}

The condition of a system able to resist some specific aggressions from other systems in its **environment**.

This is a generalization of the biological concept of immunity. This condition is a result from a first successful **reaction** of the system to the aggression, through some internal **adaptation**.

Immunity results in general terms from the **emergence** of a countervailing **feedback** that becomes stabilized, generally in an implicit way.

In a somewhat metaphorical way, social and cultural systems may become more or less immune to foreign influences by developing defense **mechanisms**. This is probably the unconscious aim of what is generally known as fundamentalism, as an adaptive **reaction** to psycho-cultural suffering, induced by some imposed transformation.

→ **"Resilience"**.

1620

IMPEDANCE (Active)²⁾

A device developing "...a backforce against any **input** driving force so long as that force is increased" (H. ODUM, 1971, p.39).

This could be called a device for stubborn resistance and protection. ODUM, who describes it, writes: "At the same time some **energy storage** is arranged so that when the forcing

impetus ceases, the **energy** unit delivers a forward **flow**. Many **organisms**, human **behavior programs**, and conservative institutional **programs** have stubbornness of this form" (Ibid).

1621

IMPLICITNESS³⁾

The hidden character of much of the fundamentals of our **concepts** and **methods**.

This difficulty has been emphasized by J. WARFIELD who underlined that it works against the transparency of our referentials (1988, p.340). See: **"Invisibility"**, **"Underconceptualization"**.

1622

IMPLOSION²⁾

A sudden and more or less complete inward **collapse** of a group of **elements**.

This **process** may create a system out of formerly unconnected **elements**, as for example in a star's formation; or a quasi system as for instance a locusts **swarm**. According to B. WALLISER it corresponds to the increase of the **interactions** among **elements** (1977, p.84).

It leads to growing reciprocal **constraints** through an increasing number of new associations that tend to become **correlated**, as well as **structurally** and **functionally** permanent.

It is however also possible that an excess of **constraints** could produce a more or less total freeze of the **interrelations**, leading to a kind of blockage or paralysis and ensuing destruction.

→ **Frozen core**

1623

IMPRINTING:¹⁾⁴⁾⁵⁾

A **learning** or **training process** during the early life of an animal through which a specific behavior or **behavioral pattern** is acquired through **imitation** from a parent or other member of the **social group**.

The basic **behavior** of an animal becomes fixed normally by **imitation** of its parents, or other members of the social group. Imprinting occurs only during a quite short critical **period**, during the early weeks or months of an animal.

This very general behavior has been observed and researched mainly by the Austrian Konrad LORENZ, and the Dutch Niko TINBERGEN, pioneers in ethology.

In this way, basic reactions, as for example escape from predators become deeply ingrained and automatic, which is a very important life-saving **adaptation**.

Ethology of imprinting, as a trans-generational process, opens interesting question marks on the possible existence of a wider, cultural type of imprinting in humans. Doubtless, a

whole range of **reactions** and ways of behaving are learned during human infancy. and they seem to be different from one **culture** to another.

The human being is quite probably the most deeply and widely imprinted living being, as **culture** includes not only physiological behaviors, but also transmits attitudes and **roles**

The subject would deserve a deeper scrutiny by ethnologists and sociologists, as it seems to indicate general definitory **rules** for the establishment of implicitly well defined **relationships**, even in some cases in an automatic, if not coercitive way.

An interesting line somehow related to imprinting is J.L. MORENO's sociometry, including his sociograms.

1624

IMPROBABILITY (Degree of)¹⁾

The degree of improbability of a system is proportional to the **complexity** of the **interrelations** among its **elements** and to the number of its possible **states** (**variety**). It measures the quantity of **information** that should be needed to assemble it and the improbability that could be introduced by **random** action.

Thus improbability is not related only to **synchronic structure**, but altogether with its **diachronic** variations.

1625

INCHOATE BONDING MECHANISM

→ **Bonding mechanism (Inchoate)**

1626

INCLUSION CYCLE

→ **Cycle (Inclusion)**

1627

INCOMMENSURABILITY²⁾

P. BERGÉ and M. DUBOIS state: "A **nonlinear dynamic system** that **oscillates** on three incommensurable **frequencies** may become **unstable** and show a **chaotic behavior**" (1992, p.120).

The subject of incommensurability deserves wider research because it is a bridge between **chaos** and **prime numbers**. Intertwined **periods** each with a **frequency** based on a **prime number** could be the basic characteristic of **chaos**.

This could also prove an interesting return to PYTHAGORAS and FIBONACCI.

1628

INCOMPATIBILITY (Principle of)¹⁾

This principle has been proposed by L.A ZADEH who stated it in the following terms: "... as the **complexity** of a system increases our ability to make precise and yet significant statements about its **behavior** diminishes until a **threshold**

is reached beyond which precision and significance (or **relevance**) become almost mutually exclusive characteristics".

Moreover, "A corollary principle may be stated succinctly as: "The closer one looks at a real-world problem, the **fuzzier** becomes its solution" (1973b, p.28).

Consequently, in ZADEH's opinion: "... the conventional quantitative techniques of **system analysis** are intrinsically unsuited for dealing with humanistic systems or, for that matter, any system whose **complexity** is comparable to that of humanistic systems" (Ibid).

This has been the reason why ZADEH introduced the concepts of **fuzzy** logics.

It is noteworthy that these seem to apply basically to systems whose **behavior** is **chaotic**.

1629

INCREMENTALISM (Disjoined)^{1) - 4)}

Small **changes** introduced in a system, based on inadequate **information** and **understanding** (Adapted from J.van GIGCH, 1978, p.360).

This concept has been introduced by D. BRAYBROOKE & C.E. LINDBLOM (1963), according to whom it is characterized by **decisions** "subject to constant reconsideration and redirection... typical of ordinary political life". They state that, as most political **decisions** are based on small incremental **changes**, "old programs go on to being developed into new programs as a sequence of **decisions**". Such a new program "is not a program at all; it is not a comprehensively considered and coordinated policy". Rather "it is the product of a number of small specific moves... whereby old programs are modified through... an endless stream... of **decisions**" (as quoted by J.van GIGCH, p. 360).

This kind of ad hoc tinkering is of course anti-systemic, and is the main cause of global **suboptimization**, squandering and pathological bureaucratization.

This problem is closely related to J. WARFIELD's **underconceptualization**.

1630

INDEPENDENCE¹⁾

The quality of a totally self-supporting system.

This is an abstract and quite illusory **concept**, which should be paired with the **concept** of **isolated system**. No **concrete system** can survive without **inputs** (and **outputs**) of **energy**, **matter** and/or **information**.

K. KRIPPENDORFF states that "Independent systems are closed to **information**" (1986, p.38). One wonders if such a condition is really possible for **concrete systems**. A system could be independent of others only if it has never interacted with them, and will never do.

Independence, moreover, should not be confused with **autopoiesis** and its complement **organizational closure**, which are properties allowing a system to maintain its **autonomy**, i.e. to **control** more or less efficiently its **interrelations** with its **environment**.

→ **Interdependence; Rights and responsibilities**

1631

INDETERMINACY^{1) - 2)}

Condition of a system such as "...there exist no determining formula whereby future **state descriptions** are completely and necessarily implied by present **data**" (D. Mac KAY, 1969, p.147).

Mac KAY understands that indeterminacy is a condition more extreme than **unpredictability**, which may result when a "completely determining formula" exists, but with an insufficient **knowledge** of the "relevant **initial conditions**" or insufficient computing capacity.

It is arguable if "indetermined" means "totally indeterminable". **Complex systems** with a number of independent initial **variables** (i.e. initially independent) may be submitted to a general **determinism**, which however allows for numerous unpredictable **situations** within its own **limits**.

This is the **chaotic determinism situation**.

1632

INDETERMINACY (Macroscopic)^{1) - 2)}

According to I. PRIGOGINE et al., a consequence of the **thermodynamics of irreversible systems far-from-equilibrium** is that: "... the macroscopic equations themselves contain the element of stochasticity which leads to "macroscopic indeterminacy". Problems such as **self-organization in nonequilibrium systems** require both aspects – the **deterministic** one where averages represent accurately the physical **state** of the system, and the stochastic one which is important near **bifurcation** points and **instabilities**. It is the cooperation of these two features which leads to a faithful **representation** of some of the basic aspects of evolving systems" (1978,p.72).

1633

INDETERMINACY RELATION (Heisenberg)^{3) - 5)}

In relation to the **complementarity** situation in micro-physics stating the **simultaneous** but incompatible (in the classical physics sense) ondulatory or corpuscular aspects of microphysical entities (radiations-electrons), HEISENBERG "...showed how a high precision in the determination of one property x (e.g. position) implies a low precision in the determination of a **complementary** or incompatible property p . (e.g., momentum)

$$m \cdot \Delta x \cdot \Delta p \geq h/4\pi$$

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

"m is the mass of the particle. Δx is here the uncertainty in the determination of x., h is PLANCK's constant. The product $\Delta x \cdot \Delta p$ determines a volume in **phase space**. Hence, the principle (of indeterminacy) can be interpreted as saying that no **measurement**, however precise, can distinguish a part of **phase space** smaller than the volume" (F. HEYLIGHEN, 1990b, p.479).

The indeterminacy relation, is frequently presented as the "**uncertainty principle**" (even by HEISENBERG himself!), which allows for metaphorical "psychologized" interpretations that should be carefully scrutinized.

K. BOULDING considers that "Physical systems in the small range, biological systems in the middle range, and **social systems** throughout their whole range are of ... probabilistic nature, and have... Heisenberg principle built right into them. ...For Heisenberg systems where **information** and the **observer** are of the same order of the **magnitude** of the system, and for the closely related probabilistic systems, the method of **general systems** is a necessity" (1964, p.35).

Recently, D. DUBOIS emitted the hypothesis that "As velocity is the temporal derivative of a particle's position, if the particle follows a **fractal**, i.e. broken, **trajectory**, it is impossible to know its precise velocity when well localized. The alternative should be considering **space-time** as of **fractal** nature, in which case it would not be **continuous**, but discrete" (1990, p.109).

In short, there is no easy way out of indeterminacy.

1634

INDETERMINACY RELATION: The Copenhagen Interpretation⁵⁾

F. SUPPE summarizes it as follows:

"Exploiting the fact that microscopic particles sometimes act like corpuscles and sometimes like waves, the HEISENBERG indeterminacy relation is interpreted as showing the impossibility of measuring a physical quantity without causing a **disturbance**. Any attempt to improve the **measurement** of a **parameter** which characterizes a system will have the inevitable result of disturbing the value of another **parameter** of the system: unlike the macroscopic **level**, on the microscopic **level** these **disturbances** will be non-negligible; thus it is impossible to find the position and velocity of a subatomic particle at one moment with complete accuracy" (1978, p.182).

Indeed, at the **macroscopic level**, velocity is measured by comparing two or more successive positions, which implies that in these cases measurement of position and velocity, while accurate, cannot be really **simultaneous**. The real difference with microscopic particles is that here the system's **identity** is not significantly affected.

1635

INDEX

→ **Semiotics**

1636

INDICATION^{2) - 3)}

"...a marking of the two distinguished **states** as being primary ("this", "I", "us", etc.)" (J.A. GOGUEN and F.J. VARELA, 1979, p.32).

These authors observe: "... indeed it is the very **purpose** of the **distinction** to create this indication" (Ibid).

The **purpose** is, of course, the **observer's** one. Thus, "an **observer** can make a **distinction** into an indication through the imposition of his **value**" and, "Conversely, the **distinctions** made reveal the cognitive capabilities of the **distinction**" (Ibid).

From another viewpoint: "It seems to be a general reflexion of the richness of natural systems that indication can be iterated to produce a **hierarchy of levels**" (p.33)

→ **Calculus of indications**

1637

INDIVIDUAL¹⁾⁴⁾

LUHMANN defines an individual (or person) as a "social identification of a complex of expectations oriented through a single man" (1984, p. 286), and a person is "a **structure** in the **auto-poiesis of social systems**" (1990, p. 33)

These quite abstract definitions show the very special position of the individual, who is in **structural coupling** simultaneously with his/her **environment**, with his/her society and him/her self.

These same characteristics can also be observed in animal societies (migratory locusts, termites, ants, bees, etc) But in these cases it would be very questionable to name individuals as persons, because of the scant development of their **brains**.

1638

INDIVIDUAL SPACE

→ **Proxemics**

1639

INDIVISIBILITY OF GLOBAL PROCESSES^{1) - 3)}

In his critique of the EINSTEIN, ROSEN and PODOLSKY paradox, N. BOHR "... argued that in the quantum domain the procedure by which we analyse classical systems into interacting **parts** breaks down, for whenever two entities combine to form a single system (even only for a limited period of **time**) the **process** by which they do is not divisible. We are therefore faced with a breakdown of our customary idea about the indefinite analysability of each **process** in various **parts**, located in different **regions** of **space** and **time**. Only in the classical limit,

where many quanta are involved, can the effects of this indivisibility be neglected" (D. BOHM, 1980, p.73).

Thus *indivisibility is another interesting formulation about the limits of reductionism*. It has also important implications for the dubious way we **dichotomize** our most basic **concepts** as **time**, **space**, **matter** and **energy**.

It can however be argued that the indivisibility problem may surge at *any complexity level*, and not merely at the quantum **level**. In all cases it is a result of multiple *simultaneous interactions* among numerous **elements**.

→ **3 bodies problem**

1640

INDUCER²⁾

A **process** which facilitates the needed **response**.

This term has been coined by R. ROSEN, who also uses the opposite one: **repressor**, and stated that, in a **network**, "... the **behavior** is always the outcome of an **interaction** of pairs of antagonistic activities, one of which excites a particular **response**, and the other of which inhibits it" (1974, p.171).

→ **Agonistics, Antagonism Principle**

1641

INDUCTION²⁾

1. The production by a **message** of a specific **reaction** in a receiving **element**.

Interactions seem to be inductive by their very nature. Nothing at all should happen if the receiving **element** would not be able to decipher the **signal**.

In biology, St. KAUFFMAN considers induction "as a basic intercellular conversation" (1993, p.540).

As the condition for deciphering **messages** must preexist, induction seems to depend somehow from **organizational closure**, or **autopoiesis**.

2. The obtention by reason of a general statement or **law** from repeated **observations**.

Or, in R. AXELROD's words: "Induction is the discovery of **patterns** in empirical **data**" (1997, p.17)

"For example, in the social sciences, induction is widely used in the analysis of opinion surveys and the macroeconomic **data**" (Ibid)

According to E.von GLASERSFELD: "... induction, whether it is conscious in the form of a conclusion we draw, or unconscious, in the form of a **behavior** that becomes established because of its success, springs always from the same root: a more or less regular recurrence in past experience" (1988, p.43).

On induction as a human mental faculty, POPPER proposed to construct an induction **machine** that "could by repetition "learn" or even "formulate", **laws** of succession which hold in its "world"... However he immediately

criticized his own argument, stating that: "In constructing an induction **machine** we, the architects of the **machine**, must decide *a priori* what constitutes its "world", what things are to be taken as similar or equal; and what kind of "laws" we wish the **machine** to be able to "discover" in its "world" (Quoted by L. LÖFGREN, 1993, p.104).

As observed in turn by LÖFGREN, quoting TARSKI and GÖDEL, this is still another case of the fact "that there is no **language** admitting a theory with its own **truth** predicate" (p.105).

This is coincidental with Ch.S. PEIRCE statement that "induction has its role not in the forming of hypotheses, but (in certain **fields**) in testing the hypotheses arrived at by abductive **inference**" (as quoted by P.R. MASANI, 1994, p. 45)

Abduction is thus the "prime mover", followed by induction as "the inference corresponding to the **habit**-forming aspect of the mind, and **deduction** is the inference corresponding to the volitional aspect of the mind (Ibid, p. 46)

In all three stages- but to begin with the abduction process- a pre-active involvement of the scientist mind (see the discussion of this term) is always present (Ibid, p. 47)

We may also observe that the "receiving **element**" of the definition could not decipher any **message** without counting with the adequate **code**, which comes to the same as POPPER's argument.

1642

INDUCTION (Principle of) ¹⁾³⁾

"The future will in certain respects resemble the past" (J. BRYANT, 1991, p. 150)

This means that induction, as a **meaning** creation **process**, implies a hidden **belief** in coherent and stable correspondances between some **observations**, stored **memories** and **reference frames**

BRYANT expresses this as follows: "...induction may be explained as the product of **neural linkage** between **engrams**, or, in psychological terms, as **associations** between ideas" (p. 117 and 150-51)

This is very different from the **deduction process** which in BRYANT terms "...is the act of making an engram generalization from the premises "or..." the process of deriving statements (called *deductive conclusions*) from some *fixed set* of statements (called *deductive premises*)" (Ibid)

Induction creates new combinations, that normally lead to modifications in **frames of references**

Deduction merely explicits already existing **implicit knowledge**

→ **Abduction**

1643

INDUSTRIAL DYNAMICS ^{2) - 5)}

A computer-based technique of **modelization** of complex business and industrial firms.

Industrial Dynamics was proposed by J. FORRESTER, of the M.I.T (1961), and later on extended to socio-economic and socio-ecological systems in general (See "**Club of Rome**", "**Systems Dynamics**").

The I.D. **models** are expressed in DYNAMO, a computer **simulation language**, also developed at M.I.T.

I.D. **modelization** is generally based on interconnected **feedbacks** between a number of **variables** considered to be basic for the **adaptation** and **evolution** of the system under study. It produces important insights into the **causes** and **effects** of **disturbances** in **processes**, their propagation, their more or less **cyclical** character and their final impact on the **stability** of the system.

However, the selection of the **variables** to be considered, the definitions about their **relationships** and the **reliability** of the collected **data** may all be controversial (Ch. FRANÇOIS, 1977).

Also J.van GIGCH observed (quoting I. ANSOFF & D.P. SLEVIN, 1968, p.395): "Industrial Dynamics has been criticized because it is not "a theory" in the sense of providing 1) "**predictions** about relations of **variables** which have not been previously observed" and 2) "a verification of **validity** of the theory through comparison of relations established in theory with observable relations in the real world" (1978, p.330).

FORRESTER himself rightly observes: "Like all **simulations**, the "**behavior**" of the system is dependent on the **structure** of the **model's** equations. As such "Industrial Dynamics" deals with **closed systems**. This means that the **behavior modes** of interest are generated within the **boundaries** of the desired system" (1961, p.406).

In synthesis, any result obtained is implicit within the **model** as it has been constructed, which however does not diminish the interest of revealing probably unsuspected **behavior modes**. I.D. models have a kind of **organizational closure**.

1644

INERTIA ¹⁾

Resistance to **change**.

Most systems possess their characteristic inertia, which can be physical, chemical, ecological, psychological, economical, or socio-cultural.

This property corresponds to the existence of **thresholds of stability** under which no decisive **change** can take place. Even simple **adaptation** is frequently met with long inertial resistance.

Inertia seems to correspond to the presence of **negative feedbacks** that are able to maintain **stability** as long as they count with **reserves** to compensate **deviations**.

Unheeded inertia can lead to a false appreciation of the **adaptation** possibilities of a system. Conversely, to believe uncritically in inertia, especially of **ecosystems** and **sociosystems**, may well induce a false belief in inherent **stability** of the same.

1645

INFERENCE ^{1) - 3) - 4)}

"The production of one or more beliefs or assumptions by one or more other beliefs or assumptions" (R.L. ACKOFF & F.E. EMERY, 1972, p.113)

But, to begin with, wherefrom came the first beliefs or assumptions? Cultural nurturing seems to play an important role in the ways "... **signs** denote what they do on the three principles of resemblance, **contiguity** and **causality**" (C.S. PEIRCE, in 1991, p.80).

In any case, the **recursive** definition given by ACKOFF and EMERY is justified as follows by these authors: "... there is a **set** of beliefs and assumptions that the **subject** is willing initially to accept as true. These beliefs and assumptions contain only **elements** of the system and are expressible consistently with the formation **rules**. These **rules** constitutes the *premises* of the system. In a deductive system these premises may be axioms or postulates; in an inductive system they may be a **set** of accepted **facts** or **observations**" (Ibid).

This implies an important caveat for any systems **modelization**: Inference is related to **habit** formation and **habit** formation leads to uncritical attitudes.

1646

INFERENCE RULE ⁵⁾

"A rule that produces new **facts** on the basis of older ones" (E. BUCHBERGER, 1987, p.49).

Such rules are a basic feature of **expert systems**.

E. BUCHBERGER adds: "This results either from strong logic principles, or from incomplete, **heuristic** methods (inductive or deductive inferences)" (Ibid).

(Let us remember that "**facts**" are *constructed* by the **observer**).

1647

INFLECTION POINT ^{1) - 5)}

In mathematics, the point of a curve where the tangent crosses it.

The **logistic** curve, for example, has an inflection point where the acceleration factor becomes dominated by the braking one, i.e. where the **positive feedback** becomes slowed down by a **negative** one.

Inflection points are very important to observe because they signal a basic change of the **trend**.

1648

INFLEXIBILITY^{1) - 2)}

The condition of a system which loses its capacity of **adaptation or accomodation**.

As explained by C. HOLLING, there is always a trade-off between **stability** and **instability** in systems. **Dynamic stability** is an advantageous and economic state of affairs as long as its basic **environmental** conditions are maintained. When such conditions persist for a very long time, the system is however at risk to "forget" possible **responses** to strong and infrequent **perturbations**.

HOLLING suggests that the **optimum** for any system is to possess alternative states of **dynamic stability** (or **domains of attraction**), through which it may switch when necessary. He gives numerous ecological examples of **flexibility** in **populations of living systems** which are endowed with this type of **flexibility**. (1976, 1986).

1649

INFOLDING²⁾

The **emergence** of a new **level of complexity** *within* a system undergoing a **process of dissipative structuration**.

This term has been proposed by C. JOSLYN, who writes: "We usually think about **emergent phenomena** as entering at the "pinnacle" of some **evolutionary hierarchy**. In contrast, we regard this kind of **emergence** not as adding a **layer** on top of a **hierarchy**, but rather as a "deepening" of "in-folding" of an existent **hierarchy**. The new **level** is added between what was previously (and still is) the bottom and the top **levels**" (1991, p.639).

For example, the **emergence** of a highly developed neo-cortex in the human **brain** is a result of internal differentiation of an existing **structure**. This example however seems to indicate that such an "in-folding" may lead in some cases to the **emergence** of a new and **higher level of complexity** in a different sense: **numerous** individuals endowed with these evolved **brains** are able to create social **organization** on a new innovative **level**.

1650

INFON¹⁾³⁾

"A postulated general **information** particle". S. BRIER, in his review of T. TONER's book on "Information and **Meaning**" discussed the proposed new term (1998, p. 82)

He writes: "The Infon is defined very much along the lines of how originally in the sciences the conceptualization of human work has reduced to form the general concept of **energy** in nature".

Reflecting on the progressive use, extension and deepening concept of energy, for comparison, BRIER observes that this was a productive, but quite strenuous **process** because it took place within the **mechanistic framework** of 19th Century science. He adds similar comments about the difficult progress of Planck's quantum during the 20th Century.

It is clear that the different forms of **information transmission** (**languages**, the semiochemicals (another neologism!) electronic devices have a basic common feature...whose deeper meaning could probably need many more years to be better understood.

For now BRIER is questioning "the fruitfulness of the objective informational approach to give us a **framework** that can solve our problems of **understanding evolution**, intelligence, **consciousness**, **man-machine** interface and cooperation, plus the enlightenment of our understanding of signification and **information** processing in general" (p.85)

1651

INFORMATICS⁵⁾

Everything that has to do with **information** processing by **digital** computers.

This term is used mainly in Europe and in Latin America ("Informática")

K. KRIPPENDORFF writes that Informatics "includes (the largely U.S.) **computer science**, the more application oriented efforts of **management information** systems, **automation** of production but also **data processing** including statistics for **decision making**".

He adds: "Because of its technological commitments, informatics has desensitized the study of **information flows** and computation within **organisms** and largely ignored the organizational consequences of **information flows**, **human communication** and the use of computers in large **social systems**" (1986, p.38).

1652

IN - FORMATION¹⁾

Progressive internal **structuration** of a system.

This should be taken as a systemic etymological exploration of **meanings**!

Any **complex system** seems to start with a basic **program**, or **grammar** of **rules** which endows it with its proper, unique and permanent **identity** (**organizational closure**) However, internal **structuration** results of a progressive build-up, through the **interaction** of the **program** with the basic or circumstantial **environment**.

This is specially true of man as thus expressed by L. THAYER: "...all other creatures enter the world essentially *pre-formed* to take into account that which they can and must. Not

so, man. He must be *in-formed*, and this, by his fellows. What is therefore real, important, relevant, etc., for man must be learned by him (or "taught" to him). A common cricket is merely **informed** by certain **signals** which he has been **pre-formed** to receive and respond to. A man is both informed and *in-formed*. Because he has received and acted upon it once, no "**message**" will ever be exactly the same to him again. A man evolves as a human out of his **communication** experiences. He is irreversibly altered" (1972, p.105-6).

1653

INFORMATION^{1) - 3)}

1) "The **content** of a **message** apt to trigger some **action**" (J.de ROSNAY, 1975, p.168).

In this view, as stated by W.R. WINBURN, "information is "the **difference** that makes a **difference**" (1991, p.558).

The definition given by J.de ROSNAY is a most general, and pragmatic one.

It opens however some intriguing questions, as shown by the following example: A sculptor starts his/her work on some block of stone. The "information" is what she or he has in mind (let us not here inquire wherefrom it came!). The work progresses through the sculptor "**message**" to the stone, by hewing slowly some face or figure out of it. The **message** is transmitted through the nervous and muscular system of the sculptor and the chisels.

The "**receiver**" is the stone, but it is quite a passive, not an active one. Such is the mystery of the creative act. It is kind of a **message** of the creator to some passive material, which thereafter acquire a power, becomes a bearer of information as the creator communicates with him or herself and to others through the "informed" material, which is now "informative".

On the other hand, **many receivers** can be directly activated by a **message** (see for example "**selective content of information**").

In J.de ROSNAY words: "Aristotle introduces an important **distinction** between both **meanings** of the word information. On the one hand, information is understood as "acquisition of **knowledge**" (it is the act to inform oneself by observing some **object** or nature). On the other hand, information means "power of **organization**" or "creative **action**" (p.168).

2) A more or less organized **set of data** transmitted from one intelligent system to another.

Information, sometimes confused with its **communication**, is not merely basic to systemic **methodology**, but altogether a central and many-sided systemic **concept**.

1- Information exists within informed systems, i.e. organized entities able to translate some basic **data** into coherent **action**.

2- Information has a specific human **meaning**.
 3- Information "is descriptive: it is contained in answers to questions that begin with such words as What, Which, Who, How many, When and Where" (J. GHARAJEDAGHI, 1985)

4- It has moreover a **semantic meaning** (Mac KAY's "**logon**"), different from its quantitative measure.

5- However, information can also be measured and, in this quantitative sense used to dispel some degree of **uncertainty**.

→ "**Entropy versus Improbability**".

6- It can be related to the increase or local decrease of **entropy** production, i.e. tipify degrees of systemic **organization**.

The concept of information has been quite enriched, but, alas, also muddled as a result of the development of computer science (**informatics**).

Confusion started when C. SHANNON published his "**Theory of Communication**", which nearly everybody calls erroneously, a "Theory of Information". As an electrical engineer working for a telephone company, his basic purpose was to investigate the *communication* of information through a **channel**, namely at the time telephone wiring.

On this specific aspect Mac KAY writes: "A further question was where, if anywhere, the notion of "**meaning**" fitted into the scheme of things. SHANNON's analysis of the "**amount of information**" in a **signal**, which disclaimed explicitly any concern with its **meaning**, was widely misinterpreted to imply that the engineers had defined a *concept* of information per se that was totally divorced from that of **meaning**" (1969, p.5).

As to what information really means, we may quote T.S. Eliot who asked somewhere: "Where is the **knowledge** we lost with information? Where is the wisdom we lost with **knowledge**?" Possibly, some deciders would add: "Where is the information we lost with **data**?" Indeed, during the last 40 years the technology of information **transmission** and treatment has seriously obscured the problem of **meaning**, in its different guises.

Data cannot be transformed into information by *themselves*. Whatever is offered by a newspaper, a radio or a T.V. set, or a computer, is merely raw material, which acquires significance only when integrated within a **frame of reference**. Thus, only a modicum of previous **knowledge**, offering such a frame can transform **data** into information. In turn, this information may then transform or expand pre-existing **knowledge**, for example through a Popperian process of falseation (for which **meta-rules** are needed). Finally, the proper uses of

well-informed **knowledge** is ELIOT's wisdom, as a **meta-frame of reference**.

A massive flood of **data**, even ordered in some base, merely overwhelms the best minds if not organized within a well defined **frame of reference** and sustained by clearly stated **purposes**.

Using adequate physical and semantic **codes**, we communicate our **observations** and our interpretations to other people, in order to:

- confirm, correct or invalidate what we did register or conclude;
- obtain **feedback** in order to complement our own results;
- seek a **consensus** leading to common **understanding** and collective **action**;

Only after such constantly renewed exchange, we may speak of "information" referring us to confirmed and circulating **meanings** admitted by some specific **group** of people. Moreover, information becomes **knowledge** only when organized within a net of interconnected **meanings** whose **coherence** is generally recognized after due testing and **confirmation** by numerous people and during a long span of **time**. This is the **social frame of reference**.

As a still tentative synthesis, "information" is a many-sided concept, conveying by natural or artificial means collective **sets** of quite various **representations** acquired by **consensus** within specific **groups** of people.

It necessarily implies a **network** of interactive **elements**, whose **interactions** first *create* **rules** and thereafter *obey* them. This supposes **change**, i.e. a **space-time flow**. Such an **understanding** is less psychologically oriented, while still, unavoidably anthropocentric.

As such, the concept can be used in many different ways, if we keep in mind that its value is relative and that we must define clearly, in every case, what **frame of reference** we are using.

3) "That which adds to a **representation**" (Mac KAY, 1969, p.163).

Mac KAY comments: "...this leaves open the possibility that the information may be true or false. When a **representation** alters, we define the new information as true if the **change** increases the extent of correspondence between the **representation** and the original.

"The information is said to be false if the **change** diminishes the extent of this correspondence. Strictly, the **truth** or falsehood is an attribute of the resultant **representation**, but it is customary to attribute it to that which has given rise to the **change** in the **representation**" (p.163).

4) "...that which does logical work on the **organism's** orientation (Mac KAY, 1969, p.96).

Mac KAY adds in this case: "(Whether correctly or not, and whether by adding to, replacing or confirming the functional **linkages** of the orienting system)" and "...Thus we leave open the question whether the information is true or false, corrective or confirmatory, and so on" (Ibid).

5) "A measure of **selection** among a given **set** of possibilities" and also "Sometimes a measure of the extent to which **uncertainty** is reduced" (G. PASK, 1961, p.115).

"A **message** that produces a **change** in any of the **receiver's** probabilities of **choice**" (Adapted from R.L. ACKOFF & F.E. EMERY, 1972, p.144).

These last authors state: "Because of the pervasiveness of the use of information in the restricted (technical) sense of SHANNON's information theory (SHANNON and WEAVER, 1949), it might seem preferable to use another term here. But since the way that we use information here conforms more closely to common usage than does SHANNON's, if a change is required it would seem preferable to change SHANNON's term". Let us remember that that part of SHANNON's theory is of quantitative nature" (Ibid).

The same authors quote C. CHERRY who wrote: "In a sense, it is a pity that the mathematical concepts stemming from HARTLEY have been called "information" at all. The formula for H_n is really a measure of one facet only of the concept of information; it is the statistical rarity or "surprise **value**" of a source of **signs**" (1957, p.50).

A. RAPOPORT states: "The **concept** of information is as central in **cybernetics** and **communication** engineering as the concept of **energy** is in classical physics.

"**Energy** has been the unifying concept underlying all physical **phenomena** involving work and heat. Information became the unifying concept underlying the working of organized systems, i.e. systems whose **behavior** was under **control** so as to achieve some pre-set **goals**" (1966, p.5).

As may be appreciated, this very fundamental aspect is merely implicit in PASK's and EMERY and ACKOFF's definitions.

P.S. HENSHAW explains: "Information is an entity apart from the means by which it is processed, the **symbols** by which it is represented, or the **responses** made to it. **Messages** contain intelligence (dispositional, organized, usable and available information), but as such do not themselves constitute intelligence.

"Information can be transmitted and stored by means of impulses and **symbols**, but it exerts an influence only after removal from the encoded **message** and **interaction** with other information, as can happen in a **cell**, a **brain** or a computer...

"Information as such is not amenable to quantification in a manner comparable with that which applies to entities having force, mass and charge.

"In the last analysis, information consists of **data**, especially unrelated **facts** and statistics. With **organization of data**, intelligence is created and with further **organization** of organized **data**, intelligence is developed and advanced" (1975, p.18).

It seems that HENSHAW uses the term "intelligence" in the sense of "**understanding**".

Moreover, information "... can be created and destroyed" (p.18). This is also ambiguous. What can be destroyed are raw **data**, or organized **sets of data**, or the results of the treatment of **data**, or even some forms of **understanding** of these results.

In effect some original **rules of organization of perceptions** are needed in order to obtain **organization of data**, and that both kind of **organization** must become constructed as properties of a progressively self-constructed **network**.

1654

INFORMATION (Amount of) ⁵⁾

"A logarithmic measure of the statistical unexpectedness (reciprocal of probability) of the **message** concerned" (D. Mac KAY 1969, p.79).

Mac KAY states: "Since the unexpectedness of a **message** need not have direct **connection** with its **semantic content** or **meaning**, SHANNON wisely insisted that the concept of "**meaning**" was outside the scope of his theory" (Ibid).

Basically and inasmuch as SHANNON's work is related to information, it should be definitely understood that it is about quantitative information and its **measurement**.

"As an example let us suppose that we must select one object out of a collection, on the base of a specified criterion: for example the letter O within the alphabet. The most economical method is to divide the alphabet in two and ask: is O in the first half or in the second one? The answer provides us with one **bit** of information, corresponding to the fact that O is in the second half. Following in the same way, we now divide this second half in two and repeat our question. The answer: "O is in the first half of the second half" provides us with a second **bit** of information. Finally, we will find out that the number of **bits** we need to "place" O in the alphabet, is the logarithm base 2 of 26, i.e. 5 when rounded off to the next whole number of **bits**, taking in account that **bits** are necessarily whole numbers" (Ibid.).

This is in accordance with SHANNON and WEAVER, who consider the amount of information as a basically technical feature, which: "... characterizes the whole statistical nature of the information, and is not concerned with individual **messages**" (1949, p.104).

In this quantitative sense, information is thus defined as the logarithm to the base 2 of the possible combinations C, i.e.: $I = \log_2 C$. As logarithms are exponents, quantitative information is an **additive** measure of **complexity**.

Obviously, apart from the quantitative aspect of information, as expressed for example in **bits**, the qualitative aspect is quite a different matter, as it relates to **meanings**, which "make sense" only in exchanges between sentient and thinking beings, and not, for example, for the telephone sets themselves.

1655

INFORMATION and INFORMATION-CONTENT ^{1) - 5)}

D. Mac KAY states that a problem arises when information is confused with information content, i.e. "the confusion of a thing with a measure of a thing" (1969, p.56).

In his opinion: "**Communication** engineers have not developed a concept of information at all. They have developed a theory dealing explicitly with only one particular feature or aspect of **messages** "carrying" information - their unexpectedness or surprise value. Unexpectedness is a feature not only of **messages** but of other things, such as the **states** of a physical system. Physicists had already developed a quantitative method of measuring unexpectedness: by BOLTZMANN's statistical concept of **entropy**. What SHANNON and others did was to adopt and extend this method to the **measurement** of the unexpectedness of **messages**.

"Their measure of unexpectedness, the average logarithm of the improbability of the **message**, $-\delta p_1 \log p_1$, is not therefore information, but simply a particular measure of what they termed amount-of-information; (i.e.) the minuteness of the **selection** which the **message** makes from the **set...** of all possible **messages**".

"In this **set**, the different possible **messages** are pictured as occupying a space proportional to their relative probabilities, as that the least probable **message** occupies the smallest space and requires the most minute selective **operation**" (p.57).

1656

INFORMATION, as an energy modulation ¹⁾

It is sometimes forgotten that no information can be transmitted without an **energy** support of some kind. Moreover, this **energy** must be modulated, i.e. its **transmission** must be irregular, have some **rhythmic complexity** in form of a mix of **waves**. Thus the **energy-information dichotomy** is, in some sense a mental fabrication, becomes easily a quagmire, and should be used with care. In R.N. ADAMS words: "Information succeeds in stimulating, igniting, moving and more generally triggering

energetic **activity** because, and only because, it is also energetic **activity**... The insistence on dualism has inhibited exploring how the two were related" (1988, p.80).

In this sense, the insistence of BATESON on information as consisting only of abstract "**differences**" may lead to epistemological problems.

All that we have learnt about the different forms of **energy** confirms that it presents always a **variety of frequencies** and **amplitudes**. On the other hand, physical sciences and technology showed that such **frequencies** and **amplitudes** may be, or not, perceived by various natural organic **receptors**, which became adapted in a selective way to only some of them.

Moreover, present technology allows artificial **decoding of frequencies** and **amplitudes** that cannot be perceived organically, and their conversion into perceptible ones. In this way we succeed in transforming potential information into usable one. Such is the case with ultra and infrasounds, radio waves, ultra-violet and infra-red radiation, X-rays, gamma-rays, etc...

In all these cases, there is no doubt that information is carried along by energy. However, the origin of modulations and of our ability to perceive only some of them is still not so clear.

1657

INFORMATION COMPRESSION ^{2) - 3)}

J. S. WICKEN writes: "Basic to the definition of order is informational compressibility" (1979, p.139).

Unless we find a way to condensate the information **content** of a system, the only **model** of it is itself, which means that our rational **understanding** of it is nil.

WICKEN explains: "Two modes of information compression are possible. One is **algorithmic**. This applies to cases in which patterned **relationships** appear in a sequence that allows **element-by-element** specification to be replaced by a **program** of instructions for its assembly" (WICKEN adopts thus G. CHAITIN's concept of **algorithmic compression** of information, also known as KOLMOGOROV-CHAITIN **complexity**) (1975, p.47-52).

"For example, the sequence (1,2,3,4) possesses a higher degree of **order** than does the sequence (1,3,2,4) because a briefer **algorithm** is required to generate it.

"The second is probabilistic, and the compression is measured by the relative **values** of real **complexity** and maximum conceivable **complexity**. This **mode** of compression applies to stochastic **processes** in which (a) the **symbols** are not equiprobable and/or (b) the occurrence of one **symbol** in a sequence influences the probability of occurrence of other **symbols**" (p.139).

1658

INFORMATION: CONTEMPORARY MEANINGS¹⁾ - 3)

According to A. ZELEZNIKAR: "Today's **meaning** of information concerns **communication** or reception of **knowledge**, or intelligence. But information is also **knowledge** obtained from investigation, study or instruction, as well as **data** and facts.

"At least, it is becoming clear (that)...the contemporary **meaning** of information is developing as **form** and **process** in the entire **phenomenology** and how this **meaning** will still come into existence during new investigations" (1988, p.187).

One of the main features of information as we understand it nowadays is that the same observed **form** may imply different **meanings** for different **observers**, but also that different information may lead to the same **understanding** to one **observer**, or to various ones.

Some **meanings** given to "information" nowadays seem over-extended.

Has for example the so-called genetic "**code**" an information **content**? Does it transmit "information", or "**data**" to the **cells**? Or is it information only for the micro-biologist and the physician?

Another difficulty surges from a frequent confusion between information and **communication**. Many times Cl. SHANNON and W. WEAVER's "Theory of **communication**" is referred to as "Theory of information", while these authors limit themselves to a study of a **channel's** quantitative capacity to transmit **data**, the needed (quantitative) **redundancy** to compensate **noise**, and the number of **bits** needed to discriminate **elements** of information. There is nothing therein about **meanings** in a **semio-logic** or **semantic** sense.

G.R. JOHNSON denounces some abusive uses of "information" in social sciences: "Social scientists are usually interested in the content of a **communication**, not just in the number of **bits** that it takes to encode (it)... (Most of them) use the term "information" to mean something roughly equivalent to "ideas, beliefs, attitudes, **values**, and other nonmaterial stuff". Unfortunately, they often seem to confuse the two different uses of this single term. Impressed by the rigorous measurement of "information" as defined by **communications** engineers and **computer scientists**, a great many social scientists have deceived themselves into thinking that their own imprecise, ordinary **language** concept of "information" has been given scientific legitimacy. It has not..." (1992, p.1147).

(See ZELEZNIKAR's essay for many stimulating insights on information and its actual derivations as for example: "informative", "**informatics**", "informatizable", "informatization", "informational **processes**" and the relations of these **concepts** with neurology, **brain**, **behavior** and the **observer's** problem).

1659

INFORMATION COST¹⁾

As information always needs an energetic support, it is never free. It is however much cheaper to move information through **energy** pulses than to use **matter** as a carrier or a store. This fact is becoming very relevant for **human systems**.

1660

INFORMATION (Degradation of)^{1) - 2)}

J.de ROSNAY discusses in the following way the progressive degradation of information: "Information which circulates in a **channel** becomes irreversibly degraded. This implies a very significant **analogy** with **energy**, which degrades... through **entropy**. For example if we make a mold of some statue and cast from this mold another statue from which we make another mold, it is highly probable that after a score of successive operations of this kind, the final **form** of the statue will be highly distorted...

"To transmit information, **energy** must be spent. This energetic medium for information consists of light rays, sound waves, electric current in a telephone wire or the flight of the bee which transport pollen from one flower to another. This **energy** becomes weaker and scatters. It must be canalized and amplified. Moreover as the precision of some **measurement** needs to be greater, more **energy** must be spent" (1975, p. 169-170).

Thus is introduced the **interrelation** between **entropy** and information, both of which evolve in the **time** dimension.

→ ("**Information half-life**).

1661

INFORMATION (Distributed)²⁾

A situation in which information is carried by numerous **elements** of the system in a more or less redundant manner.

R. MARGALEF states: "Information ... is a property of everything that is formed of different **parts**" (1980, p.19).

Distributed information in **brain**, computers or natural or artificial social **networks** allow for better chances of **survival** of the system if part of the **network** is impaired. It is one of the basic characteristics of **heterarchical organization** and **loosely coupled systems**.

1662

INFORMATION DYNAMICS¹⁾

P.S. HENSHAW, after observing that: "**Self-organizing systems** are **energy**-information **input-processor-output** units, living or non-living, that are **adaptive**, **purposive** and discretionary", thus describes the basic features of information dynamics:

"1. Information seeks **consistency** ... in systems that have capacities for **memory**, **assimilation**, **integration**, and selective **energy distribution**, including **switching**, channeling and gating.

"2. Information interacting with information is generative...

"3. ...Accepting that information seeks **consistency**, it follows that consonance is a **goal** of information **processing**.

"4. Dissonance irritates, motivates, activates. It can lead toward consonance, or toward greater dissonance, involving antagonisms, aggression, **chaos** and destruction.

"5. Curiosity - the desire to know - is inherent in **assimilation**. Because information seeks **consistency**, mentation involves a continuous search for new information.

"6. The human mind... is inventive. It will create - even fabricate - **images**, explanations and **concepts**..." (1981, p.16).

HENSHAW also states that: "Information, like **energy**, exerts an influence" (p.17). However, while interesting, these ideas are somehow giving to "information" the character of a human actor.

1663

INFORMATION (Entropy and)¹⁾

As noted by S. UMPLEBY: "Information and thermodynamic entropy are different concepts. Only the equations are similar".

However, information and **entropy** are somehow in a polar **relationship**. A. RAPOPORT, for example, writes: "WIENER's insight into the meaning of the mathematical connection between **entropy** and information provides further clarification of the fundamental principles of the living **process**. Increase of **entropy** can be viewed as "destruction of information". Conversely information can be used to reduce **entropy**" (1966, p.6).

J.de ROSNAY explains in these words the antinomic relation between information and **entropy**: "Any information which results from an **observation**, a **measurement** or an experience, and says what we already know, does not produce any **change** in the number of possible answers. It does not reduce our **uncertainty**. The information provided by a **message** or an **event** is so much the greater that its probability of occurrence was small. The information obtained by sorting *on the first draw* the

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

correct answer (for example $I=32/1$, in the case of a pack of cards) is the inverse of the probability to obtain it as it was before receiving the **message** ($I=1/32$).

"Now, probability and **entropy** are connected by statistical theory.

"One notices by comparing the different mathematical relations, that information is the opposite of the physicist **entropy**. It is equivalent to an anti-**entropy**. This is why the term **negentropy** (which means negative **entropy**) has been coined, in order to emphasize this important property. Information and **negentropy** are thus equivalent to potential **energy**" (which may be used to produce or transmit information).

"However this comparison may be furthered. By conveniently selecting the constant and the unities, it becomes possible to express information by means of thermodynamical units, thus connecting it directly to **entropy**. In this way it is possible to calculate the smallest "fail" of **energy** associated to some measure capable to generate a **bit** of information: in order to obtain an information equal to a **bit**, a very small, but finite, and thus significant, quantity of the universe's **energy** must be degraded.

"This very important discovery led some physicists, like L. BRILLOUIN, to generalize in this way CARNOT's principle, in order to express the undissociable relation between information acquired by the **brain** and the **entropy** variation of the universe: Any acquisition of **knowledge**, obtained from an **observation** or a physical **measurement**, uses up **energy** from the laboratory, and thus from the universe" (1975, p.171-2).

This also true for information obtained by a **receiver** through some **channel**, which could transmit nothing without using **energy**.

1664

INFORMATION: Etymological clarification ^{1) - 3)}

Etymology is quite an interesting platform when we explore the meaning of "information".

A. ZELENKAR writes: "Form is the essential root in grasping the **meaning** of information...

"...the Greek "morfe" means **form**, shape, figure, body, grace, beauty... the latin "forma (-ae,f.) is figure, form, appearance (exterior), beauty, picture, **sign**, plan, base, contour, manner, way, kind, quality. The latin "formatio (-onis,f.)" is creation, formation, **representation** (**mapping**). The latin verb "formare" has the **meanings** to form, shape, picture, represent; to educate, instruct, teach; to control, settle, adjust, **regulate**, put in **order**, make do, create, produce, execute. The latin prefix "in" has spatial, temporal, and modal **meanings**. They are: about, after, against, as, at, behind, beyond, during, in, into, on, till, to, towards, until, up to, upon, within, etc.

"In grasping the notion of information one has to consider the Latin word "informatio", which is the composite of "in", "forma" and "tio". Here, the **meanings** of "in" and "forma", with all their diversities and combinations, have to be taken in account. **Meanings** of the Latin informatio are forming, putting into **form**, presentation, notion, description of notion, explanation, interpretation, etc... In scholasticism, this **meaning** is etymological and ontological: it represents shaping of **matter** by **form**, where shaping is thought as a **process** itself and as a result. It has the **meaning** of forming the mind as a consequence of a co-natural **object** of **cognition**. Later, DESCARTES introduced the **meaning** of forming the **consciousness** by the physical **structure** of **brain**, which is becoming evident as **perception**" (1988, p.187).

To inform should also mean, in some cases "put **form** into something". Sir d'Arcy W. THOMPSON wrote many years ago (1916) a marvelous book about "Growth and Form", in which extended studies of comparative **forms** in plants and animals lead the reader to the insight of the existence of what we could call "meta-forms". For us, humans, there is a rich information to be extracted of "nature's play with families of forms". But, of course, we are again lending significance and human motives to an abstract and projected entity invented by our brains: "Nature".

Even so, we are able to perceive numerous **forms**, to coordinate many of them in families and to extract from them a quite general **information**.

1665

INFORMATION (Evolution of) ¹⁾

S. GOONATILAKE proposed an evolutive hypothesis about information: "The **evolution** of information on earth gave rise to the sequence of information cores which emerged corresponding to these different environmental stages. In the first core, the struggles with the **environment** is coded in DNA. Later, outer flow cores are 'externalized' from this inner core of DNA, corresponding to the cultural **flow** lines running through **brains**. Still later, **exosomatic** information **flow** lines are externalized out from the biological package" (1991, p.132).

Moreover: "The different **flow** line cores do not exist unconnected and unattached to each other. They are inexorably linked... It is a continuing **process**, of reacting with and adapting to the **environment**. The tendency towards further elaboration and **evolution** of information is therefore but a necessary outcome of an almost inevitable phylogenetic **process**" (ibid).

The successive and progressive **forms** of information are thus embedded within each other. Curiously, this **process** seems to be accelerating through time, which parallels F. MEYER's theory of **evolutive acceleration**.

1666

INFORMATION (Generative) ^{1) - 2) - 3)}

A basic information **set** which is able to generate a specific type of **order** in a quite wider **space-time**.

The genetic **code** may be considered an example, and in a different setting, the **values** system of a **community** or culture. The concept is closely linked to D. BOHM and F.D. PEAT's "Generative order" (1987, p.195).

1667

INFORMATION (Irrelevant) ²⁾

"Information which operates on a subspace orthogonal to that specified by the question" (D. Mac KAY, 1969, p.74).

This somewhat abstract formulation means that any question specifies an area in which information is needed and any information not referred to that area has no practical value as a **response** to the question.

Mac KAY adds that irrelevant information "is clearly distinct from "semantic noise" which is any feature of a **message** that reduces the sharpness of the selective **operation** on the required subspace" (ibid) (i.e. within the specified area).

1668

INFORMATION (Positional) ^{1) - 5)}

Morphogenetic information potentially present in the specific spatial **interrelations** of some **elements** in an incipient system.

This notion emerged in the 1970s (L. WOLPERT) in the study of genetically based differentiation in living beings **organization**. Such differentiation corresponds to chemical **gradients**.

The relative positions of some genes (homeobox genes) "allows one **part** of the embryo to be labelled as different from all other **parts**... Such information is present even in the unfertilized egg **cell**... (where) there is already a "head" end and a "tail" end.

"The amount of positional information builds up during the development of the embryo. Eventually the positional information is so complex that very small groups of **cells**, destined to become a particular **part** of the body, can be distinguished" (S. DAY, 1990, p.4).

More generally, positional information is related to **symmetry-breaking**. G. NICOLIS and I. PRIGOGINE state: "Physiologically, the best known type of positional information is ensured by monotonic **gradients** of appropriate **morphogens** establishing a polarity within the **field**... A **gradient** (or more generally a primary spatial **pattern**) arising in this way should have some well defined reproducibility" (1978, p.26).

The notion of positional information looks like a good candidate as a general systemic concept; for the following reasons:

- it seems to be related to a universal concept of polarity
- it seems to be a bridge between **levels of autopoiesis**
- it connects both **meanings** of the concept of **morphogenesis**
- it makes sense in practically each **level of complexity** from crystals to human societies (**stigmergy**).

1669

INFORMATION (Potential)¹⁾⁽³⁾

As noted by D. GERNERT, information may exist in a potential form (or structural **form**) as for example in a crystal (2000, p. 255)

The use of two different terms – structural, potential- is very useful; for a better understanding of the nature of information.

A crystal is an ordered **structure**, would we say. But to say it in that way implies a **semantic ambiguity**. In fact the structure becomes apparent only to somebody who is able:

- 1) to observe it by sight or using an appropriate device
- 2) to make sense of what can be seen "Potential" information becomes effective only after passing through **perception** first, and interpretation next.

This becomes still clearer when we find out that deformations in our perception and spurious interpretation (i.e. that does not allow us to act efficiently on the base of our view) can lead us completely astray-even if structural information has not changed, i.e. is still there potentially within the crystal.

1670

INFORMATION (Pragmatic)¹⁾⁽³⁾

The impact of transmitted information upon the receiving system (Adapted from D. GERNERT, 2000, p. 254)

GERNERT adds "Information is anything that alters the **state** or the **behavior** of the receiving system"(Ibid)

It should be noted that information acquires **meaning** only when the **receiver** is a living being, specially a human being who is capable of very elaborate **understanding**, interpretation and subsequent **action**.

A barometer, for example, registers **changes** in atmospheric pressure. But it has a graduated face, because it can have a practical use only if a person is able to register a reading in a way that makes sense for he/she.

1671

INFORMATION (Quantitative)⁵⁾

"The minimum... number of **binary** steps by which the **representation** concerned may be selected from an ensemble of possible **representations**" (D. Mac KAY, 1969, p.80, as stated by SHANNON).

This minimum number is the $\log_2$ of the number of **representations** or **objects** included in the **set**.

Or the number of **bits** which is necessary and sufficient to diminish, up to some degree, or to totally suppress any **uncertainty** in the **knowledge** of some situation or system. See: "**Information (Amount of)**".

This is why it is sometimes expressed in terms of "**negative entropy**".

1672

INFORMATION (Selective content of)¹⁾

"A measure of the unforeseeableness of a **representation**" (D. Mac KAY, 1969, p.176).

Mac KAY states: "This is a relative measure, depending on the number of distinct results which are regarded as equally probable by the **observer**."

"The result observed is thought of as specifying one of a number of possibilities already contemplated by the **observer** as forming an ensemble in defined proportions" (p.174).

By "ensemble" Mac KAY means: "A **set** of possibilities, each of which has a defined probability" (p.175).

The concept is close to VENDRYES' one of "subjective probability": Probable (more or less so) is any **event** which did not yet occurred (or, from a different viewpoint, has not yet been observed).

Mac KAY still adds: "Selective information-**content** in fact measures not a stuff but a **relation**, and is not defined unless both terminals of the relation are specified" (p.77). See "Formation of **meanings**".

In a slightly different meaning, information is selective as it carries "**difference, distinction, order, constraint, pattern, etc...**" (G. ANDERSEN, 1995).

G. BATESON made a similar point when defining information as "Any difference that makes a difference" (1979, p.228)

1673

INFORMATION (Shared) in multiple agents systems^{1) - 5)}

J. ERCEAU and J. FERBER, who are researching **multiple agents systems** (wherein **communication** is paramount), write: "There exists presently two types of architecture for **communication** systems (i.e. in M.A.S.). One instates a **communication** procedure by shared information, and concerns basically advanced **agents**, namely cognitive ones. This procedure uses a common space (the "**black-board**"), centrally controlled on which every **agent** writes or reads informations. The other, used indifferently by cognitive or reactive **agents**, consists merely in exchanges of asynchronic and **discontinuous messages** from one agent to any other" (1991, p.754-5).

Such devices curiously mimic centralized or decentralized social **communications** systems.

1674

INFORMATION FLOWS²⁾

As noted by E. LASZLO: "Information flows through the system and connects the various **components** according to definite functional **patterns**. Each **component** receives information, processes it according to the tasks assigned to it, and produces more information which in turn is received by one or several other **components**" (1974, p.152).

The correct plotting of information flows in the system is one of the basic features of J. FORRESTER's **Systems Dynamics**. In a more general sense, any kind of **network** is closely depending on information flows.

Graphs are practical tools to trace and visualize information flows.

1675

INFORMATION FROM CONTEXT¹⁾⁽²⁾⁽³⁾

In the widest sense, we obtain all information from our **environment**, through our **interactions** with it. But the quantity of information that we are able to gather depends on our own mental (and psycho-motor) **frame of reference**. For example, a geologist observing a rocky mountain cliff would gather more information from some of the features he sees than a common **observer**, because he knows the implicit **meaning** of the sedimentary strata he observes. He thus becomes able to interpret what he sees and even register some specific and peculiar characteristics out of which he may develop a deeper **understanding**.

The point is neatly made by I. STEWART in a paper about magic. The magician is basically a trickster who uses **codings** and **rules**. specially if working with an aide. He becomes able to gather information from gestures or words that seem indifferent to spectators (2003, p. 38-39

→ **Code; Experimental frame; Frame of reference; Meaning (Formation of); Meaning theory; Observation process; Observer**

1676

INFORMATION HALF-LIFE^{1) - 4)}

"... the amount of **time** for half of the given informational **set** presently serving as a base for tying a society successfully to its **environment** to become useless" (T.R. YOUNG & G. SWARTZMAN, 1974, p.260).

The authors who introduced this somewhat metaphorical concept, (obviously by **analogy** with half-life of radioactive compounds) used it to construct the following "general principle of irreversible sociothermodynamics:... The short-

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

er the information half-life of a system, the shorter the turnaround **time** for information handling must be in order to maintain system integrity" (Ibid).

They add: "As the **rate of change** of a system or its **environment** increases, the half-life of the information stored in the system decreases. In a stable society (a society in a stable **environment**), the half-life of the information stored in traditions, myths, plays, and everyday wisdom is counted in the centuries and is sufficient to meet the ordinary contingencies of **decision-making**" (Ibid).

Elaborating on this **concept**, we may possibly distinguish:

- **data** half-life, as very short (but in any case longer for global **long-term data**);
- information half-life, as short to medium, according to the type of information;
- **values** and **norms** half-life, as long to very long
- wisdom and art half-life, as very long and even possibly limitless.

If the physical analogy may be pushed farther, the degradation of information should be **asymptotic** and possibly, it would never become totally extinct.

1677

INFORMATION: Implicit or Explicit ¹⁾³⁾

A frequent semantic muddle results of the use of the term "information" as applied to the postulated information **content** of, for example, the geological strata, or a crystal, or the genome.

None had any information value until their existence was discovered in the first place and thereafter progressively interpreted within some slowly constructed and evolving scientific theory (i.e., **frame of reference**)

Curiously enough, we can now agree that the "genetic code", for example, contains "information" only after giving it at least the beginnings of an explicit **meaning**.

Thus, any hypothesis about implicit information can emerge only after the initial formulation of some more or less verifiable explicit meaning applied to some entity that must be clearly identified (another construction of meaning), to begin with.

For more, see the following entry

1678

"INFORMATION" in non-human natural systems ^{1) - 3)}

The use of the term and *concept* of "information" outside of **human systems** should be at least seriously questioned.

It is, for example, sometimes stated that the DNA "contains coded genetic information". It is thus implied that the **cells** receive "**messages**" containing some "**meanings**" which influence their **behavior**, because they are able to "understand" these "**meanings**".

All of this vocabulary really reflects a deep-seated anthropomorphism. We translate and "psychologize" cellular **behavior**, using quite an over-extended **metaphor** if we remember that "informatio" is some exchange between **brains**, or, at most, between a **brain** and a computer.

However, DNA effectively "rules", at least, part of the **cell behavior**. Is thus information somehow equivalent with **behavior control**? And dare we concede a kind of volitive **action** to DNA over the **cell**? We may allow ourselves the right to use **isomorphies**, **analogies**, and even **metaphors**, but we should be careful and avoid **semantic** abuse.

1679

INFORMATION: its material media ^{1) - 5)}

J.M. RODRIGUEZ DELGADO points out the necessity to avoid confusing **information** with the various types of **media** used to transmit it: "... paper and ink can be used as **media** to carry non specific **messages** of quite different significations" (1992, p.162). He adds: "... the **functions** carrying **messages** must be distinguished... from mental manifestations. Thus, for example, the eyes and the optical nerves are needed in order to see, but they work only as non specific carriers and **transducers** of visual **forms**, which are in effect recognized by the occipital lobe and other cerebral regions" (Ibid).

In the same way, an electromagnetic wave may carry visual or auditive **messages** of very numerous different types, which can, or not, be decoded by a given **receptor**. To understand a **message** in Russian, one needs to know Russian, and not merely to hear correctly the sounds or see the cyrillic characters.

It is thus obvious that the **understanding** of information is not merely a matter of registering the medium, but requires the **learning** of the specific **codes**.

1680

INFORMATION, KNOWLEDGE and UNDERSTANDING ³⁾

R. ACKOFF and J. GHARAJEDAGHI (as quoted by M. DODDS & G. JAROS, 1994) "identify three **levels** in the **hierarchy** of **knowledge**:

"Information is descriptive: it is contained in answers to questions that begin with such words as What, Which, Who, How many, When and Where. **Knowledge** is instructive: it is conveyed by answers to How-To questions. **Understanding** is explanatory: it is transmitted by answers to Why questions..." DODDS & JAROS

add "Understanding presupposes knowledge and information. Information presupposes neither knowledge nor understanding. It does presuppose a perspective and the **purpose** of an inquiring viewer, for it is information for someone. To the above **hierarchy** one could add wisdom, as the knowledge of what to do in any given **context** of problems".

More carefully still, what is factually possible to do should be distinguished from what is socially, and ethically suitable to do.

1681

INFORMATION MATRIX ²⁾

A matrix in which the structural and metric information **content** of a system of **interrelations** is specified.

This **model** has been introduced by D. Mac KAY, who proposes to represent the **metron-contents** of **logons** as the **elements** of a diagonal information matrix" (1969, p.170). He writes, for instance: "The intended **meaning** of the **communication** is... definable as the **selection function** that is intended to exercise on the **range** of possible **states**" (1972, p.28).

This is to be related to STEINBUCH's **learning matrixes**.

1682

INFORMATION MEASUREMENT ²⁾

J.de ROSNAY explains with great clarity what is meant by information measurement, why and how to measure it and how the concept of information quantity is totally independent of its **meaning** (and is purely technical):

"In order to define conveniently what a certain quantity of information represents, one must place oneself in the situation of an **observer** seeking information about some ill-known system. It may be for example the number of possible answers to a question; or the number of solutions of a problem.

"Obtaining informations on the unknown system may lead the **observer** to reduce the number of possible answers. A total information could even lead immediately to only one possible answer: the good one. Information is thus a **function** of the relation between the number of possible answers before the **reception** of the message (P_0) and the number of remaining possible answers after **reception** (P_1)

"A very simple example: the unknown system is a pack of 32 cards. Question: what is the chance to select some predefined card?

"This question introduces an **uncertainty**, which can be metted by a relation; i.e. the number of favorable cases respect to the number of possible ones (which means: the probability to sort out the good card) As there is only one favorable case (the chosen card), this probability is of one chance in 32.

"Now, how to meet the quantity of information obtained by sorting one card? Before sorting it, there are 32 possible cases with the same probability (P_0). After sorting it, two different situations may appear:

"Either the good card was sorted. In this case, there is only one possible answer (the one in hand). The quantity of information thus obtained corresponds to the relation $32/1$, and the information is total.

"Or a useless card was sorted and there are still 31 possible answers. The quantity of information now obtained corresponds to the relation $32/31$. The information is partial.

"The information obtained in the first **situation** solves definitively the problem by reducing to 1 the number of possible cases. In the second, the number of possible cases is only slowly reduced. It thus reduces the denominator of the relation P_0/P_1 : the relation increases and the information too. This is to say that information increases when **uncertainty** decreases. This is because **uncertainty** expresses the lack of information about the unknown system.

"Finally, to meet information and to define unities, two conventions are made: information is preferentially defined in a subtractive way, better than by a relation, as information is the difference between two **uncertainties** (before and after the **message**). We substitute thus to the relation P_0/P_1 a difference of their logarithms. The second convention: as the most practical and used **code** to translate a **message** is made of two **signs**: 0 and 1, the **binary language** and the base 2 logarithms will be adopted. When using these convention, the quantity of information in a **message** is meted in **bits** (i.e. binary digits)...

"Information (quantitative) appears thus as an abstract entity, objective and devoid of any human **significance**. It is easier to understand what is a quantity of information by assimilating it to material units circulating in some **channel**: for example as water molecules in a pipe. The **flow** in the pipe is limited by its section. It is just the same for any transmitting line... as for example a telephone wire. This quantity of information is totally independent of the **significance** of the **message**: a song, the results of the horse races or the market's quotations" (1975, p.170-71).

From a different viewpoint I. PRIGOGINE and I. STENGERS state: "We may use the algorithmic theory of information proposed by CHAITIN and KOLMOGOROV: The measure of information should be the length of the **program** that would have to be given to a computer... in order to make it able to achieve the **structure** that we wish (to obtain)" (1992, p.83). Even in this case however, information is still related to an **observer**.

1683

INFORMATION, Nervous System and Brain³⁾ - 5)

Information remains potential until it is received and organized by a **brain** (in its own **auto-poietic** way), computer or any other electronic means. These latter ones acquire **meaning** by making a **difference** ... but only when reaching a **brain**.

J.J. GIBSON criticizes the pure **communication theory** of information: "The information that can be extracted from ambient light is not the kind of information that is transmitted over a **channel**. There is no **sender** outside the head and no **receiver** inside the head".

At least, there is no specific transmitting device "out there". The real world does not transmit **messages**, even if electromagnetic **waves** ramble all around us. "The world does not speak to the **observer**... Words and pictures convey information, carry it or transmit it, but the information in the sea of **energy** around each of us; luminous or mechanical or chemical **energy**, is not conveyed, it is simply there" (1986, p.242). In von FOERSTER's words: "The world is as it is" ... and that's all". As to what is inside the head, it is much more than a receiving device, even if the senses are specialized as pick up devices. We could do nothing with collected sensorial **data** if our **brain** were not **organized** to "**understand**" them, that is interpret them in relation to its acquired internal **order**, i.e. its **organizational closure**, in **auto-poietic** terms.

GIBSON's reaction against pure **mechanicist cybernetics** is anyhow understandable and quite common to many psychologists and sociologists. But his problem seems to be more **semantic** than anything else: Our senses do not collect information, nor even **perceptions**; they collect sensations. Accordingly a sentence like: "**Direct perception** is the **activity** of getting information from the ambient array of light" (p.147), is ambiguous.

→ **Knowledge (Tacit)**

More recently, A. ZELEZNIKAR still reflects somehow the **mechanicist** view and describes accordingly the nervous system and the **brain** as **receivers**, **processors** and **emissors** of information. (After all, there is something therein!)

"**Brain** is a living substance and **behavior** is a living **processing**. **Brain** is the commanding apparatus of a being's **behavior**. **Brain** is a sort of information **machine**, which enables and handles information **processes** of **behavior**. The brain also influences and in some way structurally and organizationally limits **behavior**, and **behavior** has similar developmental and **generative** influence on these **functions** (informational **processes**) which frame the so-

called mind. **Brain** and **behavior** are particular examples of information **forms** and information **processes**.

"**Brain** consists of basic informational units which are the neurons and the glia **cells**. These basic units govern the most elaborate **cognitive functions** (**behavioral processes**). The functioning of neurons in the **brain** is influenced by the **behavior**, which comes as a consequence of sensory information from other beings as well as from other environmental **phenomena**. However, groups of neurons are structured (functionally connected) within the nervous system into regional **subsystems** (regions, areas, nuclei), so that behavioral **processes** can be localized in specific areas of the **brain**. Regions of the **brain** are specialized for many different **processes**, which constitute particular behavioral information - mental and motorial. The central nervous system is a bilateral and essentially symmetrical information machinery, which consists of the following main **parts**:

"1. The spinal cord receives information from the skin, joints, and muscles of the trunk and limbs, and sends out motor information for the reflex movement and voluntary movement.

"2. The medulla oblongata is the supreme extension of the spinal cord and incorporates, in addition to other nuclei, reflex nuclei for breathing, functioning of heart, coughing, vomiting, etc.

"3. The pons and the cerebellum are supreme to the medulla. The cerebellum is modulating the force and range of movement.

"4. The midbrain is supreme to the pons and lies between hindbrain (the medulla, pons and cerebellum) and the forebrain (the diencephalon and cerebral cortex)

"5. The diencephalon contains two informational relay **structures**. The thalamus processes most of the information coming from the rest of the central nervous system to the cerebral cortex. The hypothalamus controls autonomic, endocrine, and visceral **integration**.

"6. The cerebral hemispheres consist of the basal ganglia and the overlying cerebral cortex. Both the cortex and the basal ganglia are concerned with higher perceptual, cognitive and motor information

"The medulla, pons, and midbrain constitute the **brain stem** which contains cranial nerve nuclei which in turn receive information from the skin and muscles of the head and from the special senses of hearing, balance, and taste. Other nuclei regulate **motor output** information to the muscles of the face, neck and eyes. The **brain stem** incorporates another **structure** called the reticular formation, which determines levels of arousal and awareness.

"Another structural and organizational principle of the **brain** is **parallel** (information) **proc-**

¹⁾general information

²⁾methodology or model

³⁾epistemology, ontology and semantics

⁴⁾human sciences

⁵⁾discipline oriented

essing. Brain processes are served by more than one pathway. Within the **brain**, the cortex is divided into two hemispheres with four anatomically distinct and functionally specialized lobes: the frontal, parietal, occipital, and temporal. In these lobes, planning and movement, somatic sensation, vision and audition as well as **learning, memory** and emotion are processed respectively. Each hemisphere of the cerebral cortex is concerned with sensory and motor **processes** of the contralateral side of the body. The hemispheres are not symmetrical in **structure**, nor are they equivalent in **function** (information **processing**). For example the **cognitive** aspects of **language processing** are localized in Wernicke's area and in Broca's area in the left hemisphere. However, affective components of **language** as the musical intonation of speech, emotional gesturing, prosodic comprehension, and comprehension of emotional gesturing are **processes** in the right hemisphere, where their anatomical **organization** mirrors that which is for cognitive **language** in the left hemisphere.

"Even though, the **brain** is immensely complex and the **structure** and the **function** of many of its **parts** are still poorly understood, it is becoming more and more evident that it is an informationally structured and informationally organized apparatus with specific **processes** occurring in its **parts**. These **processes** – the mind – is an informational **function** which is becoming more and more understandable in modern neural science and in **informatics**" (1988, p.210-12).

Summarizing and complementing, the **brain**:

- is endowed with a complex anatomical and physiological **organization** which is improved by **learning**, which may grant it a wide **variety**;
- is endowed with a huge potential capacity for **processing** information (however this capacity remains limited);
- works in a **parallel** way, which limits the **deterministic** character of its **activity** and endows it with a certain **randomness**, which is probably the origin of **creativity**.

→ **Brain**

1684

INFORMATION OVERLOAD ¹⁾ – 4)

Any **input** of **data** which exceeds the **integration** and interpretation capability of a human **brain**.

While **communication** overload occurs in **transmission systems** as for example telephone **nets** or streets, information overload is a material (see R. WURMAN, 1989), but also, according to W. REEVES, a psycho-social **phenomenon**. Everywhere: "...the multiplicity of papers, periodicals, mail, notes, memos and

videos ... inundates our daily lives and numbs our critical thinking **processes**" (1992).

It occurs, writes K. DEUTSCH "within the minds and nervous systems of people..." and "The wider the **range** of relevant **choices** we put before a person of limited physical and psychic **resources** and capabilities, the more acute and pressing we make his problem of economy in allocating his own **time**, attention and **resources**" (1961, p.96).

Information overload is rapidly becoming a critical issue, because it interferes with the **management of complexity** (of which it is an important aspect in itself). REEVES contends "that the information explosion is a tremendous obscuring force for the the **cognitive process** within our society" (1992, p.95).

As an antidote for information overload in **situations** where the **flow** of information exceeds **processing** capacity, J. WARFIELD proposes his law of **requisite parsimony**.

→ "Christmas tree effect"

1685

INFORMATION SPACE ¹⁾³⁾

A set of "elementary **semantically** meaningful statements (or interpretable structures) together with specific relations between these **elements**" (D. GERNERT, 2000, p. 253)

GERNERT observes (like in different terms McKAY before him) that "the so-called "information theory" created mainly by SHANNON and WEAVER, was originally intended as a theory of **information transmission**. The floppy and misleading terms "**theory of information**" and "**information theory**" emerged only later and do not at all reflect the real capacities of that theory. SHANNON himself advanced a passionate pleading against the overestimation of the theory essentially originated by himself" (Ibid.)

GERNERT's definition contains terms like "semantically meaningful" and "interpretable" that clearly show that any "**information space**" is shaped by what could be called "**meaning creators**", who construct through **conversation** a common **code** of meaning. This is the real prerequisite for any explicit information.

The common code has at least two **levels**. The first is a shared **language**, as for example English, or French.

Thereafter, and within the selected language, more specific codes can be constructed as for ex. the basic definitions of **topology** or MENDELEEV's table in chemistry.

Of course, these last codes can be expressed in any spoken or written language (more or less easily)

However, any information space can become distorted, and particularly so the **fuzzy** and un-

stable **set** of terms related to human sciences and **beliefs**. The numerous interpretations given to terms like "democracy", "freedom", "development", "unconscious", etc., clearly show the unreliable character of these kinds of "information".

GERNERT also observes that in an information space: "both the elements and the **relations** may vary in the course of time"

In fact, any instantaneous "snapshot" of the set is a provisional structural state of the information space.

"**Time**" is introducing a **dynamics**, i.e. produces a series of transformed such structural states.

GERNERT states moreover: "The mathematical structure of an information space, which is given by the relations existing between the elements, may also depend on the interpretant, and furthermore, vary with time" (Ibid)

GERNERT proceeds next by developing that mathematical structure along the concepts of **links, clusters** and **similarity metrics**.

→ **Grammar-Infon-Logon- Metron**

1686

INFORMATION SPACE (Mathematics of) ²⁾

D. GERNERT tries to give a precise mathematical meaning to information space.

He quotes SNEDDON's general definition of space in his "Encyclopedic Dictionary of Mathematics": "The term space is used in mathematics for any **set** when certain types of properties are to be discussed or when it is intended to use some sort of geometrical terminology" (2000, p. 255)

Therefrom GERNERT defines "...an **information space** by a set consisting of **elements** (of a special kind), together with possible **relations** between these elements, both the elements and the relations may vary in the course of time".

"An element is understood as an irreducible unit which still carries some **semantic contents** and particularly has the character of a statement or proposition - no matter whether... - **bits, bytes**, characters, words, pixels, or other small **parts** whatsoever" (Ibid).

Further on, GERNERT describes the mathematical **structure** of the information space, which includes:

- standard and non standard **links**
- **cluster** structure
- **similarity** metrics (internal and external)
- emerging structures in dynamical **processes**

Interestingly, GERNERT states in his concluding remarks that "Information spaces in the sense outlined... can be easily modeled on an ordinary PC" (Ibid, p. 261)

1687

INFORMATION STORAGE²⁾

Natural systems store information naturally.

While the notion of information is a creation of the human **brain**, to speak of information in biological systems, in **ecosystems**, and even possibly in a quite **metaphorical** sense in physical systems seems however reasonable.

Animals and vegetals somehow **communicate**. This is also the case of **cells** in **organisms**, and even among chemical molecules.

Now, to communicate information, in whatever way, they must have it permanently available, i.e. they must have it "in store".

Information storage remains however one of the most elusive **processes** in natural systems, as to how it is done and as under which **forms**.

1688

INFORMATION (Structural)²⁾

"The number of independently variable features or **degrees of freedom** of a **representation**" (D. Mac KAY, 1969, p.176).

Mac KAY states: "Structural information is not concerned with the number of **elements** in a **pattern**, but with the possibility of distinguishing between them" (p.165).

In Mac KAY's terminology (in this case adopted from GABOR), structural information is made of units, named **logons**.

Similarly, M. MARUYAMA states: "Information is **specificity**, structuredness and improbability" (1994, p.83).

1689

INFORMATION SYSTEMS DISCIPLINE¹⁾

J.van GIGCH distinguishes the following schools of thought in this discipline (1993, p.46):

1. Sciences of the artificial
2. Systems Sciences or Sciences of **Complexity**.
3. **Decision Sciences**.
4. **Cognitive Sciences**.
5. **Computation Sciences**.
6. **Communication Sciences**.
7. **Control Sciences (Cybernetics)**.
8. Computer Sciences and **Artificial Intelligence**.
9. **Complex Systems Engineering Sciences**.
10. Complex Social **Organization Sciences** and **Management Decision Sciences**.
11. Normative **Decision Theories**.
12. **Management Theories**.
13. **Operations Research and Management Science**.
14. Social **Communication and Behavior Theory**."

Cybernetics does not only contribute to **control sciences**, but also to social **communication** and psychology, as shown by von FOERSTER's **2nd order cybernetics**.

In his paper, van GIGCH contributes an interesting table (by himself and J.L.LE MOIGNE) about "**Purposes and metaphors** of the disciplines which contribute to the **design** of an information system" (p.47).

A very different **viewpoint** is G. PATON's one. In a 1997 paper he observed that "Information system" as an expression is quite ambiguous, as "words in any **language** are overloaded with several distinct **meanings**". The problem started with Shannon's use of the word "information" in his foundational paper on "mathematical communication theory"(1948), even if he cannot be made responsible for the generalized error of later authors to refer themselves to SHANNON's theory of "information".

PATON states clearly that information is "a particular parcel of **knowledge**, acquired at a particular moment in time"(p. 69), irrespective of course to the fact that the "informed" person communicates that information to another person.

This is different from MacKAY's wording about "**logon**" (i.e. coded meaning in a linguistic and **semantic** sense) and "metron" (i.e. coding of such logon in a communication code, electronic, or whatever). However, it helps to combine MacKay's approach to Paton's one.

As to "information systems"another **ambiguity** emerges. PATON observes: "if you think of information as existing out there in the world"(in a **computer** for ex.) ..."you are working with information as a **resource**, just like finance. All the dangers of the take-over by accountants now apply to take-over by I.S. managers"(Ibid, p. 70)

And of course, IS managers become **controllers** aiming at making a profit by installing suitable valves within the communication **channels** (and eventually also installing censure or manipulation)

Accordingly, PATON considers that "information systems", before becoming a "resource", are "intellectual **constructs**"(p. 71). As such, they are open systems, very different of the boxed products that become protected commercial items, as for example patents, software packages or any other finished product.

1690

INFORMATION: the autopoietic view¹⁾³⁾

S. BRIER writes: "The system does not receive objective information from outside as a **stimulus** to which it responds. Instead its **organization** is perturbed by some things happening in the surroundings and its "answer" is an internal **adjustment** to maintain its organization. It is reacting to its own internal **network**. Information therefore is not something outside, but rather is a **phenomenon** created inside the **organism**"(1995, p. 7)

This is Maturana's version. QVORTRUP observes that his theory is "somewhat **solipsistic**"(1993)

Of course, human beings are unavoidably "somewhat" solipsistic. It must be the only condition for maintaining **identity** within a **range** of adaptive **change**

1691

INFORMATION THEORY^{1) - 3)}

Under the general wording of Information theory widely different subjects have been considered:

- 1- A theory of **transmission** of information through a physical **channel**, which is in reality a **theory of communication** (in the physical sense).
- 2- A quantitative theory of information, which considers for example the quantity of **bits** necessary to convey some information.
- 3- A theory of **meanings**, which looks into the transfer of significant information from a **semantically** able **emissor** to an equally **semantically** able **receiver** (or many).

D. Mac KAY expresses this idea: "Information theory is concerned with the making of **representations**, i. e. **symbolism** in the most general sense" (1972, p.161).

According to Mac KAY: "General information theory is concerned with the problem of measuring **changes** in **knowledge**. Its key is the fact that we can *represent* what we know by means of pictures, logical statements, **symbolic models**, or what you will. When we receive information, it causes a **change** in the **symbolic** picture, or *representation* that we could use to depict what we know" (p.42).

Still in Mac KAY's words: "The scope of information theory thus includes in principle at least three classes of **activity**: 1) Making a **representation** of some physical aspect of experience. This is the problem treated in *scientific* or *descriptive* information theory;

- 2) Making a **representation** of some non-physical (mental or ideational) aspect of **experience**. This is at the moment outside our concern, being the problem of the Arts;
- 3) Making a **representation** in one **space B**, of a **representation** already present in another **space A**. This is the problem of **communication theory**, B being termed the receiving end and A the transmitting end or a **communication channel**" (p.162).

Thus, at least in the realm of **symbolic coding**, **communication theory** is included within information theory.

However, a serious confusion besets the whole subject. For example, Mac KAY writes: "SHANNON wisely insisted that the **concept** of "meaning" was outside the scope of his theory"

"This innocent statement by SHANNON has given rise to two unfortunate consequences:

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

"In the first place the original sense of SHANNON's warning has sometimes been forgotten and he is credited with the view that the whole theory of information (which includes his own theory of the unexpectedness of information as a vital part) has nothing to do with "meaning".

"Secondly, and largely in consequence of this, the idea has become current that the whole subject of **meaning** is not satisfactory for the information theorist. "Subjective", "vague", "dangerous", are the adjectives with which it is often smothered" (p.80).

From a different angle, M. MARUYAMA has observed that SHANNON's Information theory: "... was trapped in a classification **epistemology** which sees a **structure** as consisting of **elements** which tend to behave independently. In SHANNON's theory, the most probable or "natural" **state** of a system is that in which each **element** flips its own coin regardless of the other **elements**. The amount of information which a **structure** conveys is defined as the degree of departure of the **structure** from such probable **states** of nonstructure. The higher the improbability of the **structure**, the higher the amount of information. In this **epistemology**, **structures** tend to decay to more probable nonstructures" (1976, p.201).

In synthesis, SHANNON's Information theory is somewhat at odds with the systemic **viewpoint**: a bag of loose flipping **elements** is not a significant **network**, and still less a system.

The confusion about the real meaning of "information" in SHANNON and WEAVER remains deeply ingrained.

D. GERNERT still felt in year 2000 the need to write the following:

"The so-called "information theory", created mainly by SHANNON and WEAVER, was originally intended as a theory of information transmission. the floppy and misleading terms "theory of information" and "information theory" emerged only later and do not at all reflect the real capacities of that theory. SHANNON himself advanced a passionate pleading against the overestimation of the theory essentially originated by himself.

More and more- albeit still reluctantly- the idea is gaining broader acceptance that a theory of information which really deserves the name must also account for the **semantic** and **pragmatic** aspects of information" (2000 b, p.253)

1692

INFORMATION THEORY (Relativistic) ^{2) - 4)}

A theory about the nature of information, taking in account the "multiplicity of informative referentials" (adapted from G. JUMARIE, 1980, p.83).

JUMARIE writes as a conclusion to his enquiry: "A fundamental triplet seems to be essential for the definition of the concept of information, i.e.: the system S, material support of

that which is significant; UD, the universe of discourse that contains what is meant; and the individual **observer** R who interpretes it all in his personal subjective referential" (p.82).

S is the observed **universe**, and R is the observing system. Between both there is a **feedback cycle**, formerly well explained by R. VALLÉE through his **epistemo-praxeological loop**.

There are of course many R's who, together, generate by **consensus** a **universe** of discourse UD, by comparing their different **experiences** of the observed Ss. This is a **semantic universe** whose roots are socio-cultural.

The general result is the relativity of **information**.

1693

INFORMATION TIGHTNESS ¹⁾

Invariance in time of the properties of a system (adapted from W.R. ASHBY, 1958, p.202).

When a **protocol of observations** contains **redundancies** and thus allows for statistical reduction (compactation in ASHBY's vocabulary – or the somewhat different **compression** in CHAITIN's sense) something may be stated about the **behavior** of the system only if its properties observed through the **protocol** are "not subject to unpredictable vagaries" (Ibid), i.e. "information-tight", at least so far as these properties are concerned" (Ibid).

The concept seems somehow related to MATURANA and VARELA's **organizational closure**, and may even have been one of its sources.

1694

INFORMATION TRANSFER (Some elemental structures of) ²⁾

Even very simple **graphs** show how varied are the modes of information transfer in a **net** of very few **elements**, as shown in some **graphs** hereafter reproduced from a paper by M. KOCHEN (1957, p.37)

see figure associated to entry 3247

M. KOCHEN gives 21 theorems related to organized **structures**.

1695

INFORMATION TRANSMISSION ²⁾

It is now evident that information is a very pervasive feature of all kind of systems, under widely different forms as for example genetic, ecological, organizational or cultural.

Its transmission takes place in various ways: physical, biochemical, demographic pressures, through gesture, **languages**, etc.

One of the most interesting is by reciprocal **perception** as in fish schools, or among ants or bees. Another is through the observation of formerly constructed **structures** (**stigmergy**).

It even now seems that in human societies, information through electronic devices is becoming *kind of autonomous* as observed by S. GOONATILAKE: "... because of the internal **dynamics** of the expanding **exosomatic** system, new **flow** lines will develop organically, radiating themselves into new **niches** ... **artificial intelligence** devices will give rise to novel solutions which eventually will lead to new **flow** lines" (1991, p.120).

1696

INFORMATIONAL SUBSTANCES ¹⁾⁵⁾

Stafford BEER emphasizes the importance of Candice PERT discovery that peptides acting as opiate **receptors** are present all over the body (Molecules of emotions" _ (1999, p. 452-54)

He argues that this discovery of what he calls "informational substances" leads to the unification or at least the bridging between neuroscience, endocrinology and immunology.

In the words of C. PERT herself: "The way in which peptides circulate through the body, founding their target **receptors** in **regions** far more distant than had ever previously been thought possible, made the **brain communication** system resemble the endocrine system, whose hormones can travel the length and breadth of our bodies: the brain is like a bag of hormones!" (as quoted by S. BEER)

1697

INFORMATION-POWER Hypothesis ¹⁾

"In systems which survive, the **component** with the most relevant **information** available to its **decider** is the one most likely to exercise power over or elicit compliance from other **components** in the system" (J.G. MILLER, 1978, p.100).

MILLER, gives the following example: "Some researchers have shown that, in small **groups**, the member who receives the most information is most likely to be chosen leader" (Ibid).

In biological systems, it seems that the hypothesis applies to the **brain**.

1698

INFRASTRUCTURE ¹⁾

The **set** of basic **structures** needed for the existence and **development** of a system.

This is basically an economic and social concept proper to **human systems**, which are constantly evolving and creating new **functions** and **structures**. Many of these are not basic to the **survival** and good **performance** of the system. Some may even reflect harmful developments.

1699

INGESTOR ²⁾

"The **subsystem** that brings **matter-energy** across the system **boundary** from the **environment**" (J.G. MILLER, 1978, p.3).

This is one of the 20 **critical subsystems** in J.G. MILLER's general taxonomy of **Living Systems**

1700

INHERITANCE OF ACQUIRED CHARACTERISTICS ^{1) - 4)}

The famous controversy about Lamarckian inheritance of acquired characteristics has never been definitively settled.

We need an explanation about the: "... **process** whereby the newer inventions of adaptive **behavior** are sunk deeper into the biological system of the **organism**", as stated by G. BATESON. (1973, p.225)
→ ("**Archetype**").

In cultural systems among humans (and possibly among some social superior animals) the **model** of **transmission** of **knowledge** and **behaviors** from one generation to the following through **imprinting, training and learning** (KORZYBSKI's **time binding**) seems to be satisfactory. It is even possible that this **phenomenon** inspired the very Lamarckian concept.

On the other hand, no convincing **mechanism** of inheritance of phenotypically acquired biological characters, other than genetic mutations, has yet been found.

Observations of social animals seems to indicate that only individually acquired **information** can be transmitted, by imitation, or **learning**.

1701

INHIBITING EFFECTS ^{1) - 2)}

The negative effects on **efficiency** or **growth** of **elements**, **populations**, or **subsystems** due to excessive closeness or **overcrowding**.

Any **element** or **subsystem** needs a sufficient **space** for its correct functioning. Furthermore, it benefits from **heterogeneity**, because it diminishes unfavorable **competition** between **elements** of the same type when they are sufficiently spaced. In M. MARUYAMA words: "You would not build two post offices next to each other" (1994, p.80).

Spacing is thus useful, as it contributes to avoid inhibiting effects.

Another and more subtle type of inhibiting effects which has been discovered recently is the killing by a parasite fungus of the roots of the black cherry tree of saplings of the tree growing within about 15 meters of the adult one.

As the saplings of other trees are not affected, this amounts to a ecological **dispersion mechanism**

1702

INHIBITION ¹⁾

A **constraint** strong enough to block a **process**.

The inhibitor blocks the **process** by substituting itself to some **element** crucial to the **process**.

In many cases the inhibition process is coupled with an **excitation** process. Their alternance allows the system to maintain itself in a restricted **range** of **stability** conditions. Excessive or too frequent excitation in some **critical** process may destroy the system, if not compensated in due time.

In many chemical and enzymatic reactions the inhibitor is more strongly reactive than the normal **substrate** which feeds the **reaction**. In some cases inhibition is irreversible, i.e. when the newly created bond is so strong that it cannot anymore be broken, or when the **substrate** is overwhelmed. In other cases however, inhibition remains reversible.

The concept seems useful at least if used carefully, as a heuristic **metaphor** in psychology, economics and possibly in **ecology** and social sciences.

A recent example could be the disappearance of cod's reproductive capacity under the pressure of overfishing on the Grand Banks of Newfoundland and its possible irreversible replacement by other species in its former **niche**. This type of **phenomena** in ecosystems is well documented.

→ **Catalysis; Constraint; Far-from-equilibrium condition; Instability; Oscillators; Periodicity; Stability (Poly-)**

1703

INHIBITION (Cross) ²⁾⁵⁾

A mechanism of mutual negative **association** between antagonistic **elements** or **subsystems**.

Cross inhibitions are frequent in biological, ecological or economic **processes**.

They are based on combinations of **positive** and **negative feedbacks** and are needed to maintain a regulated process within defined or pre-determined **limits**.

J. HOLLAND describes for ex. cross inhibition in **cells** associations and in chromosomal alleles (1992, p.60-64).

1704

INITIAL CONDITIONS (Sensibility to) ^{1) - 2) - 5)}

A condition in a **nonlinear** system by which very slight differences in initial conditions lead to considerable ones in the later **behavior** of the system.

More than one century ago, H. POINCARÉ, in his study "On the **three bodies problem** and the equations of dynamics" (1889), showed the impossibility to determine in an absolutely rigorous way the future positions of three (or N) interacting bodies: the problem cannot be satisfactorily integrated.

The basic cause of such a situation is that a 3-bodies (or more) system is not **deterministic** in a **linear** way.

N. PEGUIRON writes on this topic: "This sensibility to initial conditions, characteristic to any **long term deterministic prediction**, showed by POINCARÉ, is a general case in classical mechanics: only some quite simple cases escape to this, as for example the two-bodies system" (1989, p. 11).

In more complex cases, the discrepancies, not being still important, may remain unheeded during more or less a long **time**. This is what allows for example for apparently rigorous **prediction** of the astronomical **trajectories**. However, at long or very **long term**, it has been recently demonstrated that even the solar system is not absolutely stable.

PEGUIRON comments this situation in the following way: "**Indeterminism** in classical mechanics does not appears in their governing equations, but through the impossibility to apply them to a system not devoid of external influences. Clearly, in this case, the isolation **process** displays a property, (rigorous) **determinism**, which is not proper of real systems" (p.11).

The sensibility to initial conditions leads to **chaotic behavior**, i.e. to **unpredictability**, which grows with **time**. However this does not imply the total disappearance of **global determinism**.

POINCARÉ established the bases for the study of **deterministic chaos**, when he created the concepts of **limit cycle**, transverse arc and section normal to the **trajectory**, now called "**POINCARÉ's section**".

The non-instantaneous **transmission** of local causes and the **non-simultaneity** of the resulting **effects** makes up another way to account for partial and local breaches of **determinism** and of the unpredictable character of the **trajectories bifurcations**.

→ **Sensibility to initial conditions**

1705

INLET ^{1) - 4)}

A **channel** or pocket within a system or **subsystem**.

An inlet corresponds to the penetration of part of the **environment** within the system. It is however more of a kind of internal extension of the **boundary**. In some sense, the whole of the digestive or the respiratory tract for example,

could be considered as inlets, since their exchanges with the system proper take place only locally and through specific **input** (or **output**) **transducers**.

Inlets may end up as inclusions if the **connection** with the **environment** is completely severed. Such inclusions are generally, but not always, assimilated or eliminated after some **time**.

Social, economic and cultural **analogies** could be explored, as for example, foreign commercial communities within some nations or empires: Venetian or Genovese establishments within the Byzantine Empire was possibly a case.

→ **Frozen core**

1706

INPUT^{1) - 2)}

Any **matter**, **energy** or **information** that a system or a **subsystem** receives from its **environment**.

K. BERRIEN proposed to distinguish between **maintenance** inputs: "those which energize the system and make it ready to function", (i.e. **energy** and **matter**) and **signal** inputs: "those which provide the system with **information** to be processed" (1968, p.25).

Any input is obtained from a specific **source**, which should be identified as precisely as possible in order to establish the absolute or relative **dependence** of the system in relation to it. It is very important to know the degree of probability that the **source** will be able to produce the required input in quantity as well in quality during the whole span of **time** that the system will need it.

This implies a study of the **rate** of production of the input, of the possible **perturbations** that could affect it, and of **competition** from other systems to secure their own needs.

As some inputs may be dangerous for the system, it is also necessary to detect these, in order to avoid them. It should be noted that many systems receive a **variety** of inputs while being unaware of it; as for example our absorbing numerous pollutants which cannot be directly perceived by our senses.

Inputs must cross **boundaries** or **interfaces**. The way they do it in **space** and **time** is also a very important feature of the **interrelation** between the system and its **environment**.

Last but not least, the **transformations** of the input within the system are of utmost importance in relation to its correct **performance** and even, in some cases its very **survival**.

1707

INPUT BOUNDARY²⁾

"... the **set** of all **functions** which relate **environmental variables** to system **variables** in a unidirectional fashion" (W.T. POWERS et al., 1960, p.65).

These authors state that "... **environmental variables** affect, through some physical device, a system **variable**, but the device does not work backward" (ibid).

This concept is intriguing: since, while it characterizes a boundary as functional (as it really is indeed), it leaves open the question to find out where does really a boundary begins and ends. Is the stomach internal lining, for example, as a **part** of the digestive tract also a **part** of the boundary?

1708

INPUT PROCESSING^{1) - 2)}

"The **operations** that provide for (1) the **interaction** between the system and its **environment**, (2) the identification of systems-relevant input, and (3) the introduction of systems-relevant input into the system" (B. BANATHY, 1973, p.87).

Subsystems also have input processing devices. In this case, inputs generally come from other **subsystems** (**invironment**).

The following critical **subsystems** described by J. MILLER take part in input processing: **Boundary** (in general), **ingestor** (for **matter** and **energy**), **input transducer** (for information).

1709

INPUT TRANSDUCER²⁾

"The sensory **subsystem** which receives from **subsystems** or **components** within the system, **markers** bearing **information** about significant alterations in those **subsystems** or **components**, changing them to other **matter-energy forms** of a sort which can be transmitted within it" (J.G. MILLER, 1978, p.3).

This is one of the **20 critical subsystems** in MILLER's taxonomy of **living systems**.

1710

INPUT-OUTPUT ANALYSIS^{2) - 5)}

A technique for the study of **flows** in the economy in general or in an enterprise.

This technique can be used for **planning** or **forecasting**. It aims at the clear definition of the **interconnections** between some defined inputs and the corresponding outputs. This is generally done by using **input-output matrixes** (see hereafter). In this way, it becomes possible to establish the amount of output than can be obtained from a specified input, or conversely the amount of input needed to obtain a specified output, and eventually the **changes** that should be introduced in their reciprocal balance.

The technique can be applied in very numerous different cases relating inputs and outputs of materials, **energy**, **information**, labour, financial **resources**, or production of some item in relation to the market, etc...

There must be of course basic assumptions related to the constancy of **environmental conditions** and, for **planning** and **forecasting**, a **time** horizon of credibility about the **stability** of the same.

Input-output analysis can also be used in the study of **ecosystems**.

1711

INPUT-OUTPUT MATRIXES⁵⁾

The **representation** through a table with lines and columns of **flows** within a system.

This method has been introduced in economy by W. LEONTIEFF (1956).

The **flows** can be of **matter**, **energy** or **information** and take place between structural **elements** in the system. These matrixes are an alternative **representation** for **network diagrams**, totally or partly. As stated by H. ODUM: "Representing systems in this way is a first step in the use of techniques of matrix algebra by systems analysts". He adds, however: "A pertinent step after **description** as a matrix is to count the possible **relationships** that may have been overlooked" (1971, p.21).

This is indeed a many times forgotten necessity.

1712

INQUIRING SYSTEM (Design of the modern)¹⁾

Under this general title J.P.van GIGCH, J.L. SNELL and the Argentine authors E. HERRSCHER, P.E. PAVESI and P.F.J. PAVESI, published a series of papers in "Systems Research" (1988-1997). Their general aim has been to investigate the historical roots of the concept of inquiring system in the works of philosophers, scientists and even novelists of the past.

Among these appear Thales (600 B.C.), Lull (1232-1315), Descartes (1596-1650), Condillac (1715-1780), Kant (1724-1804), Destutt de Tracy (1754-1836), Cassirer (1874-1945), Hesse (1877-1972), Schrödinger (1887-1961), McCulloch (1898-1969), Feynman (1918-1988)

van GIGCH also considered the new approaches resulting from the introduction of the **computer** (1988). He may still conceivably return to this last subject since the accelerated evolution of the recent years.

1713

INQUIRING SYSTEMS (Hierarchy of)^{2) - 3)}

J.van GIGCH integrates inquiring systems into a more general **process** of **knowledge** formation: "The **hierarchy** of conceptual **levels** where higher **levels** of logic lend metarationality to lower **levels** can also be found in the **process** of **knowledge** formation... The **hierarchy** consists of four levels:

"**Level 1**: Or user's **level**, provides us with **facts** from **observations** of the real world. The problem of *universe of discourse* of **level 1** consists

of making **choices** among those **facts** to prepare a *descriptive model* of the universe of discourse.

"**Level 2: (the observer's level)**, the descriptive **model** is elaborated into an *explanatory model*. Here the problem consists of making **choices** among descriptive **models** to elaborate *hypotheses* and the most plausible *explanatory model* which accounts for the observed **facts**.

"**Level 3: (the designer's level)**, explanatory **models** become *prescriptive models*. The **designer's universe of discourse or problem** is to convert explanatory **models** into *prescriptive models or theories*. The role of an explanatory **model** is to merely account for a system's **behavior ex-post**, whereas the role of a prescriptive **model** is to anticipate its **behavior ex-ante**.

"**Level 4: (the epistemologist's level)**, choice among prescriptive **models** or theories leads to the elaboration of an *epistemological model, or paradigm*" (1986b, p.92-3).

This is the general recipe for inquirers and **designers** to avoid being naïve.

1714

INQUIRY (Cycle of)²⁾

P. LEDINGTON describes as follows the "five steps (that) provide an organized approach to inquiring about the **situation**":

"First, investigate the **situation** and gain an intuitive **understanding** of it;

"Second, grasp some basic names for ideas that are felt relevant to that **understanding**;

"Third, formalise the ideas into **models**, using some **rules** of formalisation;

"Fourth, compare the **models** with the features of the **situation** and assess the areas of match and mis-match;

"Fifth, evaluate attitudes towards the **situation** in terms of **problems** and courses of **action** based upon the revised **understanding** that has emerged from the formal **process** of inquiry" (1992, p.51).

As systems and **situations** have the bad habit of never stay put, S. BEER should surely add: and start it all over again, and again, as many times as needed.

1715

INQUIRY SYSTEM^{1) - 3)}

"A system of interrelated **components** for producing **knowledge** on a problem or **issue** of importance" (I.I. MITROFF and H. A. LINSTONE, 1993, p.29).

This definition is adapted from C. WEST CHURCHMAN (1971), who described the evolution of the concept of inquiry system from LEIBNIZ to SINGER and proposed his own synthesis, within the frame of a wide epistemological analysis.

CHURCHMAN's views have deeply influenced the following generation of systemists interested in inquiry and inquiring systems.

MITROFF and LINSTONE make the following points:

"First, every I.S. has or accepts, distinctive **inputs** from the "outside world"... The **inputs** that a particular I.S. recognizes as legitimate are not necessarily recognizable by other I.S.'s...

"Second, different I.S.'s employ different kind of **operators** (i.e.) the **mechanism** that operates or works on the basic **inputs** to transform them into the final **output** of the system, or **knowledge**...

"Third, the **output** of an I.S. is what the system regards as a valid **knowledge** for **action** on an **issue** of importance

"Fourth, the most critical **component** is known as the *guarantor*..., the **component** guaranteeing the **operation** of the entire I.S. itself" (p.30).

These statements imply that any I.S. is based on **criteria** defined by the inquirer or, in other words, is based on definitory subjective appreciations. This is unavoidable, but rarely perceived. Methods to clarify those **criteria** should always be used (See for example J.van GIGCH's **meta-levels**, J. WARFIELD's methodology to manage "**spreadthink**" (i.e. seek **consensus** when facing widely divergent opinions) and G.de ZEEUW's **invisibility**).

Note: Most authors do not seem to make a distinction between "inquiry" and "inquiring" systems. In some cases, "inquiring" systems could be compared with H.von FOERSTER "**observing**" systems.

1716

INSTABILITY^{1) - 2)}

Condition of a system or **process** led by a **fluctuation** of a critical **variable** out of its **homeostatic stability channel**.

Dynamic stability's main characteristic is that the system **oscillates** periodically within defined **limits** of **amplitude**, without ever leaving the established **fluctuations channel**, or **domain of attraction**.

Instability, on the contrary is a **runaway process** with a finite **time** course, through a succession of ever amplifying **oscillations** which lead the system closer and closer to the **limits** of its **stability channel** until a critical **threshold** is neared and the **process** undergoes a basic **change**. At that point the system reaches **metastability** and the slightest supplementary **disturbance** – even a small **random** "push" – turns it unstable, destroys it (the most common case for individual systems) or, rarely, shifts it toward a different form or **organization**.

Instability is closely related to **environmental** conditions, as stated by R. FIVAZ: "...instabilities have the property to bind conditionally the internal **structure** of the system to the value of an external **field**. This conditional bind is certainly a necessary ingredient to construct a **complex system modelization** inasmuch as such systems interact with the outside constantly, albeit selectively.

"In addition, real **situations** are characterized by unpredictable variations in the **environment** which submit systems to a succession of independent and **random fields**" (1991, p.22).

The most significant perturbing influence for a system is a high increase of the rate of **energy** intake, which is the factor that leads it to giant **fluctuations**. In **human systems**, such increase is induced by the system itself (technical advances in the captation and uses of **energy**).

More recently, the **boundaries** of **stability** and instability have become quite blurred, through our new **understanding** of **deterministic chaos**. It becomes rather difficult in the case of a **nonlinear system** to know if it is inherently stable, **metastable** or unstable, since it may fluctuate wildly and frequently bifurcate, with the possibility that it may cross an **instability threshold**.

In some cases, the concept of instability should however be relativized. According to C. HOLLING, many systems have alternative **dynamic stability** conditions, within more global conditions of **stability**, as they may leap from one **domain of attraction** into another under the impact of some very strong and unusual **perturbation**. HOLLING writes: "...many examples for the influence of **random events** upon natural systems... suggest that instability, in the sense of large **fluctuations**, may introduce a **resilience** and a capacity to persist. They point out the very different view of the world that can be obtained if we concentrate on the **boundaries** to the **domain of attraction** rather than on **equilibrium states**. Although the **equilibrium-centered** view is analytically more tractable, it does not always provide a realistic **understanding** of the system's **behavior**" (1976, p.81).

In such cases, we could possibly speak of an **endogenous ergodic** instability. While unstable, the system at least keeps its **identity**.

An interesting comment by Y. SINAI connects instability with **randomness**: "The more unstable the movement, the more **stable** become the manifestations of **randomness**. The instability of a non-aleatory **dynamics** leads to the rise of **randomness**" (1992, p.87).

1717

INSTABILITY (BÉNARD's)^{1) - 5)}

A **dissipative structuration phenomenon** that appears in a heated liquid.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

This **phenomenon** discovered in 1908 by the French physicist BÉNARD, has been the first observed **dissipative phenomenon**, ... in a jar of heating water. It implies the **transition** from a microscopic **level of action** to a macroscopic **level of organization**, which embraces a gigantic number of micro-**elements**.

R. LEFEVER and I. PRIGOGINE describe it as follows: "For a small difference of temperature, heat is conveyed by conduction, without any convection; but when the imposed temperature **gradient** reaches a **threshold value**, the **stationary state** (the fluid's **state** of "rest") becomes **unstable**: convection arises; it increases the **rate** of heat transfer and corresponds to the coherent motion of a huge number of molecules. In appropriate condition, the convection produces a complex **spatial organization** in the system" (1986).

Dissipative structuration transforms **chaos** into **order** (J. BRIGGS and F.D. PEAT, 1989, p.137).

Of course, this is not "a free lunch". As noted by PRIGOGINE: "The price is **entropy**! When we heat the system from below, most of the heat **flow** is lost, but some part of it is used to produce the **pattern**" (1989, p 7).

The resulting **organisation** takes the form of **hexagonal convection cells**. (See: "Hexagonal space filling").

1718

INSTITUTE FOR THE STUDY OF COMPLEX SYSTEMS (ISCS)¹⁾

This Institute is seated at 119, Bryant Street, Suite 212, in Palo Alto, California, CA 94301, USA.

Under the leadership of Peter CORNING, it focuses on "functional approaches to the **evolution** of **complex systems** as opposed to **autocatalytic**, **self-organizing** or law-governed approaches". Its "roots are in biology, not physics" (personal communication)

1719

INSTITUTIONALIZATION⁴⁾

"The translation of abstract cultural **elements** into action **norms**, **roles** and **groups** in order to instaure a more or less direct **control** upon social **interactions**" (After J.C. LUGAN, 1993, p.48).

This **process**, described by T. PARSONS, leads to the shaping of social **structures**, and tends to reduce **fluctuations** within the **social system**. It is a form of **regulation** and leads to social **homeostasis**.

It may however become a stumbling block if a **social system** faces a need for really crucial **changes**.

1720

INSTITUTO ANDINO DE SISTEMAS (I.A.S.)¹⁾

I.A.S. is the Peruvian Systemics Institute. It was founded in the 80's in Lima Peru by Eng. R. RODRIGUEZ ULLOA, who is still its President to date (2004). It has also a branch in the northern Peruvian city of Trujillo.

It publishes a series of pamphlets on "Systems Thinking and Total Quality" (in Spanish) as well as the six-monthly Journal "Sistémica", on "the inter- and **transdisciplinary management of complexity**". It also co-published Ch. FRANÇOIS's Spanish "Diccionario de Teoría General de Sistemas y Cibernética" (1992) and R. RODRIGUEZ DELGADO's "Teoría de Sistemas y Gestión de las Organizaciones" (1994).

I.A.S. organizes tutorials and seminars on a variety of subjects, mainly oriented towards the **management of complexity in organizations**. It also organizes "International Work Conferences". The 2nd one and most recent took place in Trujillo on "Sustainable **development** in societies and **organizations** with limited **resources** and opportunities" (December 1994), with the presence of Argentine, Chilean, Colombian and Mexican systemists.

Information on Congresses and Seminars of the IAS are at:
<http://www.iasvirtual.net>

1721

INSTRUCTION (Systemic)⁴⁾

A method aiming at a better **integration** of specialized **knowledge** with a global **understanding** of complex **situations** and systems.

Not only did instruction slowly pushed **education** (psychical and social) out of the classrooms and auditories. It has also gravely curtailed its own scope by encouraging more and more narrow specialization in evermore limited and isolated fields. This undoubtedly corresponds to the practical needs of our highly technified contemporary societies and seems thus unavoidable.

It however leads to a growing **segregation** between evermore numerous and particularized disciplines, and this destroys the capacity for synthesis, intercommunication and global approach to **complexity**.

Systemic instruction seeks to restore such a capacity for synthesis by creating a conceptual and methodological **language** usable to create bridges between specialists from different disciplines.

The acquisition of any specific **knowledge** seems to be a **process** of creation of **frames of reference**, i.e. the specific cerebral **organization** which reflects these frames and the capacity to modify them, or create new ones, when necessary.

This is probably closely related to the progressive **organization** by adequate training of neural **circuits** in the neocortex.

The systemic **language** contributes to this **process** by the use of fundamental and confirmed **analogies** and, still better when possible, **homomorphies** and **isomorphies** between structural and/or functional **models** elicited from various disciplines. It also establishes general concepts related to the global aspects of the **situations** and systems under **observation**.

This dictionary aims to make a critical census as complete as possible of these **analogies**, **homomorphies**, **isomorphies** and concepts as well as of the ways and means to use them.

1722

INSTRUMENT¹⁾

"An **object** that co-produce the outcome of an individual's or system's **action**" (R.L. ACKOFF & F.E. EMERY, 1972, p.31).

ACKOFF and EMERY write: "The co-production is itself produced by the individual or system. Thus an instrument is a device used by a functional individual or system in its functional **behavior**... The instrument employed by an individual or system operating at any functional **level** is always at a lower **level** than the **level** of the individual or system that uses it" (Ibid).

→ **Man-machine system**

1723

INTEGRABILITY²⁾

V. CROQUETTE states: "...all **linear** problems can be integrated". (1989, p.68).

Such problems correspond to the **behavior** of systems submitted to only one or two independent periodic **oscillations**.

CROQUETTE adds: "On the contrary, for **non-linear** systems, the determination of the characteristic **modes of behavior** is quite more difficult and, in most cases downright **impossible**. The notion of non-integrability is thus closely related to the **nonlinear** character of the system, even if there are some integrable **nonlinear** systems, as the pendulum, for example" (Ibid).

1724

INTEGRATE AND FIRE MECHANISM^{2/4)}

A natural mechanism that leads to the **synchronization of two oscillators**.

Ian STEWART writes: "... the **oscillations** are created by a **mechanism** known as integrate and fire. In such a setting some quantity builds up (that is, the **phase** increases) until it reaches a **threshold**. Crossing this value triggers a sudden action - fire (or in the case of fireflies, flash) - after which the quantity resets to zero and starts to accumulate again...

"Such **oscillators** are said to be "coupled", meaning that one affects the **state** of the others. The classic example is the **observation** made by the great Dutch physicist Christian

HUYGHENS (1629-1695) that pendulum clocks on the same shelf affect one another through the vibrations of the shelf" (I. STEWART, 1999, p.86).

As the **elements** in the **coupled oscillators** interact in an ordered and **cyclical** sequential way, this **phenomenon** is thus a very basic social one.

1725

INTEGRATING MECHANISMS^{1) - 4)}

Integrating mechanisms are a general feature of organized systems. They exist at every **level** of **complexity**, at least from the atomic one up to the social one. They are always relational mechanisms, based on some complementarity or some response to an external **constraint**.

An extraordinary biological example is the production of acrasin in the slime mold *Dicystostelium discoideum*, when starvation sets in within a **colony** of this **organism**, as a result of overpopulation within an **environment** limited in **resources**. (J.T. BONNER, 1988, p.231).

The search for the corresponding mechanisms in **sociosystems** is not yet systematic and no definitive conclusions exist until now. However, **norms**, beliefs, ideologies and scientific or philosophical **paradigms** are probably integrating mechanisms, resulting from the necessity to collectively face **environmental** pressures.

1726

INTEGRATION^{1) - 2)}

1) An **operation** intended "to make the **components** of a system increasingly fused and interactive" (B. BANATHY, 1973, p.87).

2) The state of a **whole** whose **components** are closely interactive.

W.C. ALLEE et al write: "Division of labor and integration are associated principles. Integration has no **function** unless there are differentiated **parts** that must act in relation to the **whole**. Specialization of **function** cannot occur unless the specialized **parts** are coordinated. Efficient **homeostasis** follows an increase in the special **functions** of the integrated **parts**. These principles apply to every **organismic level**, from the **cell** to the **ecosystem**, but are particularly well exhibited by the **population** of a **colony** of social insects" (Quoted by Ch.H. LAWSON, 1963, p.114).

R.N. ADAMS states: "...when a **level** is formed it not only receives **inputs** from its **components** but also involves **self-organization** at each **emergent** higher **level**" (1988, p.183).

Any progress towards integration supposes **constraints**: any integrative **operation** specifies well defined **interactions** among **parts**, generally by preventing other **interactions**. M.

DODDS and G JAROS write: "Integration... represents **pattern** and **order**, it tends toward simplicity and **cohesion (morphostatic)**" (1994, p.1417).

It also supposes the **emergence** of a higher **level communications network**, whose links precisely define the newly instated **constraints**.

Composite systems are less integrated than **complex systems**. **Complexity** is indeed closely related to integration since the better specified and more precise definitions of **interactions** tend to lead towards more **differentiation** of the various **parts** of the system, which thus becomes more **heterogeneous**.

Integration of very **complex systems** is more difficult and costly, as the number of **components** and **subsystems** increases, since more – and more complex – **regulators** are necessary to maintain **homeostasis**.

Integration is, in principle, an irreversible **process** or **state**. The break-up of the prescribed **interactions** – even when crossing quite narrow **limits** – leads to the systems **disintegration**.

The integration **process** is linked to the progressive emergence of **constraints** within the system: **rules** of **behavior** of the **elements**, **rules** for their **interactions**.

In ASHBY's terminology, an integrated system is more or less richly **joined**.

There is an optimum **level** of **integration** for any specific system, which is, unfortunately, very difficult to perceive and, still more so, to specify. Below this **level**, the system is not as efficient as it could be. Above it, it becomes clogged and slow to react to any inside or **environmental disturbance**.

In any case, the system retains its **adaptability** and **efficiency** only when it still counts with sufficient **redundancy**.

1727

INTEGRATION as a dynamic process^{1) - 2)}

As a process, integration is in J. KHAN's words: "The **coordination** of all **elements** in a shared and mutually beneficial **order**" (1992, p.991). Such a **process** is progressive, but may result, at a critical moment, in sudden clinching.

As observed by J.L. LEMOIGNE, integration is not a **state** of a system, but on the contrary an aspect of its **dynamics**.

The system's **activity** must be **permanently** coordinated, and not merely once under the guise of a stiff diagram.

LEMOIGNE writes: "The static diagram of a **net**, many times termed in theory of **organization** as a flow chart (note: in French: *organigramme*), only shows the prohibited (or *supposedly obligatory*) **interconnexions** and does not reveal by itself the potential properties that could result from (some other) possible **connexions**" (1977, p.194).

Any **description** of a system under the guise of an unique instantaneous and supposedly permanent **state** is an unwarranted reduction of the system's concept itself: any **structure** offers a double **synchronic** and **diachronic** character, which corresponds with the various aspects of a functional **process**.

1728

INTEGRATION (Levels of)^{1) - 2) - 4)}

The different **hierarchic levels** at which a system can be viewed.

Integration of **perception**, **understanding** or **organization** is, at its best when structured in **hierarchic levels** (without authoritarian connotations).

The perceiver or **decider** acting globally must disregard many details, as irrelevant for a comprehensive **synthesis**, in order to acquire a general **understanding** of the system and be able to manage it.

However **perception**, **understanding** or **management** must be translated into specific and practical **action** at different **levels**, from wide-reaching to minute and local **operation**.

At each **level**, there is a specific **mode** of **action** and, while the active **agent** must be specialized, she/he must also have sufficient notions about what is going on at the wider or narrower **level** and of his or her place in the global **set**.

1729

INTEGRATION (Social)^{1) - 4)}

According to G. SOMMERHOFF social integration results from the existence of **directive correlations** between individuals. He writes: "Complex **patterns** of **directive correlations** may exist not only between an **organism** and its **environment**, but also between members of an **aggregate** of individual **organisms**... they can impart a measure of organic integration and unity to such an **aggregate**" (1969, p.190).

If the existence of **directive correlations** is permanent and "... if one of the ultimate **goals** of these **directive correlation** systems is to preserve the continued existence of the social **aggregate** for its own sake, the **aggregate** itself may come to function as a biological unit in a way formally not unlike that of a single **organism**" (ibid).

SOMMERHOFF adds: "A social **aggregate** as a **colony** of insects is not a physical unit in the above sense (*i.e. in the sense of an organism*), but it can still be a biological unit in the same sense as above. Provided there is **communication** between its members, the physical prerequisites are satisfied that enable the **activities** of one member to become **functions** of the **activities** of the others" (ibid).

Translevel isomorphies described by J.G. MILLER from the **cell** to the social planetary **levels** finds here a very basic explanation. One

may also anticipate the possibility of a general theory of **associativity**, or **sociality**, whatever the nature of social **components** may be.

Another interesting connexion can be made with W.R. ASHBY's **Markovian matrixes** of statistical individual and collective **behaviors** of animal species.

Finally, the very recent **emergence** of collaborating **automata** seems to announce the possibility of future **automata** societies endowed with distributed abilities, able to organize themselves in a collective way by **directive correlations** in order to execute complex tasks in common.

1730

INTEGRATION (Vertical) ²⁾

The existence of various **hierarchic levels** of integration in a system.

As the system differentiates during its period of **growth**, it tends to need more and more varied **resources**, which must be extracted from its **environment**.

M. J. SIRGY and R. H. GILES Jr. state: "Large **organizations** usually strive to become vertically integrated (i.e. "intrabiotic") to insure **control** over **environmental resources**" (1986, p.239).

More varied **inputs** imply more diversified **subsystems** to transform and assimilate them and for elaboration of the resulting products.

More **diversity** means at the same time more **interactions** and more internal **conflicts**. Thus the need for **regulation** and **control** increases and, even, some meta-controls appear and with them a **hierarchy** of **structures** for **governance** of the system.

1731

INTEGRATION vs ISOLATION ¹⁾

More than contradictory or incompatible, integration and isolation seem somehow complementary forces.

J. T. BONNER writes: "It is an interesting paradox that at all **levels** of **complexity** there seem to be forces which bring **components** together, as in integration of **cells** into individual **organisms**, or gatherings of **organisms** into social **groups**; but at the same time there are other forces which work in the opposite direction and cause those individual **organisms** or those social **groups** to be isolated from one another. Curiously, the forces which seem to be working in opposite directions producing integration and isolation are the same; they are forces of natural **selection**" (1988, p.229).

In order to be able to establish *well defined interconnections*, based on reciprocal **constraints**, the **components** of any system must be separated from each others, but not to the point that **relationships** could never become

established. BONNER describes the different biological and ethological **mechanisms** which allow for these antithetic **processes**. For a good example, see "**Dictyostelium discoideum**".

1732

INTEGRATIVE TENDENCIES ¹⁾

"The characteristics related to the manner in which **holons** are **part** of larger **wholes**" (T.F.H ALLEN & T.B. STARR, 1982, p.270).

ALLEN and STARR comment: "These characteristics reflect the acceptance by the **holon** of the **constraints** placed upon it by more inclusive **holons**" (p.270).

1733

INTEGRITY (Systemic) ²⁾⁴⁾

"The degree of **congruence** between the stated (espoused) principles of **order** (e.g. **model** or *Weltanschauung*) and the principles of **order** by which the system actually operates" (Fuschl Conversation May 2000 on "Social awareness")

This notion is related to socio-cultural and political systems. When systemic integrity is low, the system is exposed to desintegration or at least deep and possibly traumatic **transformations**.

1734

INTELLIGENCE ^{1) - 3)}

"The apprehension of the relevant **structure** of the total **behavioral field**" (R.L. ACKOFF & F.E. EMERY, 1972, p.52).

ACKOFF and EMERY define "**relevance**" "...in terms of the immediate and presumptive future **purposes** of the actor" (Ibid).

This definition also fits, partly at least, **Artificial Intelligence**, as for example in chess **programs**.

According to W.R. ASHBY: "... the test of intelligence is the power of appropriate **selection**... As a result every intelligent system is subject to the following postulate: Any system that achieves appropriate **selection** (to a degree better than **chance**) does so as a consequence of **information** received" (1963, p.215).

However this does not seem to be enough.

The system must be able to **process** such obtained **information** in a satisfactory way. And if it does that, the problem of **understanding** how it acquired such capacity remains still open. ASHBY states that this results of some form of "preprogramming", which according to him, has been acquired by "five billion years of evolutionary molding all occurring in three-dimensional **space**" (p.216) and subsequent **learning**, within this pre-existing **frame**.

It is anyhow quite difficult to understand what intelligence really is without a deeper **understanding** of the devices that produce it: namely the **brain** and possibly the computer

(parallel or sequential? Hardware plus software, plus user ?). In ASHBY's words: "The living **brain** has had only one problem throughout **evolution**: how to get the necessary **information** in and how to **process** it with a reasonable **efficiency**" (p.217).

And now, we have the problem to explain how it did it. This is where the **connection machine** and other similar devices could possibly help us.

1735

INTELLIGENCE AMPLIFICATION ²⁾

"A **process** by which the power of appropriate **selection** is increased beyond the intelligence of the system which **controls** that **process**" (K. KRIPPENDORFF, 1986, p.40).

KRIPPENDORFF, taking as an example a computer programmed to play chess, writes: "... if that computer is programmed to compute more alternatives, recalls successes and failures with increasing perfection and makes better and faster **decisions** than its programmer could make, then it exceeds or will soon exceed that programmer's manifest ability to make informed **decisions**" (Ibid).

Thus, intelligence amplification is conditioned by **rules**, and meta-**rules**, which are used to understand **inputs**, select and perfect **responses**, and possibly invent some new ones.

1736

INTELLIGENCE (Distributed ARTIFICIAL) ⁵⁾

A technique leading to "...the construction of so-called multi-**agents** systems which permit modelization of the **behavior** of a **set** of more or less expert entities, more or less organized along kinds of social **laws**" (J. ERCEAU & J. FERBER, 1991, p.751).

ERCEAU and FERBER explain that "These entities or **agents** are endowed with a measure of **autonomy** and are immersed in an **environment** wherein and with which they interact. Accordingly, their **structure** is organized along three basic **functions**: to perceive, to decide and to act. They are physical entities (**sensors**, **processors**, vehicles...) or abstract ones (tasks to be executed, displacements,...), able to act upon their **environment** and upon themselves, i.e. to modify their own **behavior**. To do this they are endowed with a sketchy **representation** of that **environment**, and with perceptual and **communication** abilities" (Ibid).

The striking likeness of D.A.I.'s basic concepts with the basic working conditions of human societies may well be a harbinger of the shaping of societies of cooperative **automata**.

According to the authors the characteristics of these **automata** are of two different kinds. They should include:

- "eco-behavior" programs as for example satisfaction of needs, escape, aggression, return to satisfaction which would allow them to "... better their individual and community performance through learning-like mechanisms".
- specialized modules within the structure of every agent. We should thus have "communicating agents, rational ones, intentional ones and reactive ones" (Ibid).

1737

INTELLIGENCE (Distributed ARTIFICIAL)⁵⁾**Structure of the agents**

J. ERCEAU and J. FERBER distinguish and characterize in the following way the agents in D.A.I.:

Reactive agents: "They are of the lowest class. They only have at their disposal a reduced protocol and communication language and... their capabilities correspond merely to a stimulus-action law. The class of reactive agents include various levels, according to their capacity to gather and produce global behavior".

Communicating agents: "... which have at their disposal a complete communication protocol, but whose conversational and behavioral sections are mutually dependent ... The agents, at that level are unable to process such informations which are off the limits of their expertise domain" and thus "... the exchanges of informations are closely tied to the expertise existing within their domain".

Relational agents: "Each agent has at his disposal precise abilities, beliefs and a partial representation of its environment, including the other agents in the system. Task allocations mechanisms are incorporated for specific practical applications".

Intentional agents: They constitute the upper level: "Each of them is endowed with specific goals, partial plans allowing it to reach its goals, with intentions and beliefs, and the possibility to contract commitments which it must carry out, or contract other agents to perform some actions" (1991, p.757-8).

1738

INTELLIGENCE: Natural and Artificial^{1) - 3)}

To put this very general definition by ÖREN in perspective, let us quote R. FISCHER: "The most important is that the brain is self-determined, and cannot be programmed, without the consent of its Supervisor-Ego" (1992).

Leaving aside this last conceptual crutch, the self-determining brain can be understood as self-organizing, in terms of MATURANA, VARELA or VENDRYES' autonomy. Conversely, artificial intelligence in its classic sense, is not self-organizing. This could however not be any more true for future connection machines, constructed as parallel working networks.

ÖREN, having thus defined intelligence in very general terms, elaborates in the following way:

"... an advanced knowledge-processing ability implies the intelligence of an entity to be an ability:

- 1) for the representation of knowledge about itself and/or about some other entities;
- 2) for the generation, transformation, organization, location, selection, evaluation and analysis of different types of knowledge, as well as
- 3) for communication. The ability for communication requires the ability to answer and ask questions in a language (computer or natural language, including a spoken language) and includes abilities for perception, sensation, elicitation, acquisition, assimilation and dissemination of knowledge.

"Being an adaptive knowledge processing ability, implies that the intelligence of an entity is an ability for changing its environment or itself. The latter implies that intelligence is an ability:

- 1) for learning, which in turn implies abilities for generalization, abstraction and specialization of knowledge, and
- 2) for mutation, i.e. generation of self-modified versions of itself.

"Being a goal-directed knowledge-processing ability implies the intelligence to be an ability for:

- 1) goal setting
- 2) goal processing (including subgoal, goal modification, goal ranking, goal selection), and
- 3) goal-directed knowledge-processing (including goal-directed representation, generation, transformation, organization, location, selection, evaluation, and analysis of knowledge as well as communication and adaptation).

"A definition of artificial intelligence can then be: "The science and technology of knowledge processing using software that has goal-directed, adaptive, and other advanced knowledge-processing abilities. The aim of artificial intelligence can then be:

- 1) to find out about the nature of device-independent intelligence, and
- 2) to build intelligent machines (i.e. intelligent computers and intelligent computer-embedded machines) via advanced software" (p.5/6).

There remain, of course, lots of question-marks; for example:

- What is precisely knowledge, compared for example with stored data, information, or wisdom?
- How are goals formed? If a machine becomes able to form goals, what would be the interrelations between natural and artificial intelligent beings?

- To which extent is intelligence (natural or artificial) algorithmic after the necessary learning process?
- What does precisely self-modification mean?

1739

INTELLIGENCE (Swarm)

→ Swarm

1740

INTENTION³⁾

"The conscious will to reach a goal or to perform an action" (J. ERCEAU & J. FERBER, 1991, p.753).

ERCEAU and FERBER, who discuss this concept in relation to multi-agents robots systems, explain that reciprocal communication of intentions between participants of a network is an absolute necessity since: "Agents must be able to acquire informations about their environment and each other, either directly by their own perceptive devices, or by exchange of informations or, still, by learning" (p.754).

A theory of intentions has been derived by J.J. AUSTIN and R. SEARLE from their former theory of language acts established in the sixties.

1741

INTENTIONALITY¹⁾³⁾⁵⁾

"Goal-seeking directness toward the outer world" (C. EMMECHE, 1994, p.122)

This author comments: "This attention, a requirement for moving around in our living environment, can also be found among other organisms with well developed nervous systems" (Ibid).

The american neurologist W.J. FREEMAN has researched the neurodynamics of intentionality in animal brains, which he considers as the basis for intelligent behavior.

The first stage in the process is observation, whose cerebral effects can be seen through the use of electro-encephalograms. Even in the simple brains of salamanders, for instance, "the simplest actions, such as searching for food or evading predators, requires an animal to know where it is with respect to its world, where its prey or refuge is, and what its spatial and temporal progress is during sequences of attack or escape" (1998, p.4).

FREEMAN states that the limbic system (a relatively archaic part of the central nervous system) is the organ of intentional behavior: "... the necessary and sufficient part of the vertebrate brain to sustain animal intentional behavior is the ventral forebrain, including those components that comprise the external shell of the phylogenetically oldest part of the forebrain, the paleocortex, and the deeper lying nuclei with which the cortex is connected. These components suffice to support remarkably

adept **patterns** of intentional behavior in dogs, after the newer parts of the forebrain have been surgically removed... and in rats with neocortex chemically inactivated... "(Ibid).

A similar **concept** was developed earlier by the French philosopher M. MERLEAU PONTY, as "perceptive intentionality" (1945).

It has also taken a psychological meaning, whose multiple shades are not altogether very clear, as announced intentions do not always correspond to hidden ones, while the difference is difficult to fathom. Systemic psychology has still a long way to go!

It seems also to be somehow complementary to J.J. GIBSON's **affordance** (1986).

→ **Brain (Triune)**

1742

INTERACTION ¹⁾ - 2)

Any exchange between **elements**, **subsystems** or systems.

A. BAHM explains the concept of interaction within a system (an existing system in his terms, i.e. **concrete** or real, opposed to constructed systems, which are mental and cultural **models**):

"**Interaction**: The **whole** and **parts** of each existing system interact. That is, they act upon and influence each other (casually or conditionally) in ways that constitute it and maintain it:

"(1) Interaction involves **action** and **action** involves **change**. Each existing system changes. Existence itself involves existing or remaining through changing times, so every existing system involves **changes**, at least "changing times". A system may be involved in many kinds of **changes**, e.g. (a) **changes** within its **parts** (when a **part** changes internally it causes the **whole** to be a **whole** with a part changed internally); (b) **changes** between **parts** (becoming more like or unlike, more or less interactive); (c) loss of a **part** or **parts**, addition of a new **part** or **parts**, exchange of a **part** or **parts**; (d) **changes** in the **whole** (as more or less unitive, more or less strongly uniting its **parts**, or as a **whole** or more or fewer **parts**); and (e) **changes** in the **interrelations** of **whole** and **parts** (etc., more below).

"(2) Interaction involves permanence. Each existing system endures or remains the same from its beginning to its end. To be permanent is to remain through **change**. Interaction of **whole** and **parts** involves the **whole** remaining the same while it is acting on its **parts** (each **part** and all of its **parts**) and while it is acted upon by its **parts** (by each **part** and all of its **parts**). Interaction involves the **parts** remaining the same while acting on the **whole** and being acted upon by the **whole**. Interaction involves **interrelations** and **interdependence** of **whole** and **parts** remaining the same.

"(3) Interaction thus involves both **change** and permanence. Permanence and **change** involve each other because to be permanent is to endure or to remain through **change** and **change** can continue to be a **change** only by enduring or remaining a **change**. Both permanence and **change** may be variable, some systems existing for a shortest instant and some for a longest duration, and some characterized more by permanence and some more by **change**" (1986, p.178-9).

This kind of verbal fireworks, apparently somewhat paradoxical, becomes very meaningful when considered from the viewpoint of **autopoiesis** and **organizational closure**, which sustains that the **set** of internal interactions within the system is what defines which interactions it can operate with its **environment** and which not. These internal interactions lead to **cyclical** or **hypercyclical self-reproduction** of the system. Thus it maintains its permanence *thanks to change*.

On the other hand, interactions among individuals, i.e. elemental systems, as for example in ants **colonies**, are the driving force of communal **self-organization**, i.e. **sociality**. Interactions create at an **emergent level**, more complex units, endowed with new properties, simultaneously limiting and expanding the scope of individual activities.

The complete **set** of possible **interactions** within a system, when not too intricate, can generally be represented by a **Markovian matrix**. This idea has been adapted to sociology by W. BUCKLEY as the "interactions matrix" between individuals and small **groups**.

1743

INTERACTION DENSITY GRADIENT ²⁾

T.F.H. ALLEN and T.B. STARR explain: "At each point in **space** there is a certain **rate** of exchange of **information** or **matter** associated with a particular form of **signal**. At successive points in **space** there may be a **change** in the quantity of passing **signal**. Monotonic **change** in the amount of **signal** passing successive points constitutes an **interaction density gradient**. At surfaces, **interaction density gradients** are particularly steep" (1982, p.270).

1744

INTERACTIVE MANAGEMENT

→ **Management (Interactive)**

1745

INTERACTIVE PLANNING

→ **Planning (Interactive)**

1746

INTERCONNECTEDNESS ¹⁾

As the prefix "inter" implies **relationships** among **elements**, the term "interconnectedness" seems unnecessary **redundant**.

→ **Connection; Connectedness**

1747

INTERDEPENDENCE ¹⁾²⁾⁴⁾

1) The condition of **elements**, **subsystems** or systems which need of their **interactions** to maintain themselves.

A **whole** and its **parts** are also interdependent.

Considering that any **concrete system** depends on a specific **environment** and is related to other **concrete systems**, it can be seen that the notion of interdependence is fundamental in systems **hierarchies**, and as a base of the **concept** of **meta-** (or **supra-**) **system**.

2) A **situation** within such as a "**change** in one **component** brings about **changes** in others" (B. BANATHY, 1973, p.87).

Interdependence is instrumental for **autopoiesis**, a systemic **process** in which it is very strongly reciprocal and leads to a closed **cycle** of **reproduction** of the **components**, specific to the system.

3) **Relation** by which the existence of two or more **parts** is reciprocally conditioned by these **parts**.

J.C. LUGAN proposes a classification of different types of interdependences: "**linear**, **circular**, **dynamic**, **cybernetic**, **dialectic**, **contradictory**" (1993, p.117).

Interdependence is a characteristic of **complex systems** as opposed to **composite systems**, whose **elements** remain independent from each other (i.e. interdependent at most in a collective statistical way).

It increases in relation to the number and the types of **interrelations** between the **parts** and signals a growing **integration** and **heterogeneity** of the system.

Interdependence is also a basic relation *between* systems (and **groups** of systems) when significant **outputs** of the ones become **inputs** for the others, and reciprocally. Such a **situation** leads to reciprocal **regulation** and eventually to **integration** within a more global system. In such case, a new internal **organization** supersedes former intersystemic **relations** and we are back to **organizational closure** and **autopoiesis**.

Interdependence is a very basic feature in systems, starting with their very **emergence** from formerly unrelated **elements**.

Such a **relationship** implies **continuous** or **intermittent** functional **interactions** between the **elements**.

Reciprocity of the **interactions** tends to derive toward different possible **situations**:

- one **element** may manage the other or others in a simple hierarchical way, either through a natural **regulation** or by the use of a controlling **artefact**.
- one element may react to some **action** of the other through a **feedback**, that can be reiterative or merely occasional, and also be triggered only if some **critical value** is attained
- when the **interactions** become generalized and more or less permanent, the elements may tend to become **part** of a system of higher **level**
- different kinds of **associations** become possible, from still more or less loose intermittent connection to **commensalism**, **symbiosis** or **parasitism**.

Interdependence role is obvious at all **levels** of nature's **organization**, from subnuclear physics to the **man-planet system** presently in the making.

1748

INTERDEPENDENCE (Asymmetrical) ²⁾

The interdependence of upper and lower **strata** in a **hierarchized system**.

M. MESAROVIC et al state: "The requirements for proper functioning of a system on any **stratum** appear as conditions or **constraints** on the **operations** of the lower **strata**", and "... for a proper functioning of the system on a given **stratum**, all the lower **strata** have to function correctly" (1970, p.41).

1749

INTERDEPENDENCE (Declaration of) ^{1) - 4)}

Admitting reciprocal **dependence** in **organizations** and **social systems** is one basic condition to maintain their **coherence** and **efficiency**, as well as the individual physical and psychological well-being of their members and their good social **integration**.

A first "Declaration of interdependence" elaborated by the workers of the City of Portland Bureau of Maintenance is reproduced in G. and E. PINCHOT's work about the rise of the "intelligent **organization**" (1993, p.238).

The subject has been taken up by the **Fuschi Group** (1996) and will probably become a very important part of a systemic social science.

It is also related to the concept of **heterarchical organization**.

1750

INTERDISCIPLINARITY ^{1) - 3)}

An integrative **relationship** between two disciplines (Ch. FRANÇOIS, 1993, p.114)

Interdisciplinarity is less embracing than **multi-disciplinarity** and should not be confused with systemic **transdisciplinarity**.

According to Ch. FRANÇOIS: "Interdisciplinarity should be used only to describe a specific **interrelation** between two disciplines, as for example biochemistry, astrophysics or population genetics. This does not present many difficulties. It implies generally the bridging between two disciplines, since one needs of the other, or one brings new insights to the other. Any interdiscipline tends to become a discipline by its own right and supposes an excellent **knowledge** of both intervening **fields** and in many cases, of some mathematical **models** used as a lingua franca" (Ibid).

J.G. MILLER states: "The more general a scientific law is, the more powerful it can be because it applies to a larger class of **phenomena**. It is important, therefore, that there be more scientific effort devoted to testing a wide range of **cross-level hypotheses**. After all, the most recalcitrant problems now facing societies are not limited to single disciplines or single **levels**. Resolution of **environmental** problems, for example, often depends on **knowledge** derived from biology, the earth sciences, chemistry, biochemistry, engineering, economics, other social sciences, and the law. Increasingly, teams composed of experts in a number of **fields** work together.

"One difficulty that arises in so called interdisciplinary **cooperation** (in fact **multidisciplinary**) is the use of different terms, units, and dimensions, some of them applied only to a particular special **field**. The relationships among them are often unclear and it is difficult to translate them so that people who are not specialists in that **field** will understand them. One solution to this dilemma is to attempt to use the dimensions of the natural sciences as neutral reference points to which all other dimensions can be precisely related.

"It is helpful, also, to use neutral terms to recognize similarities that exist in systems of different types and **levels**. These should be as acceptable as possible when applied at all **levels** and to all types of **living systems**. For example, "sense organ" is one term for the **component** that brings **information** into a system at the **level** of the **organism**, but "input **transducer**" is also satisfactory, and it is a more acceptable term to engineers and at the society **level** (e.g. a diplomat or foreign correspondent). Such usage may irritate some specialists used to the traditional terminology of their **fields**. A **language** that intentionally uses words that are acceptable in other **fields** is, of necessity, not the jargon of the specialty. *Whoever uses it may be suspected of not being informed about the specialty*. The specialist **languages**, however, limit the horizons of thought to the borders of the disciplines. They mask important intertype and **interlevel** generalities" (1986, p.76).

Thus, for MILLER, even interdisciplinary cooperation needs a **meta-language**.

This does not however seems to be enough to save simple interdisciplinarity from its narrow limits. In D. McNEIL's words: "... we can be certain that our work will fail if it is not... centered around generality rather than "interdisciplinary" or any other arbitrary juxtaposition of particulars" (1993a).

Synthetically, a new **language** of general character, understandable by everybody, is urgently needed in order to put an end to disciplinary deafness, to "babelization" of the scientific community and to hermetic **compartmentation** between scientific and social actors.

This is particularly true in **management** sciences, as expressed by P. CHECKLAND: "What we need is not interdisciplinary teams but **transdisciplinary** concepts, concepts which serve to unify **knowledge** by being applicable in areas which cut across the trenches which mark traditional academic **boundaries**" (1976, p.127).

1751

INTERFACE ²⁾

A **region** of contact between the **boundaries** of two systems.

The concept is less rigid than the one of frontier or **boundary**, of more common use. The word evokes exchange, more than a more or less hermetic closeness.

J.L. TABARY, for example, bases his evaluation of interfaces on the study of biological **membranes**, which are "permeability barriers" in a selective way: **filters**, **osmose**.

This is indeed the case of any **boundary**.

Later on, TABARY developed as follows the **concept** of interface:

"...the interface **structure**, which concretely ensures the **subject/object** relation, is the stable and permanent **element** all along the **evolution** of the **subject** and the construction of a **phenomenal** reality. The constitutive properties of the interface overrule all the relations of the **subject** with its **environment**.

"There is a primeval **subject**, endowed with a minimum of **autonomy**, pre-existent to any encounter with the **environment**. However this **subject** does not practically know anything from itself and from its **environment** and must construct nearly from scratch its **knowledge** from itself and from reality.

"...

"An **autonomous system** cannot be **closed**, nor freely **open**: its relations with its **environment** require interfaces... It may not be freely open, otherwise it would be quickly destroyed.

"...The only solution is the controlled opening. There are of course permanent exchange **flows** between the inside of the system and its **environment**, but **autonomy** can be protected only if a strict **control** of these exchanges is maintained." (1991, p.171).

TABARY distinguishes two complementary types of interfaces:

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

"a) **the receptive interface** includes a **receptor** site at the external face of the **structure** which guarantees **closure** (cellular **membrane** for example) and an **effector** site on the internal face. The presence of a specific **agent** on the **receptor** site triggers a switch from a **state 0** to a **state 1**. This topple over is transmitted to the **effector** switch, which in turn switches and modifies some underlying **cyclical reaction**. Two essential features must be taken into account:

"The interface **response** is identical, whatever be the external stimulating **agent**. From the inside of the system no **input** can be qualified and only the monotonous switch of the **effector** site is known ("it is able to say how much, it cannot say "what" – von FOERSTER).

"The interface particularities remain absolutely stable during the whole life and the cognitive development" (TABARY, *ibid*).

The basic role of the receptive interface is thus to operate the **selection** and the **transduction** of the **inputs** for the use of the system. The role of the **effector** interface is opposite, as explained by J.C. TABARY:

"b) **The effector interface** includes a **receptor** site at the internal face of the **structure**, which guarantees **closure** and an **effector** site on the external face. The arrival of a specific **agent** (for example, a synaptic mediator) on the **receptor** site **triggers** a switch of the **receptor** site from a **state 0** to a **state 1**. This topple over is transmitted to the **effector** site, which in turn switches and this modifies the global **configuration** of the system, causing an **output** toward the **environment**" (p.173).

It should be interesting to try a generalization of these concepts in the cases of complex **social systems** (firms, **organizations**) and cultural ones.

1752

INTER-INFLUENCES ¹⁾⁽²⁾⁽⁴⁾

C. HARDY uses the concept of inter-influences between **elements** and **processes** as a general key to **self-organization** (1998)

Inter-influences do not only concern **interactions**, nor even recurrent **feedbacks** between elements.

In fact, inter-influences can never be perfectly described, and still less perfectly understood.

Multiples inter-influences are a basic characteristic of **networks** of all kinds. But they must be considered in relation to the **space** and **time** features of the network. Space is never really **isotropic** from the viewpoint of **propagation of effects**.

From the same viewpoint, no propagation is ever instantaneous and, moreover, the velocities are not **isochronous** and **time lags** fragment the general **determinism** of the network and may introduce a certain measure of **chaos**.

This partly explains the special type of **self-organization** known as **self-organized criticality**.

1753

INTERMITTENCE ¹⁾

The characteristic of a **phenomenon** or **process** which stops and starts by spurts at intervals.

The **behavior** of systems thus affected is dependent of the **recurrence** at **long time scale** of very important or massive **events** or **conjunction** of events. An example is the recurrence of glacial **periods** in Earth climate (see GOLDENFELD and KADANOFF, 1999, p. 87)

M. FARGE explains: "Spatio-temporal intermittence is linked to **distribution in space** of coherent **structures** and to **distribution in time** of the moments they connect and thus undergo strong **interactions**" (1992, p.240).

Other examples are volcanic eruptions, big earthquakes, crashes in stock markets, **epidemics in populations**, hurricanes in the Caribbean zone, typhoons and "El Niño" **events** in the Pacific Ocean. Intermittence generally implies sudden paroxystic **changes** or an epochal reversal in-between variable but long **relaxation periods**. It is related to **synergetic processes**, **power laws**, and **dissipative structuration**, all of these probably governed by great **fluctuations of energy inputs**, or their **cumulative long term effects** (*ibid*, p.87-89).

Intermittence is in some sense the manifestation of a kind of **memory** in a system that sometimes seems to behave randomly.

Intermittence is in many case a signature of **chaos**.

P. BERGE and M. DUBOIS state: "The characteristic **behavior** of intermittences is that of a **signal**, regular - **periodic** or **quasi-periodic** – during a certain **time span** and evolves to give during a brief instant a chaotic "puff": it then turns back to its regular **behavior** and the **process** starts again.

In this case the **chaotic behavior** is defined not only by the "puffs" but still more by the **random distribution** of the regular **period lengths**" (1992, p.150).

The **observation** of intermittences as tracers of probable **deterministic chaotic behavior** could possibly be useful for the study of many ecological, economic, historical and social **situations** and systems.

→ **Numbers (Prime); Periodicity; Term (short-, medium-, long-)**

1754

INTERNAL TRANSDUCER ^{1) - 2)}

"The sensory **subsystem** which receives, from **subsystems** or **components** within the system, **markers** bearing **information** about significant alterations in those **subsystems** or

components, changing them to other **matter-energy forms** of a sort which can be transmitted within it" (J.G. MILLER, 1978, p.3).

This is one of MILLER's **critical subsystems** in his **taxonomy of the 20 critical subsystems** in systems.

1755

INTERNALIZATION ^{3) - 4)}

"A **learning process** whereby the **components** or **subsystems** of a system acquire a **meta-system** that represents the requirements, **controls**, **goals**, **values** and **purposes** of that system and thereby relieves that system of some of its original **regulatory** and **control burdens**" (K. KRIPPENDORFF, 1986, p.41).

Internalization is of course a process proper to individuals in **human social systems**. It should be interesting to explore the possible existence of similar or equivalent **mechanisms** in animal societies and in biological systems.

1756

INTERNATIONAL ASSOCIATION for CYBERNETICS ¹⁾

This Association was founded in 1956 in Namur (Belgium) by a group of Cybernetists (J. DIEBOLD, N. WIENER, L. COUFFIGNAL, W. GREY WALTER, G. PASK, etc...). It received the sponsorship and material help from the Namur Province since its beginning. Its first President was a noted Belgian cybernetist, Prof. G. BOU-LANGER.

ST. BEER, H.von FOERSTER, W. ROSS ASHBY, H. FRANK and R. VALLÉE were also among the early members and collaborators of BOU-LANGER.

The Association organized a triennial Congress of Cybernetics in Namur since 1956. The 14th, and last to date, took place in 1995. The Association also published the quarterly journal "Cybernetica" since 1958, whose collection is one of the most valuable sources on cybernetics.

In the recent years, a stronger connection between cybernetics and systemics can be observed.

It should also be noted that, under the leadership of H. FRANK, the "Internacia Lingvo", better known as "Esperanto" was recognized as an official language in the Congresses, along with English and French.

Footnote: Unfortunately the I.A.C. has been dissolved in year 2000, due to the suppression of funding by the Belgian Province of Namur.

"Cybernetica", the 41 year old Journal of the Association, published its last issue (2/4, 1998) in 1999. Its suppression is a considerable loss for cybernetics

1757

INTERNATIONAL FEDERATION FOR SYSTEMS RESEARCH (IFSR)¹⁾

The Federation is the **organism** which coordinates the action of the international and national systems and cybernetic societies.

It was founded in 1976 by the following societies:

- The American "Society for General Systems Research" (Now "**International Society for Systems Science**").
- The "**Austrian Society for Cybernetics**" (Österreichische Studiengesellschaft für Kybernetik, Schottengasse 3, A 1010 Wien – Österreich)
- The "Dutch Systems Group" (**Systeem Groep Nederland** – University of Amsterdam – Groot Bickerstraat, Amsterdam – Nederland)

The Federation has presently nearly 30 member societies, African, Asian, European, North and South American.

Its seat is in Austria, thanks to the kind help of the Austrian Government. Its Secretariat is at Linz University, presently managed by Prof. Eng. G. CHROUST.

It publishes a quarterly Newsletter, featuring announcements of meetings and conferences, reports on the same, bibliographies, comments and general news.

Its official Journal is "Systems Research" (Ed. M. JACKSON).

It also sponsors the Fuschl meetings.

Its President and other authorities are elected for 3 -years terms.

For frequent updates and complementary information (in particular about member societies) please contact Prof. Gerhard Chroust: gc@sea.uni-linz.ac.at, or IFSR web site: <http://www.ifsr.org>

Prof. Yong Pil Rhee was the next President, succeeded in turn by Prof. Michael Jackson and Prof. Jifa GU.

1758

INTERNATIONAL INSTITUTE FOR APPLIED SYSTEMS ANALYSIS (IIASA)¹⁾

M.C. JACKSON describes IIASA as follows: "In 1972 the International Institute for Applied Systems Analysis (IIASA), a nongovernmental **interdisciplinary** research institution, was set up in Laxenburg (Austria), on the initiative of the academies of science (or equivalent institutions) of 12 nations. This Institute has been seeking to apply RAND-style **systems analysis** to major world **problems** related to, for example, **energy**, food supply and the **environment**... "According to the IIASA "handbooks", **Systems Analysis** aims to help public and private **decision makers** to resolve **problems** arising in **complex sociotechnical systems**.

"It brings to bear the tools of modern science and technology, searching for regularities in **system behavior** and to provide evidence about the **costs**, benefits, and other consequences of various possible **responses** to the **problem** at hand..."

"The **methodology of systems analysis** can be seen as consisting of seven major steps, as follows:

- Formulating the **problem**
- Identifying, designing and screening alternative **responses**
- Building and using **models** for predicting the consequences of adopting particular **responses**
- Comparing and ranking alternative **responses**
- Evaluating the analysis
- **Decision** and implementation
- Evaluating the outcome" (1992, p.76).

This **methodology** seems to have been oriented basically to technical systems **planning**, without participation of many **stakeholders** (notably people personally interested in the issues and politicians).

As a result, and very unfortunately, IIASA studies had scant impact on concrete complex **issues** from 1972 on.

1759

INTERNATIONAL SOCIETY FOR THE SYSTEMS SCIENCES¹⁾

Formerly: "Society for General Systems Research".

This was the original Society, created in 1956 in the U.S. by the founders: L.von BERTALANFFY, K. BOULDING, A. RAPOPORT and other scientists of various disciplines.

It has presently national divisions in Asia, Australia, Europe and North and South America, as well as a number of chapters in various states of the U.S., all represented in the ISSS Council. The Society has a number of Special Interest Groups (S.I.G.s) interested in specific uses of Systems concepts and **models**, as for example Law, Systems **Epistemology**, Climate change, Psychology, **Informatics**, etc... It publishes a quarterly "General Systems Bulletin" with announcements, comments, membership information, reviews and directories. It has also published annually for 28 years an important "General Systems Yearbook", with valuable collections of papers. (suspended since 1985).

It organizes a yearly meeting with numerous systemists who present and discuss their ideas.

The Society sponsors some of the main journals in the field:

- International Journal of General Systems (Ed. G. KLIR)
- Systems Research (Ed. M. JACKSON) fused 1997
- Behavioral Science (Ed. J.G. MILLER) fused 1997

1760

INTERNATIONAL SYSTEMS INSTITUTE¹⁾

This Institute was created in 1980 in San Francisco by B. BANATHY and other Californian systemists. Its seat is now in Carmel, CA. "It is organized as a **community** of scholars and practitioners and a **network** of institutions. It aims to apply systems and **design** thinking to:

1. create **models** and **methods** for the **design** of educational and other **human activity systems** and
2. to design and develop **resources** for systems and **design learning**" (as quoted from ISI folder).

ISI organizes international "conversations" that "provide opportunities for professional development in systems and **design** applications" (Ibid).

Its program "is carried out by Institute Fellows who pursue the work of ISI in their own **organizations** as well as in several ISI programs areas and research teams". (Ibid) ISI Fellows are from 20 different countries.

ISI has recently created a "Transnational Council" aiming at diminishing **transcultural** misunderstandings and **conflicts**. It is an active member of IFSR.

1761

INTERCEPTION²⁾

Self **perception** by a system of its own **involvement**.

In order to maintain itself a system must be able to maintain its **dynamic stability**, which is possible only if it has a sufficient **control** over its internal **state** and remains **autopoietic**. Well integrated systems possess a number of devices which allow them to exercise the needed **controls** or **regulations**, by some kinds of internal "**knowledge**".

In biological systems such a "**knowledge**" does not necessarily reaches the **level** of **consciousness**.

This seems to be also the case in **social systems**, at least in a collective sense, since in some cases, individuals duly perceive some abnormal internal **state** but are not able to awake the global attention of the **group**. This could be called the "Cassandra syndrome".

→ **Adaptability; General adaptation syndrome; Leveling mechanisms**

1762

INTERPENETRATION²⁾

Reciprocal influence between the internal characteristics proper to a given system and those resulting from its exchanges with other systems.

According to N. LUHMANN systems enhance their **complexity** by interpenetration without however merging. (see W. KARGL, 1991, p.582).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

1763

INTERPLAY→ **Interaction; Networking**

1764

INTERPOLATION²⁾

The determination of a **value** in a **function** intermediate between known **values**, using some procedure or **algorithm**.

The soundness of interpolations depend on the soundness of the procedure, because the regularity or **continuity** of the **function** may not be secure.

This in turn reflects the possibility that the modeled **process** may present unsuspected and irregular **variations** in the unexplored intervals.

Interpolations suppose a well established **determinism** of some kind and are thus very risky in **processes** that could be **chaotic** under a **deterministic** appearance.

1765

INTERPRETIVE STRUCTURAL MODELING^{2) - 4)}

A **methodology** that "provides the means to formulate a **pattern** or **structure** of **elements** associated with **issues** formulation" (J. WARFIELD, 1994b, p.219).

WARFIELD who introduced ISM, adds: "The **elements** may include **needs**, **constraints**, **objectives**, or options in a variety of fields such as **education**, public facility **planning**, city budget-cutting, or **system design**.

"This method is useful when a **complex issue** is under study, and there are **interactions** among the diverse **elements** of the **issue**. A focused **group** discussion on the **issue** is needed on the way to the development of one or more **relationships maps**.

"The **relationship** used in structuring must be transitive, and should be carefully chosen to arrive at the most useful outcome for purposes of interpretation. The **elements** that are structured as well as the **relationships** used to structure them are clarified by reasoning and discussion stimulated by the **process**. The quality of the results obtained depend upon skilled **process** leadership, which must be facilitative rather than **issue-involved**...

"The use of ISM produces one or more documented **models** of **elements interrelationships**. Part of the product will include a carefully refined **language** with which to describe or discuss an **issue** or system. There will be a significantly enhanced **understanding** of the **issue**, accompanied by modification and clarification of initially formulated **elements** and **relationships**" (Ibid).

WARFIELD provides a very extensive **description** of the **methodology**, that he also characterizes "...as a collection of **algorithms** designed to facilitate **group interaction**, **learning**, structuring, **representations** of **patterns**, amendments of **structures**, and interpretation of complex **issues**" (1995e).

ISM is an important tool at the beginning of any **process** of **problem** or **issue management**, or **systems design** and a basic feature of **Generic design**.

1766

INTERPRETIVE SYSTEMOLOGY¹⁾³⁾⁴⁾

A set of concepts introduced in Venezuela by H. LOPEZ GARAY and R. FUENMAYOR and applied and developed at the Universidad de los Andes (Mérida, Venezuela)

According to FUENMAYOR, Interpretive Systemology has its roots in the "**self-referential structure** of everyday living **situations**", which provides it with "a **phenomenological ontology**" (1991 a.)

The Mérida School uses Interpretive Systemology basically as a sociological **methodology** and as a tool for the study of typically Venezuelan situations, as seen from a **variety** of thematic interpretive **contexts**", i.e. different **frames** produce different **meanings**. Each of these represents a specific worldview. As an example, businessmen, priests, union leaders, politicians or bureaucrats have all different views about "Public Health Services".

Thus, debates between these various views are finally rooted in different interpretive modes of society, among them:

Social Darwinism: everyone vies for himself. The State has no role to play.

Radical Liberalism: the State must only insure fair competitiveness

Socialized Liberalism (i.e. Welfare state): the State must take care of those who were, or are unable to pay for their own welfare

Socialism: the State owns and manage everything and guarantees all social services to all citizens.

In synthesis Merida's Interpretive Sociology amounts to a systemically and **autopoietically** colored social theory according to which the ways a **social system** is considered is necessarily inscribed within one or another **interpretive model** (generally in a **recursive** style)

Of course all of the four **model's** types are ideological, i.e. biased in some way or another

While Interpretive Systemology takes its distance from all models (but possibly not the same distance from all), it still does not state why all these so varied theories of society need (or should need) an ideological fundamentation, blind of course in each case to itself in a selective way.

What would be needed is a good general theory of **ideologies**, as social and cultural self-generated organizers, including about the way they emerge in specific places and times. Such a theory should include for example the old Chinese mandarin state, or HAN FEI's legistic systems and the Hindu caste system, on the same footing than the North-american variety of capitalism, the Western concept of democracy or the Islamic sharia as basic law.

Of course, Interpretive Systemology could be a step toward this wider goal.

Note: FUENMAYOR's concepts are at least partly grounded in HABERMAS' critique of objectivism. He quotes HABERMAS' critique of HUSSERL: "...While criticizing the objectivist self-understanding of the sciences, HUSSERL succumbs to another objectivism, which was always attached to the traditional concepts of theory" (HABERMAS, 1972, p. 306)

FUENMAYOR also criticizes the "radical enlightenment" concept (whose aim was to escape the very strong rigidity of the traditional **values systems**). The Enlightenment, through MONTESQUIEU and ROUSSEAU, for example, pretended during the 18th C. to invent a constructed social way of being. However it is historically obvious that it is very difficult to fully disengage oneself, even from such a constructed cultural setting -obviously always based on an **ideology**. FUENMAYOR clearly believes that we should escape from even this form of subservience and become actors- or at least witnesses- in our own right. It seems to be quite a tall order. While absolute **objectivity** is a mirage, uncritical cultural relativism is a swamp because it is so difficult to take distance, from the deeply hidden prejudices one inherits from his/her own culture

In a critical comment of the Merida School work, J.C. MINGERS summarizes the proposed **methodology** as follows: " Briefly, this consist of:

- 1) developing a number of interpretations...of what the **phenomena** might be
- 2) comparing the phenomena with these different interpretations
- 3) conducting a debate between the various interpretations, given the results of the comparison

" This all leads, not to some particular result or agreement, but to a richer **understanding** and the possibility of further and deeper interpretations" (1992, p. 338)

M. JACKSON states, as a final **evaluation**: " Interpretive systemology is emancipatory... It demonstrate the oppressive role that **organizations** play in the power **structure** of the society" (2000, p. 299) As such, it is obviously a very useful tool. However "...using marxist ex-

planations allow the interpretive systemologists to assert their emancipatory credentials, but only at the expense of the **phenomenology** they claim to embrace" (Ibid)

Such a conceptual merry-go-round of **frames of references!**...And glints of GÖDEL's unavoidable **incompleteness** and the resulting **ontological skepticism**.

→ **Clanthink; Conversation; Design inquiry; Distinction; Frankfurt School; Metasystem transition theory; Observer; Weltanschauung**

1767

INTERRELATIONS ¹⁾

"The totality of **constraints** holding between the possible combinations of the **states** of two or more systems" (M. TODA & E.H. SHUFORD, 1965, p.26).

This subtle definition is also satisfactory if applied to **subsystems** within a system. In fact, what the authors thus define is the concept of "relation".

In some sense, it must be admitted that "inter-relations" is kind of a pleonasm, but it seems quite a useful one!

1768

INTERSUBJECTIVITY ^{1) - 4)}

The result of the **process** of mental and psychological **interaction** among individuals.

As **observers** gain **knowledge** of their **environment** only within the **limits** of their own internal perceptive and conceptual capacity (as a result of **organizational closure**), intersubjectivity, hopefully leading to **consensus**, becomes the unavoidable substitute for **objectivity**, which is merely an abstract and idealized **concept**. In K. KRIPPENDORFF's words: "Intersubjective verifiability is a weaker but more easily achievable form of **objectivity**" (1986, p.41). We would say, in this case, that the very **meaning** of "**objectivity**" must be deliberately adapted.

1769

INTRANSITIVITY ^{1) - 3)}

T.R. BURNS and L.D. MEEKER draw our attention on a very subtle **invisible** conceptual trap, which is the implicit belief in transitivity which pervades much of our thoughts:

"Intransitivities in Multi-Criteria Evaluation and Decision-Making

"A property of evaluation and **decision** orderings which has been of considerable importance in **decision-making** research and theory is that of **transitivity**: x preferred to y and y preferred to z and (thus) x preferred to z .

"Intransitivities, or **cycles**, e.g. x preferred to y , y preferred to z and z preferred to x , either have been ruled out, certainly in the case of "rational **decision-makers**", or have presented

a serious challenge to the classical **decision** and **games models** with their assumptions of uni-dimensionality (ordinal or cardinal utility scales) and **consistency**" (1976, p.115).

From their theoretical perspective, these authors consider that "... intransitivities are inherent in multi-**criteria** evaluation and **decision-making**. **Fluctuations** in the **criteria** used or in the relative importance of multiple **criteria** with respect to different **sub-sets** of items typically leads to violations of **transitivity**" (Ibid).

1770

INTUITION ³⁾

"A proposal solution to a problem without using a logical **process**" (St. KRIPPNER - pers. comm.).

According to H. POINCARÉ: "It is by logic that we prove, but by intuition that we discover" (1938)

Intuition is generally a "short cut", based on the formerly acquired mental **algorithms** - which may be mere beliefs - and produces a proposal by **analogy** often unconscious. Of course, the **validity** and usefulness of the proposal must be confirmed by making a critical appraisal preferably before and, in the last resort, after any practical experiment.

R. RODRIGUEZ DELGADO wrote: "Abstract intuition has not only perceptive aspects, but is also a qualitative synthesis of conceptual and affective experiences.

Space, time, duration, mobility, immobility, etc...can be experienced from within or can be formulated in definitions. In the first case, they are ineffable intuitions, in the second, communicable **concepts** "...and "Intuitions, as **perceptions**, are absolutely true as individual experiences, and cannot be rationally refuted, but they cannot pretend to be gnoseological **truths** or forms of the external **reality**. Reason can, of course, effect some comprehension of their mechanism and by this means intuition, perception and concept can be integrated, instead of remaining in frequent opposition" (1956)

→ **Autopoiesis; Cybernetics (2nd order); Observer; Ontological skepticism**

1771

INVARIANCE ^{1) - 2)}

A property not affected by some specified **transformation**.

The following classes of invariance can be distinguished:

- Shift invariance, by displacement of the item in conceptual **space**, as for example the group of permutations in arithmetics.
- **Scale** invariance, **similarity** at different **scales**, i.e. **homomorphisms; fractals**

- **Time** invariance, as for example regular **periodicities**.

- **Symmetry** invariance, through the rotation of some perfectly **symmetrical** figure as in geometry.

Conceptual invariance could be added, as for example **isomorphisms**.

B. WALLISER extends the concept to more global qualitative invariance, which maintains the basic characteristics of a system. He gives the genetic **code** in an individual as an example (1977, p.56).

An invariance can be external to the system: something which exists independently of it.

It can conversely exist or be constructed within the system.

This concept, translated into psychology, is a cornerstone of **constructivism**.

E.von GLASERSFELD writes: "A **rule**, no matter what it says or does, posits an actual or projecting regularity in our experience, something that is experienced more than once, something that is repeated and thus in some sense an invariance" (1976, p.115).

J. PIAGET showed how children progressively construct their **perception** of **permanent objects** (1970b) and later on, **permanent** concepts (1970a), i.e. how we acquire invariances, which become the basis of our mental and conceptual **organizational closure**.

In von GLASERSFELD words: "... it is the active **organism** that constructs an invariant item out of two or more experiences by holding on to certain parts of the experience and discarding others" (Ibid).

As explained by S. KATZ, the **constructivist** view is related to the **neural** computer **analogy**: "... (complex) invariances can be established in **neural** computers by means of weighted **summations** of **neural** currents arising from the **activities** of many endings. Hence, the invariances **emerge** as a result of **neural** computation and are not simply identical to, or **transformations** of, **structures** presented ready made to the nervous system. They are, in **Gestalt** terms, "**wholes**" that are more than the sum of their "**parts**", more than the innumerable local **effects** of sensory endings" (1976, p.44).

1772

INVARIANCE PRINCIPLE ³⁾

"We understand **change** only by observing what remains invariant and permanence only by what is transformed" (G. WEINBERG, 1975, p.155).

It is thus possible to perceive an invariant property only through **change** in some other one and reciprocally.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

1773

INVARIANCE (Summational)⁵⁾

The preservation of number in a **population**.

According to A.S. IBERALL, who introduces the notion, summational invariance marks a **trend** which can be verified not by dealing with individuals, but through generations.

IBERALL connects this idea with **thermodynamics**, which: "... is restricted to what it can describe in an ongoing **viable system**. It can only deal with **variables** which preserve fundamental properties upon **interaction**: so-called **cyclic variables**, or collisional invariants, or summational invariants" (1973, p.5).

The concept seems related to **critical thresholds** in **composite systems**.

1774

INVARIANCE (Systemic)²⁾

The degree of internal invariance of a system.

In E. LASZLO words: "Cohesiveness and **continuity** within the systems is higher, and rate of **change** lower, than in the **relations between** the systems" (1974, p.33).

Systemic invariance expresses the systems capacity for **self-reproduction**, **self-reference**, **autopoiesis** and **organizational closure**, as well **self-replication** by **hypercycles**. All these complementary properties gives them a considerable (if still limited) **autonomy** in their relations with their **environment**.

In fact, systemic invariance appears through global **transdisciplinary models** whose general characteristics apply to a significant number of systems of quite different kinds.

However, when modeled at a sufficient **level of abstraction**, the distinct models show common structural characteristics and functional **behavior**. As a result, the models are **isomorphic** (not so the systems or entities) and the general invariant properties of the systems become recognizable.

→ **Isomorphisms and Homomorphisms**

1775

INVARIANCE (Time)²⁾

The invariance of the **set** of **states** of a system that do not change in time.

What may change is the presence of the system in one or another **state**. Even so, this is a quite theoretical state of affairs, based mainly on the hypothesis that the different **states** do not influence each other.

According to H. MARGENAU (quoted by A.D. HALL & R.E. FAGEN) the absence of **time** in the equations describing a system is the very essence of **causality** (in its strictly deterministic sense). It is the case for "a system completely specified by n **variables** $x_1, x_2, \dots, x_n$. Then... the **state** of the system is uniquely describable by a **set** of n numbers. To borrow terminology from physics, the **set** of all points in n -dimensions is called **phase space**" (1956, p.25).

This type of **description** becomes thus an **algorithm** with a well characterized **content**, even if it may correspond to a **matrix** of probabilities. (See "**Markovian matrixes**").

However, "When the constants of the **set** become **functions** of **time**, as in progressive **segregation** or systemization, the definition is no longer satisfied" (Ibid).

1776

INVARIANT²⁾

A quantity, **relation**, **process**, **pattern**, **structure**, or generally property unaffected by any **transformation**.

Inasmuch as their basic conditions remain stable, invariants have a high predictive value.

1777

ENVIRONMENT^{1) - 4)}

The internal milieu of a system, separated from the **environment** by the **boundary**, or **interface**.

This is a neologism that this author considers useful and appropriate, because it reflects a well characterized and quite common **situation**.

The environment remains within precise **limits**, with the help of a **set** of coordinated **mechanisms** of **regulation**, which were described in **cybernetic** terms by P. VENDRYES in his noteworthy book "Vie et Probabilité" (1942).

In biology, it corresponds to the French physiologist Cl. BERNARD "milieu intérieur". In BERNARD's words: "In all living beings, the internal medium, which is a product of the **organism**, maintains the needed exchange **relations** with the external medium; but as the **organism** becomes more perfect, the organic medium specifies and isolates itself more and more of the external medium" (1864, reed. 1952).

W. CANNON's **homeostasis** is **dynamic stability** within the environment.

Human systems, such as industrial or business firms, **organizations** of any kind, nations, etc..., possess an environment which appears in the guise of recognized and generally codified values, **norms**, obliged or more or less tolerated of prohibited **behaviors**, **symbolic representations** like **languages**, specific **knowledge**, currencies, emblems etc., and a proper **space** of restricted access to those who are not **part** of the system.

Environment should not however be considered static. W. BUCKLEY observes that the internal **organization** of an **adaptive system** allows it to discern **changes** in its **environment** and discover adequate new **responses** to these. When these **responses** modify the general **behavior** and **processes** in the system, it may be said that its environment has adapted. (1967).

Globally however, the system's environment must remain **autopoietic** and cannot adapt too far away from its basic nature.

1778

INVISIBILITY³⁾

The non **perception** of some **objects**, features or **situations** due to the insufficiencies of our **observational competence**.

The concept, developed by G.de ZEEUW (1992, p.1071-1078), is related to H.von FOERSTER's **cognitive blindspots**: "We do not see what we do not see. **Objectivity** is a **subjects** delusion that observing can be done without him" (Declaration of the American Society for Cybernetics).

According to de ZEEUW the progress toward visibility is a result of the use of more embracing **observational languages**. However, and paradoxically, as observed by Th. SANDOZ: "**Knowledge** and ignorance are directly correlated... (they) grow together and mutually reinforce" (1993, p.1544).

Humanity passed from the magical and mythical **languages** to the rational one, which allowed for the understanding of **phenomena** governed by **linear causality** and **determinism** in its strong (Laplacian) sense.

While obtaining great successes, especially with all kinds of **mechanisms**, the classical logical-rational **paradigm** left misunderstood or downright concealed **nonlinear** relations and is not conducive to a clear **understanding** of complex entities.

According to de ZEEUW: "Nowadays, its (i.e. the classical rational observational **language**) use begins to create excesses itself, however, especially in the case of increasing **competence** for complex **activities** (activities depending on the continued interacting of many actors). It can be argued that the **observational language** limits itself in this way by imposing **models** on the actors in an **interaction**, that is imposes **criteria** for access to **interaction**. Breaking this limit requires new **languages**" (Ibid., p.1077).

A quite closely related concept is "implicitness", which in J. WARFIELD's terms, works "against **referential transparency**". He enumerates the resulting difficulties as follows:

- What constitutes a science is implicit
- Division of many component **concepts** are implicit
- The **Universal Priors** of Science may be treated as implicit, in the presentation of the science.
- **Definition** of concepts by **relationships** may be implicit in the science.
- The underlying basis of arguments in the Theory of **sets** may be implicit
- The underlying basis of arguments in the Theory of **Relations** may be implicit
- The foundations of science are implicit.

- In some instances, especially in newer areas of strategic behavior in response technology, even the theory is implicit" (1988, p.340). In short, we do not know *that* we do not know (and *what* we do not know).

The quick expansion of many conceptual tools addressed to **complexity** seems however to announce the **emergence** of a new and wider **language**, including for example Prigoginian **thermodynamics**, **fuzzy sets**, **catastrophes**, **fractals**, **connectionism**, **percolation** in **composite systems** and **chaos models**.

Such an expanded **language** could reduce invisibility.

In any case, in D. MEADOWS et al. words: "One can never be fully aware of all one's biases. But one can be aware that one is unaware and deliberately expose oneself to **situations** in which biases can be discovered (the best way is to 'hang out' with whomever one regards as the enemy)" (1982, p.278).

1779

INVISIBLE HAND: a systemic reappraisal ³⁾ - 5)

Adam SMITH's invisible hand was a dubious - if not gross - presystemic simplification.

In words of P.M. ALLEN: "Because of the fallacious **analogy** with the approach to **equilibrium** of an **isolated physical system**, in some way, there was an "invisible hand" guiding the **evolution** towards *the equilibrium state*, and hence in some sense that "governments" or "planners" had only to alleviate marginal areas of socially unacceptable inequality or hardship while **events** moved inevitably towards the *best solution*... Our new (i.e. **irreversible thermodynamics**) perspective tells us that this is not the case, that a **choice** of futures may indeed exist, and that these possible futures are of different "**optimalities**", some being more "efficient" for certain points of view than others" (1980, p.279).

This, of course, complicates enormously the **governance** of economic, social and political systems, as it introduces subjective - that is controllable and frequently contradictory - **evaluations** (which of course, were always present, if not acknowledged).

The "invisible hand" in fact, proposed a **homeostatic model** of economy and society, ignoring **instabilities**, **threshold crossings**, **emergence** and **chaos**. Such a concept is still implicit even in Keynesian economics and, of course in many technical tools used by economists.

1780

INVOLUTION ¹⁾ - 5)

"Natural shrinkage or decline of an **organ**" (H. SELYE, 1975, p.468)

A near synonym for "atrophy".

It seems that this **phenomenon** is proper to *any ageing system or subsystem* which is not anymore able to obtain the sufficient **inputs** of **resources** needed for its proper **maintenance**.

1781

IRREDUCIBILITY ¹⁾ - 3)

The impossibility to understand the global character of a system by merely studying its **parts**.

This is E. LASZLO's formulation of the non-**reductionist** stand of systemics (1974, p.212).

Systems are not merely **summative**, they are **integrative**, implying thus the existence of **communication networks**, **interactions** through many different **feedbacks**, selective **constraints**, and the consequent impossibility to understand fully the **parts** as working **elements** in the system, when their reciprocal horizontal and vertical **links** are severed, or simply not taken in account.

1782

IRREVERSIBILITY ¹⁾ - 3)

The **transition** by which **time symmetry** is broken.

The basic idea of irreversibility was developed in a rational way by the French philosopher E. QUINET (1870) and stated precisely by DOLLO (1893).

In 1924, A. LOTKA observed that absolute **reversibility** should be possible only if frictional resistances were totally absent, a completely illusory assumption in "real **processes**" which "are always irreversible" (1956, p.25-26).

A satisfactory theoretical basement for the concept of irreversibility has been finally established by I. PRIGOGINE and his Brussels school.

PRIGOGINE writes: "Rational mechanics knows only reversible **time**, whereas the direction of **time** plays a fundamental role in the biological and human sciences. It is true that in the Nineteenth Century the problem of the direction of **time** was incorporated in physics through the **second law of thermodynamics**. Still the contrast between the idea of **evolution** in physics and that in biology or sociology is striking. In physics, the increase of **entropy** expressed by the **second law of thermodynamics** shows a tendency toward a progressive "disorganization" of the system. On the other hand, biological or social **evolution** is accompanied by progressive **structuration**..." (1976, p.94). And: "Life corresponds... to an inscription of irreversibility into **matter**" (1985, p.9).

To explain irreversibility PRIGOGINE and his collaborators created the new **thermodynamics of systems far away from equilibrium**, which does not contradicts classical **thermodynamics** (quite the contrary), but generalizes it through new concepts related to **complexity**, such as **giant fluctuations**, **stability thresholds** and **dissipative structures**.

As a consequence of this work, the subjectivist interpretation of irreversibility (in physics and mechanics) as attributed to the **observer** incapacity to perceive the conditions of **reversibility** and to produce it, as could be done by **MAXWELL's demon**, is now abandoned, as well as CHANDRASEKHAR's argument, quoted by PRIGOGINE, that "a **process** appears irreversible (or reversible) according as whether the initial **state** is characterized by a long (short) average **time** of **recurrence** compared to the **time** during which the system is under **observation**". PRIGOGINE writes: "According to this point of view, irreversibility would appear as an artefact due to the **time scale** of **observation**!" (1989, p.77).

Sensibility to initial conditions, as a basic characteristic of **deterministic chaos**, results in a new understanding of the meaning of **irreversibility**.

1783

IRRITABILITY ¹⁾

Reaction of a system to reversible **disturbances**" (L.von BERTALANFFY, 1969, p.80).

According to BERTALANFFY, such **disturbances** are "smaller **waves** of **processes** surimposed on the continuous **flux** of the system... after which the system comes back to its **steady state**, and **autonomous** activities in **periodic fluctuations**" (ibid).

V. TURCHIN sees irritability as conducive to a **constraint** (F. HEYLIGHEN, pers.com.).

→ "**Resilience**"

1784

"IS" and "OUGHT" MODES in SYSTEMS HEURISTICS ³⁾

W. ULRICH, as quoted by R.L. FLOOD and M.C. JACKSON, proposed a "Critical Systems **Heuristics**", based on two types of questions.

The first type, the "What is" or "Who is" type of questions, aims at discovering the factual aspects of the considered **situation**. Examples are:

- Who is actually the **decision** taker?
- What is the actual **purpose** of the systems **design**?

The second type of questions is designed to explore unclear aspects of the considered **issue**, as for example:

- Who ought to be the client (beneficiary) of the system to be designed or improved?
- What ought to be the **purpose** of the system?

ULRICH offers in both cases a table of 12 critical questions (FLOOD and JACKSON, 1991, p.206-7).

1785

ISLAND EFFECT ¹⁾²⁾⁴⁾

The appearance and eventual multiplication of original types in secluded **environments**.

Such types can be vegetal or animal species, or specific and original cultural traits in isolated **human groups**.

Isolation favors **differentiation** of any original stock through to "creative" innovation in some specific **niche** in a **biotope**, or more generally, **environment**.

It may also lead to **co-evolution**, when unfettered or suppressed by alien **competition**, for instance by introduced species or characters. End of **isolation** usually leads to the quick alteration or even **destruction** of biological or cultural **diversity**. (Mac Donald may kill regional recipes and the Uros of Lake Titicaca are now adept to Salsa music)

1786

ISLAND SYNDROME ¹⁾²⁾⁴⁾

The diminished resistance to environmental **disturbances** in small systems.

Small systems offer very limited **variety**, because specific traits (genetic, or cultural, for instance) appear in very few individuals, thus becoming easily lost.

This can be observed for example in animal and vegetal **populations** in islands or in natural reserves or parks of reduced extension. A small **population**, with limited genetic **variety**, can easily be wiped out by, for instance, a newly introduced predator or pathogen.

Such an event may well trigger a more extended **instability** in the **ecosystem** and lead to crashes in other species (D. Quammen, 1997).

A similar effect has been observed in small aboriginal populations confronted with invaders. In Southern Argentina and Chile such populations were decimated by infectious diseases against which they had no immunity. Most of them finally became extinct and their cultural traits, as for example **language**, have been totally lost.

Cultural traits may also be lost when small populations accept new **beliefs** and ways of life introduced by colonizers.

1787

ISOCHRONIC (or isochronal, or isochronous) ²⁾

Character of the **propagation** of **effects** of some **event** which progresses permanently at the same velocity in all directions.

This condition is in practice very exceptional.

In fact, the very different **environmental** conditions may easily slow down or accelerate **propagation** in some directions and during some time.

This anisochronic **propagation** produces **time-lags effects** and limits the internal **coherence** of any system, as well as its **synchronization** with environmental conditions.

→ **Networks as imperfectly connected systems; Small world**

1788

ISOCHRONY ¹⁾²⁾

The character of **time**, whose **flow** is regular and uniform.

This definition presents some difficulties. In the first place, the **perception** of the flow of time is subjective. Moreover, if meted through its **effects** in biology, or mechanics, or whatever, different **rythms**, and **periodicities** appear, which can be compared only by clock-works, in itself a human construction (A. MIS-SENARD, 1940)

P.R. MASANI writes that time is "isotropic" - which means in his words that "the past-future distinction is objective" (1998, p. 71). Truly, "**isotropy**" is a property of **space** whose extension to time is debatable.

However iso- or anisotropic effects in the **propagation** of some **events** (for example a new technique) can be meted in terms of time.

1789

ISOLATE ¹⁾⁴⁾

A group of **elements** sharing some peculiar characteristics and, or **relationships** within some secluded **environment**.

This general **model** applies to some archaic human **populations** (for ex. some former Amerindian groups) or animal or vegetal relics.

Isolates are always in a dangerous position, being very vulnerable to any environmental **change**, as for ex. the introduction of some new species.

There are also cultural isolates, i.e. very small collectivities that maintain the last vestiges of a **culture**, or **religion** (for ex. the Parsis in India), or a **language** (for ex. the Guanches in the Canaries Islands before their overwhelming by Spanish colonists).

In most cases, the members of the isolate are well adapted to their existing surroundings, but at the price of losing their **adaptability**. This generally leads them to their doom.

1790

ISOLATION ^{1) - 3)}

A hypothetical **situation** of an entity, or system completely devoid of any **interrelation** with an **environment**.

This a pure **abstraction**, related to the theoretical **thermodynamical model** of the "**isolated**" system submitted to absolute entropical **decay**.

In practical **situations**, isolation should always be qualified, as relative, partial and/or selective in **space** and **time**.

1791

ISOLATION and REPRODUCIBILITY ¹⁾

According to N. PEGUIRON: "The isolation (of **processes** in order to study them) is used to show the specificity of the **effects** resulting from a **cause**: it is thus the basic instrument for seeking reproducibility. This act, when performed, implies the supposition that the essence of the **phenomenon** which is studied is retained; it thus restricts the field of investigation to the **isolated systems**: the properties of a (**connected**) system, basically resulting of its **interactions** with its **environment** totally escape from it" (1989, p.10).

Accordingly, the well known "...et ceteris **paribus**" principle, generally *implicit*, is usable only in order to obtain **abstractions** that can be applied to monocausal and repetitive **situations**.

PEGUIRON adds: "But there is something worse: If pushed to its extreme limit, the isolation **process** is an **abstraction** which is not only completely impossible to perform practically, but, should it be, would not let anyone to account for the **phenomena**, as we observe them" (Ibid).

It must be however recognized that, without the isolation (and basically **reductionist**) **method**, it would not have been possible to start the upbuilding of modern science and, 350 years later, finally tackle **complexity**.

1792

ISOLATION (Functional) ²⁾

"Separation of an entity from its **environment** by virtue of its relatively more rapid intrinsic **reaction rates**" (T.F.H ALLEN & T.B. STARR, 1982, p.268).

ALLEN and STARR state: "Entities may be functionally isolated while being spatially interdigitated with that which comprises their **environment**" (Ibid.).

This seems to correspond to St. KAUFFMAN's **frozen cores**.

1793

ISOLATION MECHANISM ¹⁾

The division of a **population** in two or more separate **populations** by severance of their **communication links**.

This concept applies to "**populations**" in a very generalized sense. It can be observed in animal and vegetal species (see J.T. BONNER, 1988, p.236), but also, for example in linguistics, where the phonemes and words, being carried by numerous individuals, are assimilable to **populations**.

It generally results in a progressive **drift** and growing differences between the **groups** that have been cut off from each other. This **mechanism** is specially effective when the condi-

tions in the respective **environments** become sufficiently differentiated to **filter** in different ways the **random** individual mutations or variations that occur.

1794

ISOMORPHISM ¹⁾ - 2) - 3)

"A **mapping** which not only involves a one-one correspondence of **elements**, but which also preserves operational characteristics" (1968, p.108).

As St. BEER explains, this means that the results of an **operation** on **elements** of one **set** correspond to the results of the analogue **operation** on their homologues in the other **set**. Thus, there are also relational isomorphisms, which are much more interesting than structural ones.

While an isomorphism may be considered as the perfect **analogy**, no **model** is ever totally isomorphic to the modelled **object** or system. The really significant use of isomorphism is to allow for the creation of *classes of models* characterized by the same properties. This enables us, up to a point, to compare **structures** or **functions** of different **concrete systems** and operate meaningful generalizations. This in turn permits us a certain degree of **algorithmization** of the **knowledge** of numerous complex **entities** or **situations**, which may be more or less similar. (thus leading to **algorithmic compressibility**).

L. TRONCALE uses the term "isomorphies" apparently as a synonym of "isomorphisms" and defines it as follows: "A formula, **pattern**, **structure**, **process** or **interaction** demonstrated to be precisely the same, but in general terms, across many disciplines, and many **scales of magnitude** of real systems despite the obvious difference of the **parts** of the diverse systems" (1985, p.47).

He comments: "Isomorphies are completely **context-independent** and **content-rich** (have **meaning** in themselves and alone). They are manifest only in **context**, and observable only by comparison of many **contexts**".

He goes still farther, adopting a quasi-platonic stand: "The existence of the same **interaction** across many separate **levels** implies that the isomorphy is actually as fundamental and real, perhaps more fundamental and real than the **parts** at different **scales of magnitude** that exhibit the **relationship**. In this formulation the abstract isomorphy-across-systems and the physical manifestations-of-systems are equally "real" (Ibid).

In a quite different perspective, and according to J.van GIGCH the search for isomorphisms could be computerized through some adequate software, as for instance APPLE's HYPERTEXT and HYPERCARD. (1988, p.269). Quoting J. SCULLEY, he writes: "... the computer will con-

fer the (power and) perspective to compare and contrast (read: 'find isomorphisms') and so free ourselves from the limits imposed by specialization" (Ibid.).

1795

ISOMORPHISMS and HOMOMORPHISMS ¹⁾ - 2) - 3)

Isomorphisms should be carefully distinguished from homomorphisms.

According to R. VALLÉE, the **pluridisciplinary**, (or better, **transdisciplinary**) character of **systems theory** "... is a result of one of its fundamental **goals**, i.e. to show, in the best case, structural isomorphisms between systems pertaining to different disciplines (or between **representations** of these systems). Such isomorphisms, which most generally, if not always, are merely homomorphisms, were already heralded by **cybernetics**, as in the title of WIE-NER's work...

"This search for isomorphisms, or more modestly, homomorphisms, leads to the concept of **model**, which allows for the **representation** of a **category** of systems. The ideal of an isomorphic **representation** is however misleading. As KORZYBSKI reminded us, "the **map** is not the territory" (1990, p.56).

St. BEER enounces a similar opinion: "Having refined the conceptual **models**, the contents of mind, ... the scientist produces two deeper-level homomorphic **models** - and these may well be isomorphic with each other" (1968, p.113).

1796

ISOPLETH ²⁾⁵⁾

A line of equal value in a graphical **representation** (M. CHISHOLM, 1975, p.62).

Isopleth can be used for example to represent contour lines, rainfall, temperatures, atmospheric pressures, etc. It allows for a meaningful **connection** among many scattered **observations** through the grouping of numerous statistical ones. Two successive isopleths define an area wherein approximatively similar conditions do exist.

Their use is by no means limited to geography or meteorology.

→ **Choropleth**

1797

ISOPRAXIC BEHAVIOR ²⁾⁴⁾

A behavior "in which two or more members of a **group** communicate by doing the same thing". (P.D. Mac LEAN, 1978, as quoted by R. Numella Caine and M. CAINE, 1994, p.61).

A good example is wearing a badge of some **organization**.

"The constitutional part of us that reinforces **routine** has a powerful means of making it known when there has been a break in **rou-**

tine... In like vein, anything that reinforces **rou-tines** may have a reassuring, calming effect" (P. D. Mac Lean, Ibid)

Such behavior reinforces in a ritualistic way the **coherence** of the **organization**. It seems to be a more elaborate human form of some animal reciprocal signaling in **herds**, fish **shoals**, bird flights, etc...

1798

ISOTROPY ²⁾

The character of a **space** or **environment** presenting the same properties in all its extension.

Isotropy is quite an abstract concept, of mathematical origin. It is however useful to help the **understanding** of any **concrete environment**, which is merely *more or less* isotropic, respective to some property.

→ "**Anisotropy**".

1799

ISSUE ¹⁾

A **situation** generating a wide public concern.

This term is used by J. WARFIELD in his methodology of **Generic design** and "Interactive Management". See "**Management (Interactive)**".

1800

ITALIAN ASSOCIATION FOR RESEARCH ON SYSTEMS ¹⁾

The "Associazione Italiana per la Ricerca sui Sistemi" has been founded in Milano and Brescia by G. MINATI and a group of Italian systemists. It is sustained by the "Fundazione Barberini e Centoni per la Correlazione".

It organizes tutorials and international meetings.

A Computerized Enquiry System, or Semantic Information Retriever has been created by MINATI, who also published an "Introduzione alla Sistemica" (1996).

The Association is specially interested in didactics and education and closely collaborates with the OPPI, "Organizzazione per la Preparazione Professionale degli Insegnanti" (Milano) which has adopted systemic **methods**.

1801

ITERATION ¹⁾ - 2)

The **cyclic** repetition of some **process** or **routine**.

Iteration is much used in computation, to approach some desired result by progressive **convergence**.

Iteration is also the base for **recursivity** in **autopoietic** and **hypercyclic processes**.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

On the other hand, J. BRIGGS and F.D. PEAT state that, in **chaotic processes**: "It is the iterating nature of the **nonlinear** equations (that represent the interconnected nature of **dynamical systems**) which makes impossible the improvement of **predictions**" (1989, p.69).

J

1802

JAMMING TRANSITION²⁾

The blockage of a **flow** through overstuffing of flowing **elements** in a **channel**.

M. BUCHANAN gives the following example: "Put just a few beans or grains of coffee through a chute and they will flow quite easily. Try to send too many through at once and the chute jams as the grains get **frozen** in place" (2000, p.31). Jamming transitions are quite a common **phenomenon**. It can be observed for ex. in traffic jams, or in stampedes at too narrow outlets in a theater or a stadium.

→ **Density (Critical)**

1803

JOINED

→ **System (Richly or poorly joined)**

1804

JUNCTION

→ **Adding junction**

1805

JUST NOTICEABLE DIFFERENCE¹⁾

The least quantitative **stimulus** that can be perceived by an **observer** or experimenter.

This is a very important notion for **systemics** and **cybernetics**, because, under the **threshold of perception**, we fall into the realm of **invisibility** and we may well incur into "ignorance of our own ignorance". As a consequence, we may fall prey to unsuitable **modeling**.

W. Mc CULLOCH writes that JND "... has been found in the middle range of **perception** to be roughly proportional to the size of the **stimulus**" (1974, p.6).

However, the JND **threshold** becomes lower for a trained **observer** of some specific kind of **phenomena**: Mc CULLOCH gives the example of the **Golden Proportion**, much more easily perceived by architects, sculptors and painters.

K

1806

K - STRATEGY^{1) - 2)}

A system's strategy that aims at having fewer, larger and higher **energy-using elements** whose **life spans** are long and rate of replacement low (adapted from R.N. ADAMS, 1988, p.134).

ADAMS explains as follows this **concept**, borrowed from **ecology**: "**Hierarchical structures** behave (according to) K-strategy: they are large but consume more **energy**" and "They take a longer **time** to come into being" (p.134).

K-strategy is better adapted in conditions of general **environmental stability**, where **elements** or **parts** are in less danger of individual destruction.

However, when systems constructed according to a K-strategy dissolve in **parts** due to some considerable environmental **disturbance** these **parts** "...often cannot sustain themselves and thus need to reorganize along different lines in order to survive" (Ibid).

In many cases, they are not able to do this: scattered **populations** close to extinction, imperial **structures** losing **control**, disorganized conglomerates are examples.

1807

KAM THEOREMS^{2) - 5)}

"KAM" is for the Russian mathematicians and physicists A.N. KOLMOGOROV, V.I. ARNOLD and J. MOSER. The theorems are about the **dynamics** near a **periodic** orbit. They show that for some **Hamiltonian systems** (i. e., practically **homeostatic**) affected by slight **perturbations**, there may exist numerous different **initial conditions** that may produce **quasi-periodic** movements, describable by convergent series, and corresponding to **toroidal attractors**: The **threshold of chaos** can be, or not, crossed.

ARNOLD showed that this applies, at least in some cases when **perturbations** are quite small, to POINCARÉ's **n-bodies problem**.

For **non-Hamiltonian systems**, in I. PRIGOGINE's words: "KOLMOGOROV" (K-) systems exhibit a complex **behavior** of individual **trajectories**, like exponential **divergence**, to the effect that no finite **algorithm** can reliably compute the motion of **phase points** sensibly faster than the **dynamics** itself. Systems of this kind include geodesic **flow** on surfaces with negative curvature..." (1986, p.5).

K-FLOWS

(Also named after KOLMOGOROV)

K-flows are characteristic of near-**chaotic systems**. J. CASTI writes: "Their **behavior** is at the limit of **unpredictability**, in that having even an infinite number of **measurements** of

where the system was in the past is of no help in predicting where it will be found next. K-flows are widespread among systems in which collisions between particles dominate the **dynamics**" (1990, p.288).

In synthesis, the borders between **ergodic systems**, **thermodynamically unstable** ones and **chaotic** ones are **fuzzy**.

→ **Baker transformation and LIAPOUNOV exponent**

1808

KHEPERA ROBOT

→ **Robot (Khepera)**

1809

KIN SELECTION⁴⁾

A **mechanism** leading to the constitution of social **groups** based on genetic **relationships**

This **process** is observed mainly, but not exclusively in insect societies.

W.D. HAMILTON showed that "... the total **fitness** of individuals was actually the sum of two different sources: a direct **component** stemming from an individual's reproductive effort and an indirect component stemming from the reproductive effort of relatives. The magnitude of the indirect component depends on the degree of genetic **relationship** to those relatives, and there are thus conditions under which it may pay to forgo reproducing yourself and instead assist in the rearing and defense of relatives". (J.T. COSTA, 1997, p.151)

COSTA observes: "...social **behavior** may have evolved independently several times, with varying **patterns** of gain and loss of particular social characteristics" (Ibid).

Socialization through kin selection implies other significant aspects as: **recruitment communication** (in insect societies, mainly through **pheromones**), **aggregation**, **patch** restriction and **boundaries** marking.

Similar **processes** are very probably at work in human societies. Archaic ones were generally based on specific forms of kinship. In modern ones one may wonder if **ideologies** or common interest do not substitute kin **selection** and be a new type of **aggregation** factor.

The importance of kin selection and the way it leads to wider and more complex social **behavior** have been explored by D.C. QUELLER (1985, p. 366-67)

→ **Meme; Memetics**

1810

KNOWLEDGE³⁾

"The result of **learning** and **cognition**, tested in practice (ideas, conceptions)" (UNESCO - UNEP Glossary, 1983, p.17).

Of course, many other definitions have been proposed. The UNESCO Glossary however adds significant comments: "Includes the **cognition** of real **objects** and **phenomena**, laws of nature

and society, **environmental** problems and the correct reflection of all this cognized **information** in the **process** of thinking" (ibid). Taking in account the following reflexions, bearing on the general conditions of knowledge, this is as good a general definition as any other.

H.von FOERSTER observes that there is "... an almost universal confusion in which "knowledge" is seen as a commodity, i.e. is identified with substance rather than with **process**... An educational system that confuses **learning** with the dispensing of goods called "knowledge" may cause some disappointment in the hypothetical receivers, for the goods are just not coming: there are no goods" (1974, p.21).

This view about knowledge thus enounced is notwithstanding generally unheeded by A.I. specialists who, in D. GREGORY's words, believe that:

"Knowledge is a commodity. We can trade it, teach it, learn it, remember it, represent it, discover it...

"Knowledge is distinct from its knower – just like **data** are distinct from computer disks;

"Knowledge is **sets** of true **facts** together with the **rules** for combining them;

"Knowledge can be reduced to **sets** of primitives – just like **matter** is ultimately reducible to fundamental particles" (1993, p.67).

For the practical application of these disputable views, which seem to confuse knowledge with simple **information**, or even mere unstructured collections of **data**, see hereafter T. ÖREN's **Knowledge's General Taxonomy**.

As an antithesis, D. GREGORY states "PASK's idealist axioms":

"Knowledge is a **process**, not a **state**. It is not "that which is known", but the **process** of knowing (alias observing, alias distinguishing).

"Knowledge consists in coherent systems of **relationships** that connect knowers with their world, not **facts** with each other, independent of their knowers... (note that the sky is not blue to insect eyes – But then who is to say that any concept of "sky" exists for an insect, to begin with).

"Primitivity is with respect to the knower, not the world: knowing that food satiates hunger is elementary knowledge for a small child. but very elaborate for a biologist" (1993, p.68).

In the same vein as von FOERSTER, D. BOHM and F.D. PEAT write: "Knowledge of reality does not therefore lie in the **subject**, nor in the **object**, but in the dynamic **flow** between them" (1987, p.67). In J.L. VULLIERME words: "The object of knowledge is the knowledge of the **object** by a local, and localized **observer**" (1990, p.151).

Knowledge is thus the result of a **recursive** transaction between an **observer**, already endowed with a basic cerebral **organization**, and reality and, consequently, supposes a perpetual readjustment of the internal **state** of the **sub-**

ject. This internal readjustment tends however to become more and more stabilized through **time**, due to the formation of **learning algorithms** (individually and socially conditioned).

Finally, in W. REEVES words, knowledge is: "...neurally incorporated and organized **information** (which) supplies us with a usable and lasting sense of the world" (of course, in our own terms) (1992, p.1102).

It is noteworthy to emphasize this opinion, based on the neurology of **communication**, in relation to some of the following entries which precisely accept in an implicit way the quite different notion of knowledge as something tangible that can be stored, located, transformed, etc... (This viewpoint proper to computer scientists should not be uncritically accepted outside of computer science).

As a collective cultural endeavor, I. PRIGOGINE observes that: "... the ideal of complete knowledge, which has haunted Western science for three centuries... is only meaningful for the limiting case of **stable dynamic systems**. The message of the **2nd law** is precisely that we are living in a world of highly unstable motions, to which the classical ideal does not apply" (1986, p.2).

In this sense, the complete and absolute knowledge ideal should be replaced by non-contradictory **coherence** in knowledge, submitted to constant **validation** through a **falseability process** "à la POPPER".

1811

KNOWLEDGE: a pragmatic and operative view^{1) - 5)}

It would be quite irresponsible to broach such a philosophical problem as knowledge in a short and superficial way, while it occupies the best minds since 25 centuries.

For our purpose, "knowledge" is that which allows complex systems to sustain themselves and to act.

From this pragmatic viewpoint, B. ZEIGLER states:

"A system "knows about "a **class** of **objects**, or **relations**, if it has an *internal representation* for the **class** which enables it to operate on **objects** in this **class** and to communicate with others about such **operations**.

"Thus, if a system knows about **x**, a **class** of **objects** or of **relations** on **objects**, it is able to use an internal **representation** of the **class** in at least the following ways: receive **information** about the **class**, generate **elements** in the **class**, recognize members of the **class** and discriminate them from other **class** members, answer questions about the **class**, and take in-

to account **information** about **changes** in the **class** members" (1986, p.15).

Such an internal **representation** is a **set** of more or less elaborated **models**, acquired through a **process** of **learning**. As shown by numerous experiments, somewhat similar **models** seem to be already present under rudimentary forms even in inferior animals.

This leaves open questions about the degree of **consciousness** that must necessarily go paired with knowledge.

1812

KNOWLEDGE ACQUISITION (Taxonomy of)⁵⁾

T.ÖREN propose the following – and quite general – taxonomy (1990, p.22):

see table below

All this seem quite similar for natural intelligent systems. "Changing **representation**" can be a tricky business, from the viewpoint of **simulation of concrete systems**.

Table: see entry **KNOWLEDGE ACQUISITION (Taxonomy of)**

Criteria for discrimination	Types of knowledge acquisition
Sources of input knowledge	
Exogenous	
Acceptance	Input Sensation
Detection	Knowledge detection Perception Recognition
Endogenous	
Generation of implicit input	Generation of Questions Hypotheses Alternatives Recognition of unstated, implicit or commonsense know- ledge
Anticipation of the future	Generation of anticipatory knowledge Anticipation of future values of inputs , parameters , structures
Processing of input knowledge	
Changing representation	Decoding
Filtering	Knowledge discrimination Selection Pattern recognition Regulation
Assimilation	Knowledge assimilation
Future knowledge processing	Building a passive knowl- edge base
ability of the system is not affected by acquired knowledge	
is affected by acquired knowledge	Machine learning

¹⁾general information

²⁾methodology or model

³⁾epistemology, ontology and semantics

⁴⁾human sciences

⁵⁾discipline oriented

1813

KNOWLEDGE ANALYSIS (Taxonomy of)⁵⁾

T.ÖREN makes the following **distinction** in his knowledge analysis, from the viewpoint of **machine** intelligence (1990, p.27).

see table middle column

The whole concept of knowledge *analysis* should be carefully considered, and very specially the idea of knowledge *decomposition*, which could easily throw the baby of interconnected **meanings** with the bath water of digital computerization.

1814

KNOWLEDGE (Analytic and Systemic)^{1) - 3)}

M. LIU synthesizes in the following tables the differences between both types of knowledge. (1989)

see tables below

1815

KNOWLEDGE as a control on behavior¹⁾

According to F. HEYLIGHEN, "Knowledge can be defined as the ability to choose adequate actions from the **repertoire**, where *adequate* means: securing the **survival** of the system within its **environment**. Knowledge *selects ac-*

Table: see entry **KNOWLEDGE ANALYSIS (Taxonomy of)**

Criteria for discrimination	Types of knowledge analysis
Finding composition (and/or) decomposition	Knowledge decomposition
Detection of elements	Lexical analysis Syntactical analysis Semantic analysis
Detection of meaning	
Characterization to enhance:	Knowledge characterization (pragmatic analysis)
Comprehensibility	Knowledge comprehensibility
Documentation	Annotation On-line Off-line Documentation On-line Off-line
Investigation Usability	Knowledge ventilation Knowledge usability
Referability	Knowledge base management
Modifiability	Knowledge modifiability

tions from the **variety** of potential **actions**, in the same way that natural **selection** selects by destroying inadequately behaving systems. The difference is that knowledge does not destroy

actual systems, it only eliminates *potentialities*. Knowledge can thus be defined as a substitute or *vicarious selector*, which internally represents – and thus allows the anticipation of – the selective **action** of the **environment** (see CAMPBELL, 1974)" (pers. com.).

Knowledge is, of course, subjective (i.e. proper to an **observer**) and thus merely **plausible**, which means that its adequateness cannot be totally guaranteed.

HEYLIGHEN makes another important point: "What distinguish knowledge from **control** in the more traditional sense, is that cognitive **control** does not depend on a specific, **fixed goal** that the system is supposed to achieve. The only, very broadly defined **goal** is **survival** of the **identity**..." (Ibid).

In other words, knowledge is a tool for **organizational closure**.

And: "Moreover, cognitive **control** is supposed to cope with a complex **environment**, and will in that way have to represent as much as possible features of that **environment** that are relevant to **survival**" (Ibid).

Here again, the practical results depend on the quality of the "maps" (KORZYBSKI) or the **models** (ASHBY).

Table: see entry **KNOWLEDGE (Analytic and Systemic)**

1. Levels and Nature of Knowledge

Level	Analytical Approach	Global Approach
1. Construction of the object of study	Determination of its permanent properties Data, Informations	Delimit the system under study. Define convenient research tools
2. Description of relations and, or transforms between objects	Universal and permanent laws	Definition of the observables. Elaboration of a specific language if necessary. Use of conceptual tools
3. Methodology . Enounce means obtain valid knowledge	Normative methods applicable to all situations Selection of alternative methods in accordance with objectives	Research and action specific to the situation under study. Heuristics
4. Reflexion about the foundations of knowledge	Adoption of a unique logic. Formalization of a normative epistemology	Reflexion on logics. Research and explication of paradigms underlying the knowledge mode being used.
5. Critical epistemology		Epistemologic debate. Creation of new paradigms .

2. Orientation of the two **modes** of knowledge

Deterministic analytic approach	Global approach
Obtaining the general and permanent properties of classes of objects	To know the general and the specific of complex systems or situations
Be able to predict with the maximum certainty the evolution of their transformations .	Locate evolutions in history Predict conditionally
To control the evolution of the objects and to produce artefacts .	Defining heuristics to understand and also act in singular and unique situations . Taking in account indeterminacy . Steer open processes . Enhance autonomy . Develop learning processes

1816

KNOWLEDGE BASED SYSTEMS: An evaluation^{3) - 5)}

Peter J. DENNING writes:

"Knowledge based systems (KBSs) are founded on the assumption that an expert works from a complete theory of the **domain**. Once a theory is articulated as a **set** of **rules** and stored in a database, the superior power of the computer can draw inferences much faster than the expert..."

What is thus not accomplished "...cannot be blamed on a lack of computer power, **memory**, research effort or cooperation of experts. An explanation gaining credence is that experts themselves do not work from complete theories, and much of their expertise cannot be articulate in **language**" (1991, p.495).

It remains quite doubtful if any complete theory can be obtained of any specific **domain**. This limits somewhat the KBS modeling **reliability**, because computer treatment needs an **algorithm**, which does not incorporate new "hunches" or renewed **intuition**. However KBSs can be progressively perfected.

In any case: "Education that equates expertise with models can inhibit the development of good judgement" (Ibid.).

1817

KNOWLEDGE (Construction of)³⁾

The construction of knowledge is basically the acquisition of perceptive and conceptual **invariances**, "...with which to explore, order, and predict experience" (E von GLASERSFELD, 1976, p.116).

According to von GLASERSFELD: "If we accept the notion that rational knowledge involves the generation and use of **invariances** and **rules**, we cannot help asking how these **invariances** are generated and what they concern" (p.119). This is the "prime mover" concept of **constructivism**.

The subject was also broached early by J. PIAGET, who wrote in his "Epistémologie génétique": "Knowledge should not be conceived as pre-determined, neither within the internal **structures** of the **subject**, as they result from an effective and continuous **construction**, nor in the pre-existent characters of the **object**, since they become known only through the necessary mediation of these **structures**" (1970, p.5).

He also stated: "Cognitive **processes** appear then simultaneously as a result of the organic **self-regulation** of which they reflect the basic **mechanisms**, and as the most differentiated organs of that **regulation** within the **interactions** with the **environment**" (1967, as quoted by I. PRIGOGINE, 1973 b).

It is somewhat difficult to harmonize these views with the **autopoietic** view of the **observer** endowed with perceptual and conceptual **organizational closure**. This compiler believes that the physiological and nervous **capacity** to construct knowledge is innate, i.e. organizationally closed, but that it gives the **subject** the potential for **learning** and, through **learning**, create a perceptual and conceptual **structure** that ends up more and more **autopoietic**. Such a view is consistent with the **progressive stabilization** – and eventual **sclerosis** – of personality and worldview.

From a practical viewpoint M. DODDS and G. JAROS make the following **distinctions**: "**Information** is *descriptive*; it is contained in answers to questions that begin with such words as What, Which, Who, How many, When and Where. Knowledge is *instructive*; it is conveyed by answers to How-to questions. **Understanding** is *explanatory*; it is transmitted by answers to Why questions.... (while) **understanding** presupposes knowledge and **information**... **information** presupposes neither knowledge nor **understanding**" (1994).

This seems quite extreme. Information presupposes at least some **frames of references** if it is to be more than pure **data**.

Table: see entry **KNOWLEDGE DISSEMINATION (A taxonomy of)**

Criteria for discrimination	Types of knowledge dissemination
Based on existence of explanations	
Without explanations	Primary output Access to knowledge bases (data base, model base, rule base, goal base...) Output is generated/transformed by the system Auxiliary output Help facility Guidance Certification
With explanation	Explanation Advice
Based on knowledge channels	
Fixed channels	Coupling Hierarchical Nested Time-varying
Flexible channels	Message passing
Based on number of receiving	
objects/systems	Knowledge transmission
One-to-one	Selective knowledge dissemination
One-to-some	Knowledge broadcasting
One-to-many	Knowledge posting (bulletin board, black-board)
On a common area	Knowledge distribution (journal, lecture notes)
On individual areas	

1818

KNOWLEDGE CONSTRUCTION (Physiology of)^{3) - 5)}

R. FISCHER synthesizes the successive stages of knowledge construction in the **brain** (1992, p.211).

A "primary **repertoire**" is formed "between the 10th to 18th week of gestation... (when) the formation of neurons accelerates, and a fierce competition for neurons to *connect* with other neurons and with sensory cells can be observed. Those who could not link up, die off. These **interconnections** are formed during **development**, prior to experience, and there is evidence for extensive **variance** of **connectivity**, even in genetically identical animals.

"A secondary **repertoire** is in the making during *postnatal experience*: **selection** among diverse preexisting groups of **cells** accomplished by differential modification of synaptic strengths or efficacies *without change in connectivity pattern*. **Responses** of neural **populations** are significantly influenced by similarities between present and past constellations of sensory **signals**. **Perception**, **memory**, **learn-**

ing are consequences of selective **amplification** which leads to increased speed or strength of selected **responses** when similar **patterns** of **stimulation** are repeated"...

"It takes then many years of **environmental** exposure until a third, a more global, **problem solving repertoire** is acquired from the **brain's** self-experience that we have in the mind. This knowing system can generate alternatives that subserve **goal seeking**, alternatives that are selected by the **environment** for **fitness**".

→ **Connectivity**; **HEBB's rule**; **Reinforcement**

1819

KNOWLEDGE DISSEMINATION (A taxonomy of)⁵⁾

The last table in ÖREN's stimulating study of so-called "knowledge" in fact in close relation to artificial **intelligence** in **software** engineering is about **outputs** and **transmission** (1990, p.42).

see table middle column

1820

KNOWLEDGE (Ecology of)³⁾

"The study of **patterns** of **interrelationships** among the various "species" (**subsystems**, **subsubsystems**, etc...) or **fields** and subfields of knowledge" (J.W. CLARK, 1972, p.168).

CLARK, who proposed this conceptual frame, and a corresponding project of "Degree Program in G.S. Studies" emphasizes the necessity to:

"a) preserve the condition of dynamic balance between the "species" and their **environment**;

"b) optimize the overall, symbiotic fruits of **synergistic interactions** among them" (Ibid).

In fact, ecology of knowledge should also introduce other items as, for example, cybernetic and systemic **models** and concepts, as well as some new mathematical tools (**graphs**, **fractals**, **catastrophes**, **chaos**, etc...), all of which permit to interconnect **fields** and subfields in a significant way.

1821

KNOWLEDGE ENGINEERING⁵⁾

"Part of **artificial intelligence** research concerned with the development of **expert systems** as well as with the development of the necessary **methods** and tools" (E. BUCHBERGER, 1987, p.31).

E. BUCHBERGER adds that the role of the knowledge engineer is to build the knowledge base of the **expert system**, starting from the expert's knowledge to create **representations** of the same, compatible and intelligible within the **expert system**, and to introduce in it an in-

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Table: see entry **KNOWLEDGE GENERATION (A taxonomy of)**

Criteria for discrimination	Types of knowledge generation
Knowledge generation from real world	Observation Experimentation Instrumentation
Knowledge generation using a model based on: Type of behavior	Simulation Trajectory Structural
Type of change	Continuous Discrete Process interaction Discrete event Activity scanning Discrete arithmetic Finite state machine Quasi continuous Discontinuous Combined Catastrophic
Type of determinism	Deterministic Stochastic

ference engine, i.e. a device apt to reach conclusions by combining the **elements** of the knowledge base in accordance with definite **rules** (**Inference rules**) (ibid).

1822

KNOWLEDGE EVALUATION (Taxonomy of) ⁵⁾

T.ÖREN establishes that taxonomy as follows (1990, p.31):

see table middle column

This evaluation taxonomy brings about a tool for a very much needed self-criticism of **modellers**.

1823

KNOWLEDGE GENERATION (A taxonomy of) ⁵⁾

T. ÖREN offers the following proposal of taxonomy of knowledge generation by experiential techniques (1990, p.37)

see table left column

Table: see entry **KNOWLEDGE EVOLUTION (Taxonomy of)**

Criteria for discrimination	Types of knowledge evaluation
Intrinsic evaluation of Knowledge	Knowledge reliability Accuracy Completeness Correctness Integrity Consistency of representation Certification of representation
Knowledge base	Knowledge base reliability Completeness Consistency Security
Functioning of a system Knowledge processing action	Diagnosis Correctness of knowledge processing Robustness of knowledge processing
Knowledge processing action of: Self On current action On past action Other system(s) On current action On past action	Introspection Retrospection Monitoring Testing Postmortem analysis
Relative evaluation of knowledge with respect to: Perceived reality	Realism Correctness Validity Verification Qualification
Goal of knowledge processing Range of applicability	Relevance Adequacy
Another knowledge of: Different entity under the same condition Same entity under different condition	Comparison Sensitivity analysis (sensitivity of the entity to the conditions)

It is rather curious that ÖREN did not introduce "chaotic determinism" in his taxonomy.

1824

KNOWLEDGE GENERATION by nonexperimental techniques (A taxonomy of) ⁵⁾

This is ÖREN proposal (1990, p.39):

see table right column

Again, **chaotic determinism** seems to have its place between **determinism** and **randomness**.

These two last tables are very enlightening about the various ways we construct knowledge. Between **induction** and **deduction**, possibly as a form of **induction**, could we not introduce **connection** which seems closely related to **learning** in natural and artificial **intelligence** in systems.

Table: see entry **KNOWLEDGE GENERATION by nonexperimental techniques (A taxonomy of)**

Criteria for discrimination	Types of knowledge generation
Using numerical methods , which can be Deterministic	Computation Optimization Prediction (anticipation)
Stochastic Model is deterministic Model is stochastic	Monte Carlo simulation Statistical inference

KNOWLEDGE GENERATIVE (Taxonomy of) ⁵⁾

T.ÖREN proposed what he calls a "paradigm for artificial **intelligence** in **software** engineering" (1990, p.1-55). The eleven following tables reproduced from his paper, also constitute however an interesting challenge in reference to our **understanding** of **brain intelligence**. ÖREN first characterizes the intentions, objects (relations), conditions and ways useful in knowledge generation (p.20).

see table next page left column

It would be interesting to consider this framework from the viewpoints of brain neurology and classical philosophies.

The idea to **reduce** problems should be carefully scrutinized.

1826

KNOWLEDGE (Implicit) ³⁾

The existence of implicit knowledge as a substratum for explicited one has been explored by M. POLANYI (1966).

Table: see entry **KNOWLEDGE GENERATIVE (Taxonomy of)**

Criteria for discrimination	Types of generative knowledge
Intention to generate knowledge	Goal (intention) Subgoal Subgoal (problem reduction)
Objects/relationships used in knowledge generation	Model/design Computational model Optimization model Dynamic model (for simulation) Inference model Rule Decision table Script Frame Slot Semantic net And/Or graph ISA hierarchy Qualitative model Statistical- inference model
Condition to generate knowledge by :	Knowledge generation frame
Experiencial techniques	Experimental frame to generate model behavior observe real-world behavior .
Non-experiencial techniques using Inferencing Optimization Computation	Inference frame Optimization frame Computational frame
Ways to generate knowledge	Schematic knowledge Plan Schedule Agenda Schema Algorithm Procedure Method Heuristic

The establishment of spontaneously organized **connections** among scattered "**bits**" of **information** seems the only way to start to explain how new concepts and theories can appear suddenly in the mind (as testified for example by KEKULE, GAUSS, POINCARÉ, VENDRYES and many others).

The most recent experiments with **neural networks** offer an interesting insight about how this could happen in the **brain** (M. BODEN, 1991, p. 25 – D. GERNERT, 1994, p.128).

A. KOESTLER concept of **bisociation** of **matrices** could be another way to understand how new explicit **knowledge** comes into existence.

Genesis of mental and conceptual **complexity** seems thus to be probably a **phenomenon** of **emergence** through combination. As such, it is very significant for **systemics**.

Table: see entry **KNOWLEDGE IN A COMPUTER (Input and Output of)**

Types of input/output	Additional characteristics	
	Criteria	Characteristics
Numerical	Base Nature Type Precision	Decimal, binary , octal, hexadecimal, etc. Scalar, vector, matrix tensor Integer, real complex Single, double, variable
Textual	Dimension Nature	1-dimensional (string) 2-dimensional (page reader, printer) Natural language processing, text understanding, abstracting, synthesizing
Graphical	Dimension Movement Color	2-dimensional 3-dimensional Still Moving Monochrome Color
Audio	Nature	Sound Speech recognition
Tactile	Nature	Pressure (detect, induce) Vibration (detect, induce) Texture (detect, induce)
Chemical	Nature	Taste (discriminate, synthesize) Smell (discriminate, synthesize)
Other types of signals coming from sensing devices or going to control devices	Nature	Velocity (linear, angular) Acceleration (linear, angular) Jerk (linear, angular) Force, torque Strain Flow rate Humidity Radiation (heat, radioactivity)

1827

KNOWLEDGE IN A COMPUTER (Input and Output of)

(Types of input and output knowledge of a computer **program**)⁵

see table above

1828

KNOWLEDGE (Law of requisite)^{1) – 2)}

"In order to adequately compensate **perturbations**, a **control** system must "know" which **action** to select from the **variety** of available **actions**" (F. HEYLIGHEN, 1992a, p.9).

F. HEYLIGHEN comments: "This principle reminds us that a **variety** of **actions** is not sufficient for effective **control**: the system must be able to (vicariously) select an appropriate one".

Such an ability seems to be basically a matter of **learning**, possibly at least at the beginning by **trial and error**. Later on, a **repertory** of adequate **responses** accumulates and the system becomes progressively abler to adapt itself to a great **variety** of **disturbances**.

The construction of the **repertory** is obtained by reducing the internal **redundancy** of the system, in accordance with the **order by noise** principle.

1829

KNOWLEDGE LOCATION (Taxonomy of)⁵⁾

T.ÖREN describes tactics and techniques of knowledge location in the intelligent **machine**, in the following way. The similarities with **brain's activity** confronted with the same problem should be usefully researched (1990, p.25).

see table next page left column

1830

KNOWLEDGE ORGANIZATION (Taxonomy of)⁵⁾

T.ÖREN proposes the following ways for organizing knowledge (1990, p.34):

see table next page middle column

¹⁾general information²⁾methodology or model³⁾epistemology, ontology and semantics⁴⁾human sciences⁵⁾discipline oriented

Table: see entry **KNOWLEDGE LOCATION**
(Taxonomy of)

Criteria for discrimination	Types of knowledge location
Knowledge location without trace	Search - Breadth-first - Beam - Depth-first - Forward - Backward - Bidirectional - Pathrank order - Blind Goal-directed Data-directed - Hill-climbing - Optimal Heuristic - Best-first
Knowledge location with trace	Tracking - Backtracking - Chronological - Dependency-directed - Intelligent - Sidetracking - Tracing

1831

KNOWLEDGE (Principle of incomplete)³⁾

"The **model** embodied in a **control** system is necessarily incomplete" (F. HEYLIGHEN, 1991a, p.9).

HEYLIGHEN, who enounces this principle, sees it as a consequence of various other limitative principles which came to the fore during this century:

- W. HEISENBERG's **uncertainty principle**
- A. EINSTEIN's **relativity principle** ("of the finiteness of the speed of light", implying that the moment the **information** is registered, it is already obsolete to some extent).
- H. SIMON's principle of **bounded rationality**, "stating that a **decision** maker in a real world **situation** will never have all **information** necessary for making. an optimal **decision**"
- L. LÖFGREN's principle of the **partiality of self-reference** "implying that a system cannot represent itself completely, and hence cannot have complete **knowledge** of how its own **actions** may feed back into the **perturbations**" (p.10).

1832

KNOWLEDGE (Shared)²⁾

The basic knowledge distributed within a **network** of cooperating **elements** or **agents**.

In **networks** of **agents** endowed with such a shared knowledge – necessarily including **communication codes** - **consensual decision making** and tasks performing is possible.

As stated by M. BORILLO this applies to ergonomics or in psychosociology as well as to

Table: see entry **KNOWLEDGE ORGANIZATION**
(Taxonomy of)

Criteria for discrimination	Types of knowledge organization
Knowledge exists in one file	Ordering relations - Ordering - Partial - Linear (simple) - Well-Transfinite
Outcome of ordering	Sorting
Putting knowledge in sequence	Scheduling
With respect to time	Concurrency
Putting knowledge in groups	Synchronization
No hierarchy	Classification (assortment)
	Categorization (labeling, clustering, prioritization, Tiebreaking)
Hierarchy	Hierarchy (taxonomy) building
Knowledge exists in two files	Merging
outcome is in: one file	Merging with selection
several files	Pairing (matching)

logical and computing formulations for **simulation** of cooperative **behavior** in man or in social insects (1993, p.1129).

It is also the corner stone of the **activity** of collaborating **automata** in **networks** (see J. ERCEAU & J. FERBER, 1991).

1833

KNOWLEDGE (Tacit infrastructure of)³⁾

D. BOHM and F.D. PEAT write: "Some of our most valuable skills exist in the form of... tacit infrastructure of knowledge. A child, for example, spends long hours with a bicycle before suddenly learning to ride. Yet, once the new skill is acquired, it never seems to be forgotten" (1987, p.20).

In other words, we acquire **behavioral algorithms** and mental **autopoiesis**, by back-propagation (i.e. automatic self correction), by automatic **reinforcement** of successful **behavior** or by normative **feedback**.

This is somehow recognized even by J.J. GIBSON, who writes: "Knowledge of the **environment**, surely, develops as **perception** develops, extends as the **observers** travel, gets finer as they know to scrutinize, gets longer as they apprehend more **events**, gets fuller as they see more **objects**, and gets rich as they notice more **affordances**" (1986, p.153).

In short, it becomes better as we enrich – and learn how to enrich – our sensorially ob-

Table: see entry **KNOWLEDGE SELECTION**
(Taxonomy of)

Criteria for discrimination	Types of knowledge selection
Selection without conflict	Decision (single or multi-criteria)
Based on value-free criteria	Value-free decision Description - Interpretation - Explanation - Deductive explanation - Statistic generalization - Teleological explanation - Motivational explanation - Functional explanation - Genetic explanation Prediction Data-directed prediction Scenario writing Trend projection Model-directed prediction Delphi technique Simulation - Quantitative - Qualitative Growth analogy - Correlation Normative decision
By data-directed technique	Evaluation
By deductive inference	Prescription
By trend extrapolation	
By model-directed technique	Agreement

tained **data**. Knowledge becomes in this way a capacity for recognizing **similarities** with that which one is already equipped to recognize, and a capacity to blow up accordingly the **autopoietic frames of reference** from inside out.
→ **Knowledge (Implicit)**

1834

KNOWLEDGE (Taxonomy of Factual)⁵⁾

T. ÖREN proposes the following taxonomy (1990, p.18) *see table next page left column*

See hereafter ÖREN's further taxonomies of knowledge generation, acquisition, location, analysis, selection, evaluation, organization, transformation and dissemination.

The whole set is a quite complete credo for specialists in computer operation on collected **data** and **information**, which may in effect generate knowledge *in thinking brains*.

Criteria for discrimination Types of factual knowledge

Sources of knowledge
 An existing system
 An hypothetical system
 A system that will exist
 A model

Real-world knowledge
 Hypothetical knowledge
 Design specification
 Behavior of a model

Experimental evidence for knowledge
 Observed knowledge
 Real-world knowledge
 Simulated knowledge
 Inferred knowledge
 Asserted knowledge
 Conjectured knowledge

Truth value of knowledge
 Knowledge
 Hypothesis
 Belief

Scope of knowledge
 Specific knowledge - fact
 Numerical fact
 Nonnumerical fact
 Attribute
 Relationship
 Universal knowledge
 Rule (conditional fact)
 Principle
 Law
 Axiom

Time indexation of knowledge

Knowledge is given as a time-indexed sequence of values of variables structures of a system or a model

Trajectory behavior
 Structural behavior

No time indexation Point behavior

1835

KNOWLEDGE (Taxonomy of the ways of generation, representation and processing of)²⁾

T.ÖREN did elaborate a general taxonomy of knowledge representation and processing (1990, p.1-55).

His general focus is on **informatics** and computer processing and his vocabulary is, accordingly, more or less specialized. This terminology should be carefully evaluated in comparison with its commonly accepted **meanings**.

Moreover his concept of knowledge is very close to the concept of **information** and quite close to the **meaning** given to the word "knowledge" in **expert systems**. This is practically in frontal contradiction with H.von FOERSTER's view: Knowledge is *not* a commodity.

However, it is also interesting to ponder ÖREN's ideas from various different viewpoints, as for example:

- Similarities and differences between natural and **artificial intelligence**;
- **Brain organization** and neuro-chemistry;
- Artificial and natural **neural nets** and **connection machines**;
- **Learning processes**;

Here is a list of ÖREN's taxonomic tables, reproduced, in *logical* order:

Taxonomy of:

- factual knowledge
 - knowledge generation
 - knowledge acquisition
 - knowledge location
 - knowledge analysis
 - knowledge selection
 - knowledge evaluation
 - knowledge organization
 - knowledge transformation
 - knowledge generation by experimental techniques
 - knowledge generation by nonexperimental techniques
 - knowledge dissemination

 - **Machine-learning system** (Elements and basic functions of)

1836

KNOWLEDGE SELECTION (Taxonomy of)⁵⁾

T.ÖREN establishes this taxonomy as follows: (1990, p.28).

see table page 329 right column

One wonders about *value-free criteria*. Does such thing really exist? Moreover, which are the **criteria** to establish **criteria**? However, this general taxonomy of **selection modes** represents an important advance, compared with the naïve ways frequently observed in practice

ÖREN himself observes in relation to **value free decisions** that "since **observations** and inferences can be erroneous, **descriptions** have to be selective and must rely on interpretations." (p.29)

In other words, no **decision** is perfectly objective and "aseptical".

1837

KNOWLEDGE TRANSFORMATION (A taxonomy of)⁵⁾

T.ÖREN **classification** of the various possible transformations of knowledge is as follows (1990, p.35)

see table right column below

1838

KNOWLEDGE UNIT²⁾⁵⁾

M. KALAIDJIEVA describes as follows the "knowledge" (2001, p. 12)

"A knowledge unit (KU) in the **context** of generating new scientific knowledge is a piece of text in natural **language** presenting a novelty-invented new, or old but modified knowledge- precisely enough to communicate it to other individuals, compact enough to fit in a volume like precisely abstracts of scientific articles, or volume of reports, as it is usual nowadays, independent of context relatively to intro-

Table: see entry KNOWLEDGE TRANSFORMATION (A taxonomy of)

Criteria for discrimination	Types of knowledge transformation
Change the representation	Reformatting Decoding Encoding
Change the scope Increase within: the same domain	Rescoping Elaboration Generalization Descriptive Conjunctive
several domains	Abstraction Association
Decrease	Specialization (scope reduction)
without alteration	Focusing Attention focusing
with alteration	Simplification Pruning Condensing (summarizing)
Modify	Tuning Refinement

ductory **descriptions**, explanatory repeating of former **limits** of knowledge or surveys, details of proof with or without formulae, pictures, tables, etc".

1839

KNOWLEDGE UNIT (Methodological scientific)²⁾⁵⁾

M. KALAIDJIEVA writes (2001, p. 120)

A methodological scientific knowledge unit (MESKU) is a knowledge unit directly involved in technology of generating new knowledge and comprises statement(s) of new problem(s), experiment(s), hypotheses, law(s), **concept**(ion)(s), invented **methods** and **tools** and some other less significant like **description** of the problem **situation**, subject of research interest, etc.

1840

KNOWLEDGE UNIT (Multimedia)²⁾⁵⁾

M. KALAIDJIEVA writes (2001, p. 120)

"A multimedia knowledge unit in the **context** of **management**, innovation, research and **education** involvement is any human knowledge presentation, as details of **description**, proof, formulae, tables, sound, picture or drawing, etc. It has the quality of novelty, if it was designed for the first time by somebody"

1842

KONDRATIEFF CYCLE²⁾ - 5)

A more or less **cyclical evolution** of about 50 to 60 years discovered in economy by N.D. KONDRATIEFF.

This Russian economist published several papers on the topic from 1922 to 1928. The reality of the KONDRATIEFF **oscillation** seems now well established, even if there is some **fuzziness** about the **phenomenon**.

The subject has been reviewed recently by K. DE GREENE, who writes:

"The following would appear to be, systems theoretically, the necessary and sufficient conditions for the generation of the KONDRATIEFF phenomenon:

"1) The older system-field evolves or is driven **far-from-equilibrium** into a **domain of instability** (e.g. by overproduction of capital), and powerful forces try to restore the system to **equilibrium**. Temporary **steady-state** is lost.

"2. At **critical distance of levels**, system **evolution** may bifurcate along alternate pathways (e.g. toward a stock market crash).

"3. **Fluctuations** or mutations stochastically may occur (e.g. an emerging **paradigm of knowledge** or a technical invention).

"4 **Deterministic nonlinear interaction laws** permit **positive-feedback-mediated autocatalytic** and cross-catalytic **growth of fluctuations** into **nucleations** (e.g. an optimistic **group** in a **population**)

"5. The large **sociotechnical system** or **environment** attempts to damp the **growth of the nucleation**, and **conflict** arises (e.g. between older and newer way of organizing work)

"6. The **nucleation** triumphs, and system **evolution bifurcates** along its pathway, producing a new, irreversible **self-organization** that takes over the qualitatively changed system-field (e.g. a new **dominant technology**).

"7. **Processes** 1-6 repeat themselves, producing cascades of **bifurcations** and **structural changes** (e.g. technological **change** impacting **organization design**, in turn impacting economic **growth**)" (1988, p.291).

DE GREENE gives also a more formal interpretation of the KONDRATIEFF phenomenon and writes: "With certain simplifying assumptions (e.g. with regard to potential **functions**), **systems dynamics** and **catastrophe theory** can fit nicely into the broader framework of **dissipative structure theory**" (p.292).

see figure below

Another author who extensively researched the **long-waves** subject in economy and other fields is F. MEYER (1954 and 1974).

The KONDRATIEFF quasi-cycle seems to be an **envelope curve** for **cycles** of lesser **periods**. In DE GREENE's words: "The economic long **wave** (my "Kondratieff **cycle-structure**") is an **order parameter**" (1994, p.13). Its imperfect regularity reflects probably somewhat conflicting **determinisms** of various factors which act simultaneously and produce a global **chaotic determinism** that does not anyway become **dominant**.

DE GREENE also considers the possibility to develop a theory of KONDRATIEFF **waveforms** as **dissipative structures**, in accordance with PRIGOGINE's opinion that all **self-organizing systems** go through **cycles** of becoming, growing, changing and decaying (see G. NICOLIS & I. PRIGOGINE, 1977).

For a review of **forecasting** in KONDRATIEFF's cycle terms, see K. DE GREENE (1993, p.41-55).

An intriguing possibility would be the existence of a similar (or still longer **period**) **cycle** in the **evolution of ecosystems** and **social systems**. A systemic inquiry in these **fields**

could be rewarding. P. SOROKIN's now nearly forgotten (and somewhat shaky) investigations in historical **cycles** could possibly be reconsidered in such new terms.

→ **Self-similarity in the WEIERSTRASS function**.

1843

KÜPPERS MATRIXES²⁾

A series of successive and evermore complete interaction matrixes between a number of the most important systemists and cyberneticians, established by Günther KÜPPERS of Bielefeld University (Heinz von FOERSTER and Monika BRÖCKER, 2002, p. 268-69)

The matrixes impressively show the progressive **integration** of the system-cybernetics field through evermore complex and active reciprocal influences of the most innovative researchers in Physics, Chemistry, Ecology, Biology, Psychology, Information Theory, Philosophy and Systems and Cybernetics proper. They cover four successive periods: 1965-69; 1970-74; 1975-79 and 1980-83.

The matrixes are based on citations indexes. It would be important to further extend the matrixes and include new researchers for the successive subsequent periods of five years. the appearance of new people (for ex. THOM, E. LORENZ, BAK) and new concepts (**fractals**, **self organized criticality**, **apoptosis**, etc.) This is certainly a new step toward a more complete integration of the **transdisciplinary** framework.

L

1844

LABEL²⁾ - 3)

A symbolic device – generally spoken, written or drawn, that is used to represent something.

A. KORZYBSKI insisted much on the correct use of labels (1950). To begin with, **identification** of the thing labelled and the label should be carefully avoided. The label is not the thing and their confusion could bring very serious semantic, psycho-sociological and even practical problems. According to KORZYBSKI, the importance of the label is in its **meaning to us**, because it produces **reactions** (**semantic**, **psychological** and, in some cases, even **biological**) **in us**.

We should also take good care to avoid confusing labels of different **levels of abstraction**. KORZYBSKI showed with his **structural differential** (see Fig. p.331) that what is commonly known as an "**object**" is already a labelled **abstraction** of low level, synthesized through simplifications from the inexhaustible collection of characteristics of a "something there outside". However, the **abstraction process** does

Figure: see entry **KONDRATIEFF CYCLE**

From K. DE GREENE: 1993, p. 291

not stop there, as shown by the following example: This is "Kuki" (level 1); she is my "bas-set hound" (level 2); i.e. a "dog" (level 3); i.e. a "canine" (level 4); i.e. a "mammal" (level 5); i.e. a "vertebrate" (level 6); i.e. an "animal" (level 7); i.e. a "living being" (level 8). Every higher level covers more "objects" ... but that which is gained in generality is lost in specificity.

We finally reach the totally **abstract level** and create the label "life", open to much scientific and even ideological argument. Obviously, the whole of **systemics** is a labelling undertaking, a fact that should never be forgotten: The system is not identical to that "something there outside"

1845

LANDSCAPE²⁾

The global **space-time** wherein a system may seek better, or the best possible **fitness** conditions.

This is a more or less metaphorical **description** used by St. KAUFFMAN for the general study of the **fitness** conditions of biological systems (1993, Ch.2 to 4). He writes: "**Adaptive evolution** in real **populations** is necessarily a **search process** driven by mutation, recombination, **drift**, and **selection** over either fixed or deforming **fitness** landscapes" (p.95). However such landscapes can be mathematically modeled (p.95-120).

Landscapes can be more or less rugged, which means that a number of different **situations** can exist, offering variable **fitness** conditions. Very rugged landscapes imply separated islands of strong **stability** from which a system cannot easily escape, as it is in a nearly **frozen states**. Shallow landscapes imply the opposite conditions.

A single system is normally best adapted (**fit**) to a specific **space-time situation**, and may lose **fitness** if the **situation** changes too much for its **adaptive** capacity.

A **population** of some **class** of systems has the potentiality to globally adapt to changing **situations** by mutations and the search for better spots within the landscape.

This concept could be important for managers or leaders of **human systems**, seeking a better **understanding** of the evolving **fitness** conditions of their charge.

1846

LANDSCAPE (Epigenetic)

→ Epigenetic landscape

1847

LANGUAGE^{2) - 3) - 4)}

(Language being a very intricate concept, various definitions are given, all synthesized from numerous different sources)

1. A **set of elements** (pulses, gestures, **signs**, words, **symbols**, etc...) that can be combined through syntactical **rules** in order to form significant **associations**.

2. The **subset** of all the possible meaningful combinations that can be formed from a **set of signs**.

3. A **set of signs** with more or less commonly admitted, or coded **values** that can be used for the **communication** of **messages** between **senders** and **receivers**.

L.A. ZADEH, in turn, gives an equivalent but more formal definition: "A language *L* may be viewed as a correspondance between a **set** of terms *T* and a universe of discourse *U*" (1973b, p.33).

Any language must be a **set**, generally of quite numerous **signs**, given communicative **value** by coherent combinatory **rules**, shared by the **communicators**. As such, it can be considered a very general, extended and *open*, i.e. evolving **code**. E.von GLASERSFELD specifies that "These **signs** must be **symbols**, i.e. linked to **representations** (Symbolicity). Therefore they can be sent without reference to perceptual instances of the items they designate, and received without "triggering" a **behavioral response** in the **receiver**. As **symbols** they merely activate the connected **representation**" (1988, p.58). The word "tiger" does not normally induce an escape **reaction**, except in some quite specific **contexts**.

As to the **rules**, if they are to be **generative**, they must however introduce limitations, i.e. **constraints** to such **combinatorics**, otherwise it would not be possible to **construct** any specifically *meaningful* combinations.

The **rules** must define the **syntactic**, logical and **semantic constraints** of the language.

If these ordered **elements** are to be useful for any type of **communication**, they must be perceived and understood, in order to permit communicable **descriptions**. (H. PATTEE, 1977, p.262). This is obtained through the **coordination** of all **rules** within a **code** including their complete specifications.

P.Y. RACCAH thus describes the conditions for the understanding of which is transmitted:

"The first hypothesis postulates that the **meaning** of a sentence (or other expression of a natural language) can be described as a **set** of instructions for the possible interpreters, which state how they are supposed to *build* the significances of the possible utterances of that sentence, using their belief, **knowledge** and points of view about the **situation** of utterance. According to the second hypothesis, these instructions are concerned at least partially, with the point of view required in order to be able to interpret the possible utterances of that sentence. The third hypothesis postulates that these points of view can be described using gradual **fields** (topical fields), monotonic relations between those **fields** (topoi) and **con-**

straints of those **fields** and relations (topical **constraints**). Finally, according to the fourth hypothesis, the words of a natural language are conventionally associated to topical fields, and/or topical **constraints**; these **associations** are claimed to be responsible for the fact that the use of such or such word reflects an **ideology**, a belief or, simply, a particular **competence**" (1993, p.1245).

As to **perception**, it depends on the physiological characteristics of **senders** and **receivers**. For example, human beings do not perceive infra-red or supersonic waves, at least in a direct way, and thus cannot use them as **elements** of a language.

As to common **understanding**, it is based on the **knowledge** by **receivers** as well as **senders** of a *shared code* that must be learned: a **message**, correctly sent in Russian cannot be understood by someone who does not know Russian. This is the **meaning** of "meaningful".

The **codes** are the **syntactic rules** alluded to. They are needed to introduce **constraints** within the **set of elements**: it is obvious that not every **element** should be allowed to interconnect with every other in any **random** way, as such an undefined arrangement would be totally meaningless and could not carry any **information**. This is also the reason why the second definition considers the language as a **subset**. For example, with the latin alphabet, it is perfectly possible to construct different languages, by selecting different **rules**.

It should be taken in account, however that the **rules** may vary in time, as for example from Latin to Spanish, Italian or French.

On the other hand, as no language is a saturated **set of interconnections**, **rules** can be used as an **algorithm** for creating new combinations, corresponding to new **situations** and necessities.

In R.M. SNOW words: "Language cannot stand alone. It can only be understood in terms of a complex **relationship with action**" (1993, p.146).

Moreover, any **element** becomes **context dependent** within the language, because it can be used in quite a number of different **contexts** and, just as an atom within a molecule, acquire a **positional value**.

Ch. HENRY states it in the following way: "...language... is an aggregate of systems that taken together create an illusive, polysemous **context**. **Truth** cannot be fixed in such an **aggregate**" (1992, p.696).

As to the social character of language as a **communication** means, R. ACKOFF and F. EMERY (1972) describe it as: "A **set of signs** as well as instructions for their use such that (1) the **signs** can be produced by purposeful individuals; (2) the **signs** are semantically and pragmatically efficient for a significant portion of those who use them, (3) the **signs** are environmentally and socially general in the **seman-**

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

tic and pragmatic sense and, (4) the instructions signify ways of permuting and combining **signs** in the **set** to form **sign** complexes that also satisfy conditions (2) and (3)".

Thus, any language implies a previous consensual **process** and **transmission** by a teaching-learning **process**. Unfortunately, non-formalized languages – even common languages controlled by academies and other similar institutions – may easily be distorted by ideologic manipulations or prejudices.

Systemists should thus take a clear conscience of the frequent lack of **transparency** of languages.

PRIGOGINE made the interesting suggestion that language as a cooperative device between **groups** may be considered as a tool for **communication** in the same sense as, for example **chemotaxis** in amoebas and social insects.

As to D. BOHM and F.D. PEAT, they describe language as "... an **enfolded order**". Cultures and **epistemic communities** produce and reproduce the **meanings** which are "... enfolded in the **structure** of the language" and "... unfold into thought, feeling and all the activities..." (1987, p.185).

1848

LANGUAGE (Acquisition of) ^{1) – 3)}

According to N. CHOMSKY: "The person who has acquired the **knowledge** of a **language** has internalized a system of **rules** that relate sound and **meaning** in a particular way... Evidently, **knowledge** of language – the internalized system of **rules** – is only one of the many factors that determinate how an utterance will be used or understood in a particular **situation**" (1969, p.23).

About the **process** of internalization, H. ATLAN states, more precisely: "...acquisition of language (can be) seen as a **self-organizing system**. The older stages or first steps in the **process** appear as **states** of indifferentiation, with high **redundancy** in the sense that many different **signs** and **symbols** are equivalent because they have vague, overlapping **meanings**. It is only at later stages that the language has become more diversified, more differentiated, as a result of a reduction in **redundancy** such that every **sign** becomes different in a different specific way.

"Therefore a **semantic** unambiguous **content** is not to be found at the beginning of the **process** as some property to be added to, or part of, built in syntactic **structures**, but rather at the end of the **process**; starting from a non specific, **polysemic** and to same extend pre-syntactic **structure**, ending as a strictly defined **syntax**, while completely non **ambiguous meaning** as in artificial logico-mathematical language".

"From this point of view the evolution of the **semantic** component of language is not seen as an acquisition of **polysemic** and **metaphorical meaning**, starting from well defined literal, nonambiguous **meaning**, but just the opposite." (1972, p.245).

However, an important degree of **polysemy** subsists in any non formal language at the individual **level**, and most necessarily at the social **level**. Any creative elaboration of new information depends on it.

From another viewpoint, it should be observed that: "... the acquisition of language is not the result of an organized **instruction**, but takes place just by immersion in the **environment**" (A. CLEREMANS, 2000, p.84). Of course, the author means "the social **environment**". This explains the frequently poor results obtained by any teaching **method** which does not includes such immersion... as well as the basic acquisition of the mother language without any schooling at all, as a fundamental, but also automatic part of the general **socialization process**. It is a kind of systemic **conditioning**.

1849

LANGUAGE and CULTURE ^{1) – 3) – 4)}

Language is a cultural **whole**, i.e. is the indispensable carrier of **values** and **norms** in any human **group**.

Moreover, language is a system in its own right. The study of the **structures** of languages, starting with F.de SAUSSURE may even be considered as one of the oldest roots of **systemics**.

The linguistic system is different in different human **groups** and contributes to maintain and even to deepen cultural differentiation, as it is transmitted, transformed and reconstructed through generations of users.

In KORZYBSKI's terms, **time binding** is accomplished mainly by language use.

On the other hand, as emphasized by B. L. WHORF, every language bears significances proper to the **community** that evolved it. In his words, there is a: "... give and take between language and culture" (1972, p.143) whose effects he retraces in very different languages. This explains why, as said in Italian: "Traduttore, traditore".

In a still more general way, D. BOHM and F.D. PEAT: "...argue that the whole area of **perception** and **communication** must be considered as an indivisible **whole**" (1987, p.142).

Similar comments about the problems of translation which result from crossing cultural barriers have been made by A.L. BECKER in his study of Burmese language and even script (1995)

Generally, only a good **knowledge** of other languages (specially for Westerners, of non-western ones) may lead to "defamiliarization" and the **recognition** of one's own biases.

And only this kind of jumping cross-cultural frontiers could help to end intercultural misunderstanding and distrust.

→ **Semantics; Semiotics; Weltanschauung**

1850

LANGUAGE COMPETENCE ^{1) – 4)}

"The ability of an individual to transfer the **concept-components** of his own **memory** (by copying it with varying fidelity) into the **memory space** of another individual through language" (V CSANYI, 1993, p.266).

CSANYI comments: "This copying **process** is **replication**, that is the propagation of the **concept-components** in a physical sense" (Ibid).

A material or energetic carrier is necessary, as well as a modulating **code**. Moreover capacity of correct **transmission** and reception must be shared by senders and receivers, i.e., for instance, their being able to read and have a common **knowledge** of English.

CSANYI signals an overall important consequence: "... the **evolution** of concepts is not restricted anymore by the longevity of the individual. Individuals living in a linguistic **community** join their **memory space** and create a common replicative **space** with many orders of magnitude larger than the individual ones. With this new mode of **concept replication** a new evolutionary **process**, culture commences" (Ibid).

These views are akin to KORZYBSKI's "**time binding**".

1851

LANGUAGE (Digital or Analogic) ⁵⁾

Communication languages can be digital or analogic.

According to A. WILDEN: "**Digital communication**, which depends on the combination of discrete and **discontinuous elements** that can be generally considered as arbitrary **signs**, has more logical **complexity** -but less **semantic wealth-** than **analogic communication**" (1972, p.48).

Indeed, **digital** language corresponds to the pure logical formalism of BOOLE's **binary algebra** (1952) and concerns itself basically with **communication** techniques, but not with **semantics**.

Compare with the concepts of "**metron**" and "**logon**" of D. GABOR and D.M. MacKAY, with K. STEINBUCH's **learning matrixes** and A. KORZYBSKI's **structural differential**.

1852

LANGUAGE (Formal) ²⁾

A language connecting a **set X** of basic **elements** or **symbols** and a set **G** of **rules** that organize them.

Formal languages eliminate imprecise statements and permit a rigorous **organization of knowledge**. They allow the construction of **abstract systems** applicable to the establishment of coherent **models of concrete systems**.

However, the selection of the **elements** or **symbols** and of the **rules** are still the responsibility of the **modeler**.

1853

LANGUAGE (Internal and External) ^{1) - 4)}

J. PLATT states (as cited by ALLEN and STARR - 1982, p.86): "In general the internal language of a system is never the same as its external language to the **environment** or to other systems".

ALLEN and STARR give some biological examples of this, but such differences between internal and external languages are possibly still more obvious in the cases of institutional systems (e.g. the judicial system), economic ones (enterprises) or political and cultural ones (e.g. the Catholic Church, Japanese society).

1854

LANGUAGE (Visual) ¹⁾⁴⁾

A language made of **images** whose **meaning** does not depend of any specific linguistic or cultural **context**.

Such a language of universal acceptance and **understanding** is mainly a result of the swift **growth** of a worldwide **communication network** based on **technology**.

It includes **ideograms** indicating for example telephones, restaurants, rest rooms, baggage rooms or booths, **information** stands, medical help, etc... in airports and railways stations. Roads signs indicating crossroads, curves, railways crossings, entries and exits, one-way traffic, parking lots, etc... are other ideograms. In many cases, arrows or flashing **signs** are used.

Other conventional **signs** representing for example some currencies (dollars, yens, pounds, euros), many times completed by small flags, are now widely used and recognized.

Still other **signs** are widely used in electrical artifacts and **networks** and in **storage** and transportation of dangerous products.

Moreover, a growing number of private concerns are slowly imposing their own brand images or logotypes: Special foods, or credit cards, for instance.

Another **domain** wherein this visual language is growing apace is the **representation** of systems or their **parts** by, for example, **graphs**, figures, drawings, or **flow charts**.

The appearance of such a universal language is doubtless part of the construction of a world system at a higher **complexity level**.

1855

LANGUAGES (Hierarchy of) ^{1) - 3)}

In relation to WITTGENSTEIN's, TARSKI's and GÖDEL's logical investigations, and in B. RUSSELL's words: "... every language has, as Mr. WITTGENSTEIN says, a **structure** concerning which, *in the language*, nothing can be said, but that there may be another language dealing with the **structure** of the first language, and having itself a new **structure**, and that to this hierarchy of languages, there may be no limit" (quoted by L. LÖFGREN, 1979, p.247).

This is obviously also related to B. RUSSELL and A. N. WHITEHEAD's **theory of types** and GÖDEL's **Incompleteness theorem**.

1856

LANGUAGES: Special and common ^{1) - 3) - 4)}

J. ENGELBERG makes the following comment: "Every area of specialization possesses a special language. Its existence magnifies the **efficiency** and power of thought and **communication** within that area; however it also isolates practitioners of various fields from one another, and from non-specialists as well.

"By contrast, the language of integrative study is the common language... This language seems to have been devised precisely to meet the needs of the realm of **wholes**, the realm in which every person ultimately has to live. It is reasonable to assume that natural language evolved to facilitate **integration**" (1991, p.11).

Unfortunately, even the cybernetic-systemic language tends to specialize, and we should try to limit this tendency as much as possible by using an absolute minimum of specific vocabulary (and still less, jargon) and create it in the most simple terms, in order to remain comprehensible for any specialist, and also for common people.

1857

LATENCY ^{1) - 2)}

The **situation** in which some **process** remains potential during a more or less long span of **time**.

According to the nature of the system, latency can be on quite different **time scales**. The most dangerous latent **events** are those that result from a very slow **accumulation** of the **trigger** factor. This is the case, for ex. of earthquakes, volcanic eruptions, markets crashes and probably social and political sudden and violent upheavels.

Latency is a very important - sometimes quite **critical** - and in many cases overlooked condition in many **complex systems**. Latent **processes** or **events** may or may not be predictable. Their **forecast** depends on the **knowledge** of the **systems dynamics**, which

in turn depends on its strictly **deterministic** or on the contrary, **chaotic** character.

Compare with "**dormancy**".

1858

LATENCY RATIO ^{2) - 5)}

The proportion of the latent **resources** in relation to the total ones.

This **concept** was introduced by St. BEER, in "The Brain of the Firm" (1972).

This author shows the necessity of maintaining a sufficient **level** of free **resources**, that could be mobilized in case of urgency.

It is always possible to boast the productivity of a system during a limited period of **time** by using some **resource** which should normally remain reserved for **regulation** of possible internal or external **disturbances**. **Overburdening** equipment or some other critical **subsystem**, reducing or suppressing **maintenance**, depleting financial **reserves**, etc... are such questionable ways.

These dangerous **management** practice may lead to progressive shrinking of the system or, worse, to disaster in case of an unexpected crisis.

1859

LATERAL THINKING ^{2) - 3)}

A mental technique whose goal is to unfetter the mind of too narrow focuses and consequently expand the **search space** for new viewpoints.

This technique was introduced by E.DE BONO.

1860

LATTICE ²⁾

"A partially ordered **set** closed under meets and joins" (G. BIRKHOFF, 1961, p.16).

As a concrete example, the **structures** of crystals are lattices.

Lattices can be represented by closed **graphs**, oriented or not. They are basically **entanglement structures**.

As a result they can be used in the algebraic **description** of **networks**, as shown by P.H. ROOSEN-RUNGE (1966, p.14), and in the **representation** of any organized **structure**.

1861

LAW ³⁾

"A statement, together with its qualifications, that postulates a **constraint** on the conceivable **observations** and that is not contradicted by **observations** or counter examples" (K. KRIPPENDORFF, 1986, p.43)

The 19th century science tended to consider scientific laws as kinds of absolute platonician revelations about the "nature of nature".

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

KRIPPENDORFF echoes Gödelian, Popperian as well as **constructivists** viewpoints when writing: "Inasmuch as they exclude something, laws are **constructions**, not to be confused with observable **facts**". Moreover "... they are often **self-referential**" (Ibid).

It also seems difficult to think about "systemic" laws. Systemics reasons about **patterns, processes, functions, structures**, etc..., but in terms of **models, homomorphic** or, at best, **isomorphic**, to which only very few systemists, if any, seem disposed to recognize an absolute **truth value**.

1862

LAW DISCOVERY ^{2) - 3)}

H. SIMON states: "Law discovery means only find **patterns** in the **data**: whether the **pattern** will continue to hold for new **data** that are observed subsequently will be decided in the course of testing the law, not discovering it... The fact that a **process** can extract **pattern** from finite **data sets** says nothing about the predictive power of **patterns** so extracted for new **observations**. As we move from **pattern** detection to prediction, we move from the theory of discovery of **processes** to the theory of **processes** for testing laws" (1973, p.471).

G.S.theories strongly enhance our ability to discover **processes** of very general character. H. SIMON's difference between **process** discovery and laws testing parallels M. BUNGE's concepts about the need to *specify* through pertinent **data** any system that we seek to inquire by *applying* G.S.theories (see **GSTs: Epistemological evaluation**).

1863

LAW SYSTEM (Evolving) ⁴⁾⁵⁾

The Argentine barrister and systemist Ernesto GRÜN considers the different **concepts** of law corresponding to the distinct **types of human communities**, as defined during the 1996 **Fuschl Conversations**:

- In traditional communities the juridical system is based on customary or so-called common-law
- In substitutive communities dominated by some **ideology**, law is also ideologically tainted. Nazi law was based on what the party considered as "the needs of the German people"

From the communist viewpoint, law was a superstructure of economy; whether capitalist or socialist

- In learning communities, the **flexibility** and **variety** appear with the possibility of interpretation and even creative interpretation for the judges
- In evolutive learning communities, alternative ways appear for resolving **conflicts**, as for example arbitration, negotiation and **mediation**.

E. Grün can be consulted at Grun@impsat1.com.ar

1864

"LAWS": Biological and social ^{1) - 4)}

According to A. RAPOPORT, quoted by J.W. SUTHERLAND, "...we must face the fact that there are no biological or social "laws" that are direct **analogues** of the laws of motion, the law of gravity, the conservation laws of **energy** and mass, the law of increase of **entropy** in **isolated systems**, etc. At most, there are *models* of specific biological or social **phenomena**, expressible as mathematical formulae to serve as working hypotheses" (1973, p.25).

This is altogether true for so-called "systemic" laws which, if possible to enounce, would refer only to totally abstract **models** of systems.

It should be added that, generally these **models** are based in new mathematical tools as for example **input-output matrixes, graphs, fuzzy sets, "catastrophes", fractals**, etc. These **models** are basically **non-linear**, generally structural and/or dynamic, and aim at the **representation** of **interactions**, global **form** and complex **transformations**.

1865

LAWS of FORM ³⁾

→ **Form (Laws of)**

1866

LAWS or MODELS ? ³⁾

According to the preceeding comments by A. RAPOPORT, we should not confuse laws with **models**: "If it happens that several **phenomena** of widely different content can be described by the same mathematical model, both simplification and generalization have been effected. Therein lies the power of mathematical **general systems theory**" (1972, p.24).

1867

LAYER ^{1) - 2)}

The **level** of **decision complexity** in a **hierarchical system**.

→ **Level**

1868

LE CHATELIER (Principle of) ⁵⁾

"Every system in chemical **equilibrium**, under the influence of a **change** of any single one of the factors of **equilibrium**, undergoes a **transformation** in such direction that, if this **transformation** took place alone, it would produce a **change** in the opposite direction of the factor in question".

More generally, in A. BOGDANOV's terms: "... systems which are in a **state of equilibrium** tend to preserve it by producing internal opposition to forces changing it" (1980, p.54). This

way to put it opens the possibility to generalize the Principle to biological systems. BOGDANOV himself states that the principle is in reality **tektological** (i.e. systemic), or universal: "an expression of **structural stability**". He reformulates the same idea, writing: "A system of (*sic*) **equilibrium** will be called such if it maintains a given **structure** in a given **environment**" (p.112).

In physical systems, the factors of **equilibrium** are temperature, pressure, and electromotive force, corresponding to three forms of **energy** – heat, electricity and mechanical **energy**.

There is already a kind of **adaptiveness** in chemical and pre-biotic systems: a succession of such **changes** and subsequent **transformations** seems conducive to **cybernetic feedbacks** and to the **dynamic stability** that characterizes **living systems**.

One should however be careful. A. LOTKA for instance observed: "... the thermodynamic justification, at any rate in the form commonly presented (Note: in 1924, before Prigoginian **thermodynamics of systems faraway from equilibrium**), does not extend to **steady states** maintained with constant **dissipation of energy**" (1956, p.286).

A generalization of the principle in systemic terms could read: "A system tends to modify itself in order to minimize any external **perturbation**".

However some caveats should be taken into account, in the case of **complex systems**, in which the **adaptation process**:

- 1) depends upon the **activity** of internal **regulators**,... themselves frequently interconnected in quite a complex way;
- 2) is practically uninterrupted, due to the repetition... or permanence of the **interactions** with the **environment**;
- 3) revolves *simultaneously* on various **adaptations**,... mostly through interconnected **cycles** having different **periods** and **amplitudes**.

A. LOTKA quotes the following statement (by J. LOWY, as long ago as 1911!): "If the **equilibrium** of a natural complex (system of masses, **organism**, system of ideas) is disturbed, it adapt itself to the **stimulus** (Reiz) which causes the **disturbance**, in such a manner that the said **stimulus** continually diminishes until finally the original or a new **equilibrium** is again established" (Kosmos, 1911, p.331 in LOTKA, 1956, p.283).

1869

LEAD ¹⁾

The property of a **regulator** able to evaluate the future **behavior** of the system and to activate the necessary corrective **action**.

Such ability depends of the **data** available to the **regulator** (about the system itself and about its possible **interactions** with its **environment**), in accordance with the CONANT – ASHBY principle that a good **regulator** must include a reliable **model** of the system it regulates.

The lead should compensate the normal **lag** in a **feedback loop** whose corrective **action** merely *follows* the registered **difference** between the prescribed and the observed **state** of the regulated **process** in the system.

Such lagging **feedback** may be unable to correct **divergences** in due **time** and may even help throwing the **process** or system out of its **stability range**.

1870

LEARNING^{1) - 4)}

1. "The **process** of acquiring **knowledge** and skills through practice, study or **information**" (UNESCO-UNEP Glossary, 1983, p.17).
2. "The general class of **processes** by which the **behavior** of an animal comes to depend not only of the **environmental changes** immediately preceding it in **time**, but also on **events** which have occurred in the related **parts** of the **environment** in the more remote past" (J.W. PRINGLE, 1956, p.93).
3. "The retention of **adaptive response patterns** for subsequent utilization, thus abbreviating the **trial and error process** (D.T. CAMPBELL, 1975, p.17).
4. "The **reduction** in the **randomness** of behavioral **elements**" (R.W. FULLER & P. PUTNAM, 1967, p.104).

These very different definitions (and many others have been given) show the complex nature of learning.

Learning is a very general ability of **living systems**. Basically it "... consists in the formation of new **neural patterns**, i.e. in establishing permanent **connections** among neurons or facilitating ephemeral (but repeatable) **interconnections** among them. Some **connections** may be formed accidentally (at **random**); if valuable, they have a **chance** of becoming established or recurrent" (M. BUNGE, 1979, p.133).

This has been demonstrated in lower **organisms** such as cockroaches or slugs. Low level learning, at least, does not even depend on the existence of the neo-cortex, nor forebrain, as mentioned by S. WALKER (1983).

PRINGLE makes an important comment to his definition: "The modification of present **behavior** by past **events** is called learning when those **events** have occurred during the lifetime of the individual, and instinct. when the **events** have occurred outside this period of **time**. In the former case the past **events** are supposed to have left some trace in the animal (usually in its nervous system), whereas in the latter case the **organization** of the animal responsible for the observed response is supposed to be in-

nate: that is to be contained fully in the material substance of its inheritance. This **distinction** is clear-cut theoretically, although great difficulty has often been experienced in assigning to one or other case the particular aspect of **behavior** which is the subject for study" (Ibid., p.74).

W.R. ASHBY stresses that "learning usually changes **behavior** from a less to a more beneficial, i.e. survival promoting, form" (1960, p.3-4).

He adds that "The nervous system is well provided with means for **action**. Glucose, oxygen and other metabolites are brought to it by the blood so that free **energy** is available abundantly... The nervous system, then, possesses almost unlimited potentialities for **action**".

But this does not explain why learning is *beneficial*: "We are concerned primarily with the question why, during learning, **behavior** changes for the better; and this question is not answered by the (*mere*) fact that a given **behavior** can change to one of lesser or greater **activity**. If a dynamic system is allowed to proceed to vigorous **action** without special precautions, the **activity** will usually lead to the destruction of the system itself" (p.4-5).

ASHBY's book "Design for a brain" is mainly trying to explain this basic question by developing a **model** of cybernetic acquisition of cerebral **organization**, with the appropriate **constraints** and **heterogeneity**.

As to FULLER and PUTNAM, they understand the learning **process** in a negative way "... rather than as the incorporation of **order** in a blank photographic plate" (p.104) and, through a **random search process** as "... the discovery of more and more **relative dominances** through interacting with (the) **environment**" (p.105).

R.L. ACKOFF stresses another important point: "Since learning can take place only when a system has a **choice** among alternative courses of **action**, only systems that are **goal-seeking** or higher can learn. If a system is repeatedly subjected to the same **environmental** or internal **change** and increases its ability to maintain its **efficiency** under this type of **change**, then it learns how to adapt. Thus **adaptation** itself can be learned" (1972).

1871

LEARNING (Action)

→ Action learning

1872

LEARNING ALGORITHM^{2) - 3)}

A **set of rules** that does not rigidly determines the **behavior** of a system, but defines the basic characteristics and limits of all its potential **behaviors**.

The learning algorithm is implicit in any **neural network** which possesses a predetermined **structure**. Such a **network** organizes itself and constructs behavioral **patterns** by **interaction** with its **environment**. These **patterns** are conserved, or evolve within the limits of the **organizational closure** proper to the **network**.

The learning algorithm is a kind of second degree **algorithm**, that is able to produce numerous simpler and more specialized **algorithms**.

It allows an "economy" which, in G. BATESON's words "... consists precisely in *not* re-examining or rediscovering the premises of **habit** every time the **habit** is used" (1967, p.245).

1873

LEARNING as a description process¹⁾

According to L. LÖFGREN: "We think of the basic **function** of our **brains** as a learning or **description process**, which produces short and communicable **descriptions** of the enormous, and in itself unmanageably complex, **data-flow** that is our direct experience of an outer world (surrounding)" (1977, p.199).

Such **brain-internalized descriptions** tend to become evermore **stable** and can thus be used as a simplification device for the synthetic interpretation of considerable chunks of outer world **data**.

In LÖFGREN's words: "Involved is the idea that the more regularities have been found, the more can be utilized (be referred to) in the **description** to make it shorter (than a lengthy listing of uncorrelated **facts**). Furthermore, the predictive power of the **description** will increase with the number of regularities found... Then more reliable **predictions** can be made on the basis of the learned **description**, and more safe **inferences** can be made of how to behave in the surrounding" (Ibid).

These views confirm that learning is a **brain process** of **algorithms** creation.

1874

LEARNING as cerebral differentiation¹⁾

In his paper: "Unidad biológica de cerebro y mente", J.M. RODRIGUEZ DELGADO (1993, p.265-6) shows that the **brain** do structure and organize itself by way of the learning **process**. The following facts can be mustered in support of such an opinion:

1. We do not remember our first infancy precisely because our **brain** had not yet created many of the **structures** needed to register most **events**.
2. Our mental faculties can express themselves only through what we have learned. DELGADO points out for example, that "Most of western people are illiterate respect to Chinese, Arabic

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

or other **languages**... because they did not learn the corresponding **reference frame**" (p.261).

3. The so-called wolf children, even when back to civilization, are very difficult to educate "because their **brain** did not receive the needed sensorial stimulations and grew up without **language**, a fact which produces grave anatomical, neuro-chemical and functional deficiencies" (p.266).

This basic fact has been thus stated by H.von FOERSTER: "I believe that the ultimate reason... systems should learn at all is that learning enables them to make inductive references. In other words, in order to enhance the chance of **survival**, the system should be able to compute future **events** from past experience".

As stated by V. ROWLAND: "...the **organization** of learning involves the development of timing within ensembles of neurons that enable the **organism**... to have the timing of all elemental **processes** brought into **coherence** with the **activity** of a total ensemble" (1976, p.124).

This **understanding** is consonant with the **autopoietic** concept of **organizational closure**. In J.L. LOCKE words: "Long before they utter a word, infants are talking *themselves* into a **language**" (1994, p.436). It seems to be a kind of **endogenous** organizational **process**, based on preexistent physiological **structures**, and on selective **interpenetration** reactions to the **perception** of external **events**.

1875

LEARNING AS SELF-REORGANIZATION ²⁾³⁾⁵⁾

R. NUMMELA CAINE and M. CAINE, centering their attention on **knowledge acquisition**, contend that: "Acquiring new natural **knowledge** fundamentally changes the way in which we perceive ourselves. In meaningful learning, the **brain** itself is reorganized, and that has consequences for the perceived self"

And: "We suggest that this **process** (of active **uncertainty**) is critical to helping the **brain** make maximum **connections**" (1994, p.137-8)

In relation to the inner **perception** of the sudden **emergence** of a new and re-arranged **understanding** (the so-called "aha" episodes), they add: "The **emergence** of the "aha" is frequently preceded by periods of **uncertainty** or **ambiguity** and hard, intrinsically motivated work requiring **delay** of other forms of gratification" (Ibid)

This is not only the case in learning but, possibly still more so in artistic and scientific **creativity**: great new **concepts** mostly seem to appear in flashes of sudden insight... duly prepared by a long period of frustrating and obscure useless **trials and errors**. Many great scientists have given their testimony on this.

→ also: **Self-reorganization**

1876

LEARNING (Back-propagation) ^{1) - 5)}

Learning seems to be basically a recurrent two stages **process** in **neural networks**, a **model** of which could be the **back-propagation algorithm** in neural computer **networks**.

According to G. HINTON "The most serious objection to **back-propagation** as a **model** of real learning is that it requires a teacher to supply the desired **output** for each training example. In contrast, people learn most things without the help of a teacher. Nobody presents us with a detailed **description** of the internal **representation** of the world that we must learn to extract from our sensory **input**." (1992, p.108).

It could be argued that **living systems** have such a "teacher", in the guise of their genetic **structure**, which allows them to start from basic physiological standards, genetically **embedded**, that can be "educated". The natural respiratory **rhythm** or the sense of **equilibrium** seem to be good examples. Learning however, to ride a bicycle is basically a self-correcting **back-propagating process**.

The general sequential learning **process** should thus be:

- put to use or establish a basic standard
- calculate the **output deviation**
- correct the **inputs** in order to obtain a better correspondance with the standards

At a more complex **level**, a **process** of correcting the standards themselves may appear, specially behavioral, conceptual or ethical ones, through ethological or cultural **interaction**.

1877

LEARNING by DOING ¹⁾

"The **process** of acquiring **understanding**, **knowledge**, skills and attitudes through practical and applied learning activities" (UNESCO-UNEP Glossary, 1983, p.17).

The following comments are added: "A relatively permanent **change** in the **behavior** (and attitudes) (is observed) as a result of the individual's experience in doing. (It involves **observations**, investigation, **inquiry**, **problem-solving**, and **value** clarification, which are effective learning methods in **environmental education** and field **situations**" (Ibid).

Learning by doing is thus a very important systemic **activity**.

1878

LEARNING by normative feedback ¹⁾

In a **net** of biological neurons, the global capacity of the **net** results from the **self-organization** of neural **connections** under the effects of the **inputs** that they receive and transmit.

L. PERSONNAZ et al. state: "The principle of this **self-organization** is simple: The **efficiency** of any synapse is reinforced when the neurons that it connects have a tendency to be active or inactive simultaneously; in the opposite case it lessens" (1988, p.1364).

This effect is strengthened locally within the strongly connected **net**, by repeated **feed-backs**.

Learning seems to be the progressive dynamic **stabilization** of **frames of reference** within the more or less narrow **limits** of a **repertoire** of stored **information**, relevant within a kind of pre-imprinted but very general **program**, while the irrelevant **data** are not retained.

See for example N. S. CLAYTON about song learning in birds (1991, p.466-72).

It could be a progressive algorithmization of **behaviors**. The upbuilding of such **algorithms** could possibly be modeled through **attractors**.

These concepts are also relevant for the new forms of **perceptrons** (recognition of more or less well written or printed types, for example).

1879

LEARNING COMMUNITY

→ **Communities (Types of Human)**

1880

LEARNING COMMUNITY (Evolutionary)

→ **Communities (Types of Human)**

1881

LEARNING (Competitive) ²⁾⁵⁾

In **parallel processing networks**, "an unsupervised learning **procedure** in which the **network** is presented with a series of **input patterns** and must discover regularities in those **patterns** that can be used to divide them into **clusters** of similar **patterns**" (Adapted from W. BECHTEL & A. ABRAHAMSEN, 1991, p.304)

The authors add that **input patterns** are selected through "inhibitory **connections** among the **detector** units to assure that just one unit will "win" the **competition** for a particular **input pattern**" (p.305).

In this way, **inputs** become classified in **categories**.

"In more complex systems there may be multiple **nets** of **detector** units, or intermediate **layers** of units" (p. 305)

Interesting **heuristic analogies** can be drawn with the ways human **brains** are learning.

1882

LEARNING (Double-Loop) ^{1) - 3)}

A learning **process** that enables the system to learn to learn.

This model has been introduced and developed mainly by W.R. ASHBY (1956) and G. BATESON (1973), who also called it "Deutero-learning" (see "Learning levels").

It implies the **emergence** of generalization **rules** of **induction**. **Systemics** is a typical double-loop learning tool.

1883

LEARNING (Evolutionary reinforcement)¹⁾

A form of individual learning that should have an influence on the **evolution** of a **group** or a species.

This hypothesis was proposed by D.H. ACKLEY (quoted by S. LEVY, 1992, p.265), who writes: "As dictated by their genetic **code**, **agents** would actually develop *two neural networks*: an "action network" that would convert sensory **input** into **behaviors**, and an "evaluation network" that would also draw from sensory **input**, by using that **information** to judge whether a particular **situation** was good or bad. Depending on the **feedback** it received after acting on that judgment, the **agent** would reinforce, or modify, its **behavior**" (1992, p.265).

It seems for example that individual **ethological adaptation** (e.g. the monkeys who learned to clean potatoes in sea salt water, in Japan), transmitted from generation to generation, modify the **ecological niche** of the species as a whole and could eventually lead to a different **selection** of **random** mutations.

ACKLEY successfully applied the idea to define a **set** of **rules** for evolving **groups** of **artificial organisms**, with positive results.

The **model** – a kind of Lamarckian transmission of acquired **behavioral patterns** – could probably be useful for the **understanding** of the way human **organizations** react to individual **adaptations** and innovations of some of their members.

1884

LEARNING (Fourth Order)²⁾

"Changes in those **processes** of change referred to in **3d order learning**" (Adapted from 1973, p.220).

According to BATESON: "Whether learning of this fourth order occurs in human beings is unknown" (Ibid).

4th order learning could probably be related to critique of **metaconcepts** formation, of the kind developed by GÖDEL, CHURCH and TURING. (see Ch. FRANÇOIS, 1987). Systemic and cybernetic **isomorphisms** could be considered as a basement for this 4th. order learning.

It should however be necessary to find a corresponding **neural networks mechanism**.

1885

LEARNING HEURISTICS (Basic)³⁾

M. MINSKY and O. SELFRIDGE (1960) proposed the following method: "In a novel **situation** try methods (**parameter** adjustment, **network organizations**) like those which have worked best in similar **situations**" (quoted by G. PASK, 1961, p.83).

This may be a quite useful **method**, but it is not very innovative.

M. MINSKY, in particular, around 1960, as a critic of F. ROSENBLATT's **perceptron**, was not optimistic about the practical possibility of evolutionary self-learning or self-organizing **networks**, which are based on loose behavioral **rules**, and not on precise and limited **algorithms**.

More recently, ways out of these difficulties have been introduced. See "Artificial Life" and "Intelligence (Distributed Artificial)".

1886

LEARNING LEVELS³⁾

G. BATESON describes a **hierarchy** of learning levels, as follows:

1. 1st order learning: The simple receipt of a **signal** within a formerly ordered **pattern**, with the corresponding triggering of an **action**.
2. 2d order learning, practically equivalent to **pattern** modification through experience or experiment.
3. 3d order learning, which implies a capacity to reform learning **processes** through reappreciation of **pattern** modification and their results, with subsequent modifications the mode of **pattern** construction.
4. 4th order learning, which is still more or less hypothetical and would imply a general **methodology** for **pattern** reconstruction and invention.

See details under specific headings.

1887

LEARNING MACHINE²⁾

"A machine capable of performing certain **actions** even though the builders do not know **algorithms** for these **actions**" (P. DENNING, 1992a, p.14).

The learning machine constructs its own **algorithm** to perform the task.

DENNING explains that it does so by adjusting "internal **parameters** of an **associative memory**", as it registers successive examples "each consisting of an **input** and a corresponding ideal" (Ibid.).

He adds: "...the machine's internal **structure** can be represented by a **set** of **rules** telling it how to respond to given **inputs**".

Moreover: "After each **action**, the machine uses the resulting pay-off **feedback** to modify its **rule set** so that an effective **behavior** is reinforced or an ineffective **behavior** is dropped".

In this way "... a **population** of **rules** evolves over **time** and the **rules** producing the highest pay-offs come to dominate the **population**". Thus "**Genetic algorithms** are being used as the builders of **programs** inside learning machines" (Ibid).

In order to be able to perform a task, a learning machine needs thus an **algorithm** producing **algorithms**, i.e. a genetic **algorithm**. Such a **meta-algorithm** must by necessity be able to produce, experiment and select combinations of basic **rules**.

The concept apply also quite probably to natural learning machines.

1888

LEARNING MATRIXES (STEINBUCH's)²⁾

A **model** of learning **processes** through a **commutative structure** represented by a matrix.

Such **models** have been proposed by the German cybernetist K. STEINBUCH. (See K. STEINBUCH, 1961; N. WIENER & J.P. SCHADE, 1963 and G. KLAUS und H. LIEBSCHER, 1976)

As in any matrix, the **structure** consists in a table connecting horizontal and vertical **elements**, in such a way as to represent stipulated **interconnections**.

The so-called "lern-matrix", which represent the process of learning proper ("Lernphase"), connects at any intersection in the matrix some property, i.e. basically a perceived characteristic, with a **meaning**, i.e. a corresponding **symbol**, verbal or otherwise. Once the matrix has been constructed, the so-called "Kannphase" (i.e. **knowledge** phase) is reached, in which it is possible to retrieve any characteristic through the corresponding **symbol**.

In general, **connection** of **meanings** with properties is the basic condition of the shaping of **semantic codes**. It is thus also the basis for the creation of **information**, as it is the **connection** that transforms **noise** into **meaning**. It implies however the **pre-existence** of a physiological **substratum** (for ex. visual **perception** or phonation capacity) through which **rules** for **connections** can be expressed. Moreover, any individual has his/her own **autopoietic closure**. As a result, **rules** may vary slightly for different individuals.

It is possible to construct learning matrixes at various interconnected **hierarchical levels** of **abstraction**. This corresponds more or less to:

- G. BATESON's **levels of learning**
- A. KORZYBSKI's **structural differential**

STEINBUCH's **models** seem to represent quite accurately the formation and subsequent uses of **representations** obtained from **perceptions**.

→ "Learning processes"

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

1889

LEARNING (Observational)¹⁾

D.T. CAMPBELL describes observational learning "as characteristic of *social* animals, in which the observing animal learns from observing the outcomes to an exploring animal, and thus even profit from experience that may prove fatal to the exploring animal" (1961, p.18).

This type of **behavior** has been observed, for instance, in rats.

Social animals may also learn from the **observation** of the traces of **activity** left by other or former members of the **group** (**stigmergy**).

1890

LEARNING PROCESSES³⁾

E. JANTSCH proposed the following characterization of different learning processes, as related to **consciousness**:

"- **Virtual learning** is characteristic of non-reflective **consciousness** (sic) (JANTSCH gives examples from quantum physics and **dissipative thermodynamics**).

"- **Functional learning**, characteristic of reflexive **consciousness** or simple **perception**, may be graphically depicted by the **feedback interaction** between **consciousness** and **environment** which appear here in a **binary** link. This kind of **interaction** is found in biological and primitive social **processes**.

"- **Conscious learning**, Characteristic of self-reflective **consciousness**, may be viewed as the multiple **feedback interactions** in the ternary system formed by **consciousness**, the **environment**, and a **memory** or **storage** system which may be termed the "appreciated world" and which of course is itself part of **consciousness**...

"- **Superconscious learning** characteristic of a more complex kind of self-reflective **consciousness** which mirror itself in a "surface" **consciousness** as well as in a multilevel superconsciousness of "depth" **consciousness**..." (1976, p.41-42).

The problem with this classification is that the concept of **consciousness** is at the same time abstract and subjective. On the one side, it seems difficult to accept so-called "nonreflective **consciousness**" in physical systems (Is this not an anthropomorphic **metaphor**?). On the other hand, **consciousness** is something which happens in the nervous system (and more precisely in the cortex) and we still lack a clear **understanding** of how it is produced.

Another view on learning processes is S. GROSSBERG's (as commented by R. FISCHER, (1992, p.235):

"In GROSSBERG's adaptive **resonance** theory (1987) learning and **memory** are basically identical **processes**. Raw sense **data** from "out there" combine with the **associations** from the past and resonate until a coherent **image** is formed.... What resonates in GROSSBERG's **model** is a cloud of neurons – an **interconnected group of cells** surrounded by inter-neurons – that together form an electronic **feedback** system which resonates in **response** to a particular **class** of sensations... The functional unit of short term **memory** is a **resonating pattern** (of **synaptic weights**) that fades in about 15 seconds if not committed to long term **memory** through **association** with "remembrance of things past". The conscious experience of daily routine then, is a **pattern-matching game** between the novelties perceived and the known **patterns**".

→ **Learning matrixes**

1891

LEARNING (Reinforcement in)²⁾

The strengthening of a behavioral or mental **pattern** by the occurrence or experimental introduction of a relevant **stimulus**.

G. BATESON remarks: "The notion is that **random changes** occur, in the **brain** or elsewhere, and that the results of such **random change** are selected for **survival** by **processes** of **reinforcement** and extinction. In basic theory, creative thought has come to resemble the evolutionary **process** in its fundamentally stochastic nature".

However: "In both the theory of **evolution** and the theory of learning, ...the word '**random**' is conspicuously undefined and the word is not an easy one to define ... Underlying both the stochastic theory of **evolution** and that of learning, there are *unstated* theories regarding the determinants of the probabilities in question. If however, we ask about **change** in these determinants, we shall again be given stochastic answers, so that the word '**random**', upon which all of these explanations turn, appears to be a word whose **meaning** is hierarchically structured" (1973, p.226).

Once again, we find ourselves confronted to the basic problem of the **meaning** or our concepts. In our definition "strengthening" and "relevant" imply the existence of some former **structure**, already more or less **autopoietic**: How was it instated?

1892

LEARNING RULE (HEBB's)^{2) - 4)}

In 1949, the Canadian neurologist D. HEBB formulated the following learning rule: "When an axon of cell A... excite(s) cell B and repeatedly or persistently takes part in firing it, some **growth process** or **metabolic change** takes

place in one or both **cells** such as A's efficacy, as one of the **cells** firing B is increased" (1941).

E.R. KANDEL and R.D. HAWKINS, who quote this author, write: "According to HEBB's learning rule, coincident **activity** in the presynaptic and postsynaptic neurons is critical for strengthening the **connection** between them (a so-called pre-post associative **mechanism**)".

HEBB's rule could possibly be generalized to interpersonal and intergroupal **communication** in social systems, which are obviously **networks** in their own right.

1893

LEARNING (Second Order)^{1) - 2)}

Any **process** (in a **hierarchy** of such **processes**) which modifies an already ordered and registered significant **pattern**.

In G. BATESON's understanding, 2d order learning implies a reordering of the former **pattern**, in relation to the **emergence** of a new **signal**, or some alteration brought to the existing one. He gives the following examples of 2d order learning experiences or experiments: "Pavlovian, instrumental reward, instrumental avoidance, rote and so on" (1973, p.220).

1894

LEARNING (Systemic)^{1) - 3) - 4)}

A set of ways and means to acquire an integrated **understanding** of ourselves, our society, our **environment**, and all the significant **interrelations** which connect them.

What we need – all of us – is a **meta-knowledge**, a way to look at this complex world in all its stances and to understand what is going on and what may, possibly, happen.

Let us however not be blinded by high-sounding "**meta-knowledge**". Many of our forefathers did possess at least something of it, passed along by their cultural heritage as "popular wisdom" (fables, proverbs, myths, scriptures, etc.). These tales and sayings proposed, in a covert way, quite general interpretations for many **events**. This is precisely what our actual instructional and educational **process** does not offer anymore. Our excessively specialized and micronized **knowledge** bars us the **understanding** of global **situations**, which is precisely what we must recuperate.

We all became all-out mechanists-voluntarists easily devoid of common sense. The dominant scientific **paradigm** led us to conceive and understand everyone of our projects (material, personal or social) as a rather simple "**machine**" that we construct on the base of some **linear cause-effect** principle in order to reach some clear-cut and defined result. Most of us never doubt that such aims will be necessarily attained, just in the way we did plan our project. Nevertheless, we now have thousands of examples of precisely the opposite.

This is because we ignore, at least in our practice, **nonlinear** multiple **connections**, and have a very deficient **perception** of **time** dimensions (which leads us to unwarranted **extrapolations**).

Systemic learning should aim at the creation of a good **understanding** of every kind of **complex systems**.

Generally speaking, this suppose the intuitive and later on, the rational appreciation of their constitution, inner workings, their **transformations** and **interrelations** among themselves and with their respective **environments**.

General systemics and cybernetics offer an ever widening set of **isomorphies**, **models** and **methods** to obtain such results.

1895

LEARNING (Third Order)^{2) - 3)}

"Those learnings which constitute changes in **2d order learning**" (1973, p.220).

At this level, we already have learning to learn **processes**. Actually BATESON first proposed to call these **phenomena** "deutero-learning" and later on "trito-learning", expressions which never became firmly rooted into usage.

In a **hierarchy** of learning **processes**, 3d order learning implies the capacity to **understand** and to modify conditioning through a better appreciation of **context** and thus, up to a point, to reconstruct behavioral or mental **patterns**.

1896

LEARNING (Trial and error)¹⁾

This expression was coined by L. MORGAN in England and E.L. THORNDIKE in the United States.

W.R. ASHBY observes: "The **process** of trial and error can then be viewed from two very different points of view. On the one hand it can be regarded as simply an attempt at success; so that when it fails, we give zero mark for success. From this point of view it is merely a second rate way of getting to success. There is, however, the other point of view that gives it an altogether higher status, for the **process** may be playing the invaluable part of *gathering information*, **information** that is absolutely necessary if **adaptation** is to be successfully achieved" (1960, p.83).

The result of every trial is:

1. recorded in the **memory** of the system
2. integrated in a non-contradictory **structure** of internally organized **information** i.e. **knowledge**
3. also possibly integrated into a **repertory** of automatic **responses** or skills.

Each trial modifies the internal **state** of the system and predisposes it to a better adapted future **activity**, even if some cases some trials (followed by good or negative results) must be repeated several times.

ASHBY's own **Law of Requisite Variety** is obviously an elaboration on the usefulness for a system to enrich its **repertories** of possible **states** or **responses** to variations in its **environment**.

Learning by trial and error, as an internal ordering **process**, is also related to the **model of order from noise**.

1897

LEARNING (Types of)¹⁾

J.W.S. PRINGLE distinguished (1951) the following different ways of learning:

1. **Habituation**, which results of a repeated **reaction** to repeated **stimuli** of one specific kind. This effect may disappear if the interval between repetitions is too long.
2. **The conditioned reflex**, which associates by convenient training a **response**, at first elicited by a specific **stimulus**, to another **stimulus**.
3. **By trial and error**, in which a **response** is selected by the **subject** after a number of more or less **random actions**.
4. **Insight learning**, by which, in a new **situation**, a **response** is selected from a number of possible **responses** resulting from previous more or less similar experiences.
5. **"Imprinting"** (in birds and insects), by which the environmental **situation** at certain critical periods in the animal's lifetime becomes specially effective in producing permanent modifications of subsequent **behavior** (p.94).

PRINGLE's paper is about these various learning ways.

E. LASZLO has stretched the concept of learning in relation to the different **levels** of natural systems. His views have been resumed by E. JANTSCH as follows:

"Virtual learning is characteristic of non-reflective **consciousness**...

"Functional. learning, characteristic of reflective **consciousness**, or simple **perception**... This kind of **interaction** is found in biological and primitive social **processes**...

"Conscious learning characteristic of self-reflective **consciousness** or apperception ... the normal **mode** of learning and of becoming creative in the human social realm ...

"Superconscious learning, characteristic of a more complex kind of self-reflective **consciousness** which mirrors itself in a "surface" **consciousness** as well as in a **multilevel** superconsciousness or "depth" **consciousness** ... (It) provides a sense of direction for cultural and mankind progress by "illuminating" the **process** from the far end in terms of guiding **images**".

"These learning **modes** characterize **levels** of macroscopic coordination of interactive **processes**" (1976, p.41-42).

One only wonders if **consciousness** can exist without being reflective.

D. DUBOIS offers still another **classification** of types of learning:

"1. **Learning** as the **process** of creation of new **representations**... Ready-made **representations** can be proposed to intelligent systems who can assimilate them.

"2. **Self-learning**, the **process** through which (such systems) create themselves new **representations**.

"3. **Meta-learning** related to the learning of learning. It can be taught through **rules** that guide or channel the learning process.

"3. **Meta-self-learning** related to the intelligent system's reflexion on his/her self-learning **methods**. This is related to the **phenomenon** of **consciousness**" (1990, p.180)".

1898

LEARNING (Zero)^{2) - 3)}

"The simple receipt of **information** from an external **event**, in such a way that a similar **event** at a later (and appropriate) **time** will convey the **same information**" (G. BATESON, 1973, p.255).

This definition needs at least one qualification: Zero-learning is not independent of **context**, which, in BATESON's definition is present through the words "similar" and "appropriate". BATESON's own example indicates as much: "I learn" from the factory whistle that it is twelve o'clock". This implies:

- 1) that I have registered former experience that the factory blows the whistle every day when my watch indicates 12 o'clock;
- 2) that the factory's whistle is not blown randomly for example again 10 minutes later, which, if I have no watch, would leave me in a state of doubt as to which of the whistles really marked 12 o'clock.

1899

LEAST ACTION (Principle of)^{1) - 2)}

Motion and **change** are always achieved in a way such as the needed **action** is at the minimum.

This variation principle has its origin in celestial mechanics and mathematics. It has however been since rediscovered in quantum theory and in relativity (geodesic paths).

Least action is necessarily related to the **global fields** within which it takes place, themselves to be described in terms of **Hamiltonian systems**.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

While it probably corresponds to PRIGOGINE's **Theorem of minimum entropy production**, the status of the principle in relation to **thermodynamics of irreversible systems far-from-equilibrium, dissipative structuration and deterministic chaos** does not yet seem to be clearly established.

This principle was first enounced by Pierre MOREAU de MAUPERTUIS. J. CASTI exemplifies and comments: "This action... is an abstract quantity, like **energy** but different, that depends on the **path** of the comet between a starting point and an ending point. In principle, a comet might follow any of an infinite number of different paths - it might follow a straight line, for example, or a complicated path that wriggles back and forth. Every conceivable path has a different action, and of all these, the path actually taken has the least" (J. CASTI, 1998, p.44).

One wonders if MAUPERTUIS' principle does not signal a bridge between EINSTEIN's understanding of the relation between **time** and **space** and PRIGOGINE's understanding of the relation between **time, energy, entropy** and **emergence**.

1900

LEAST EFFORT (Principle of) (ZIPF)²⁾

"A **structure** containing a **trigger** that requires more **energy** than it releases for its own use will suffer a net reduction of potential **energy**" (As quoted by R.N. ADAMS, 1988, p.53).

J.G. MILLER gives the following interpretation to the principle: "Systems which maintain **stability** over long **periods of time** apparently tend to reduce the **costs** involved in the activation of ... associated **variables**" (1978, p.35).

He also observes that ZIPF may thus "have identified a general principle of work done by **organisms**", as his principle states "that systems use least costly **adjustments** first, and more costly ones later". This has the general meaning "that systems conserve **resources** by maintaining their **subsystem functions** efficient and by keeping down **costs**".

MILLER adds that at least in the economic sense "this is **optimization** of the **organism's behavior**" (1978, p.436). The principle also seems to be related to H. SELYE **General Adaptation Syndrome**, and his concept of **stress**.

However, according to ADAMS, the principle is somewhat of an obvious statement. Yet, its consequences can be obscured in biological **organisms** or social **organizations** in which, during a long **time**, some ill functioning **parts** are in condition to use **resources** obtained from other **parts** or **subsystems**. If such a squandering **process** is not reversed in due time the final **breakdown** becomes unavoidable.

1901

LEAST EFFORT PRINCIPLE (St. UMPLEBY)^{1) - 2)}

"An **adaptive** system will try either adapt to its **environment** or adapt that **environment** to its needs, whichever is easier" (As quoted by K. KRIPPENDORFF, 1986, p.59).

While this could be a consequence of ZIPF's Principle, it is however quite a different one.

Systematic efforts to adapt the **environment** to their needs is basically a recent characteristic of **socio-technical human systems**, with the possible older example of insect societies.

The concept may also be related to the **co-evolution** one, in which the **environment** is basically another specific system.

1902

LEVEL²⁾

"a) A section of a **hierarchy** which is defined by a **scale**".

"b) The **scale** of an **observation**" (T.F.H. ALLEN & T.B. STARR, 1982, p.271).

M. BUNGE emphasizes that ... "a level is not a thing but a **set** and therefore a concept, though not an idle one. Hence levels cannot act upon on another... All talk of interlevel **action** is elliptical or metaphorical, not literal" (1979, p.13). Formerly, BUNGE also wrote: "A level is a section of reality characterized by a **set** of interlocked properties and **laws**, some of which are peculiar to the given **domain**, and which are assumed to have emerged in **time** from other (lower or higher) levels existing previously" ("Metascientific queries", 1959, p.8).

M. MESAROVIC, D. MACKO and Y. TAKAHARA introduce three different notions of level: "1) the level of **description** or **abstraction**; 2) the level of **decision complexity**, and 3) the **organizational** level. To distinguish between these notions, we use the terms "**strata**", "**layers**" and "**echelons**" respectively. The term "level" is reserved as a generic term referring to any of these notions when there is no need to emphasize the **distinction**. We point out that, in the **description** of an actual **hierarchical system**, all three notions might be involved; the case where only one notion is applicable is an exception rather than the rule" (1970, p.37).

ALLEN and STARR state: "Many different entities may be observed scaled to a certain level distributed horizontally across a **hierarchy**" (p.271).

Complex systems are necessarily multi-leveled, as the harmony of their different **subsystems** requires the shaping of **hierarchic controls** or distributed and interconnected **regulations**, and each **subsystem** is in turn made of **elements** or **parts** and acts as their coordinator.

F.E. EMERY states that "in analysis of any one level of a system's **organization** it probably would be adequate to consider only the ones immediately above and below" (1969, p.15).

1903

LEVEL (Dominant)^{1) - 2)}

In a **hierarchized** system, the level at which some **control** operates on **elements** or **subsystems** at lesser levels.

Any **regulator** is at a dominant level in relation to that which it regulates. However, to perform correctly its **function**, it needs **information inputs** from the down level, or levels.

1904

LEVEL (in Forrester's Systems Dynamics)²⁾

The **state** or condition of the system or any of its **subsystems** at a given instant. In this context, levels are expressed quantitatively.

1905

LEVEL (Natural)²⁾

"A level identifying entities which are robust under **transformation**." (T.F.H. ALLEN & T.B. STARR, 1982, p.273).

1906

LEVEL OF RESOLUTION²⁾

"The grain **size** of an **observation** as limited by the finest **distinction** which can be made given the **observation filter**." (T.F.H. ALLEN & T.B. STARR, 1982, p.271).

ALLEN and STARR add: "In a broader sense, level of resolution includes consideration of the scope of the investigation which determines the most coarse-grained aspects of the **phenomenon** that may be recognized." (Ibid.).

1907

LEVEL (Phenomenological)^{1) - 3)}

An **observation** level directed at a **complex system**, corresponding to a clearly identifiable organizational level.

Even the global study of a system as a **whole** requires a certain degree of analytical decomposition, without which only tautological pronouncements of the type "The system is what it is or does what it does" could be produced.

The determination of any phenomenological level is unavoidably a complex compromise between the postulate of the existence of a "**concrete system**", the perceptive ability of the **observer** (with or without instrumental implements), his/her viewpoint, conceptual postulates and the practical **goals** pursued.

The phenomenological level is however by necessity the one of "direct experience, encompassing **perception** of outside things", according to J.W. SUTHERLAND, who adds, perhaps somewhat more questionably "feeling, thinking, willing, etc. (1973, p.55).

This last perceptive setting may possibly be somewhat too subjective, but is partially compensated by debate among **observers** and by the resulting **process** of **consensus**, still subject, of course, to the possibility of errors, collective biases or illusions.

1908

LEVELING MECHANISMS²⁾⁴⁾⁵⁾

This concept has been introduced by the ethologist Fr.De WAAL and is thus inspired by his observations of the way animals living in groups manage their rivalries. (2001, p. 102-107)

It seems however to be of general value.

Leveling mechanisms are indeed an absolute need in systems wherein strong tensions appear during **interactions** among **elements** or **subsystems**.

They are basically countervailing **feedbacks** acting in reaction to incipient disbalances (which can be automatically registered or psychologically perceived)

Without levelling mechanisms, uncontrolled **fluctuations** become unavoidable and, as they carry the system out of its **limits** of **dynamic stability**, can finally destroy it.

→ **Adaptability; General adaptation syndrome; Homeostasis; Interoception; Stress**

1909

LEVELS (Integrative)²⁾

A theory of Integrative Levels was summarized by J. K FEIBLEMAN as early as 1954 (1954, p.59-66), as a synthesis from previous work by K.L.von BERTALANFFY, J.H. WOODGER and A.B. NOVIKOFF.

FEIBLEMAN stated the following laws of levels:

1. Each level organizes the level or levels below it plus one **emergent** quality.
2. **Complexity** of the levels increases upward.
3. In any **organization** the higher level depends upon the lower.
4. In any **organization** the lower level is directed by the higher.
5. For any **organization** at any given level, its **mechanism** lies at the level below and its **purpose** at the level above.
6. A **disturbance** introduced into an **organization** at any one level reverberates at all the levels it covers
7. The time required for a change in **organization** shortens as we ascend the levels.
8. The higher the level, the smaller its **population** of instances.

9. It is impossible to reduce the higher level to the lower.

10. An **organization** at any level is a distortion of the level below.

11. **Events** at any given level affect **organizations** at other levels.

12. Whatever is affected as an **organization** has some **effects** as an **organization**.

To these characteristics, FEIBLEMAN added some significant **rules** of explanation related to levels of integration:

1. The reference of any **organization** must be at the lowest level which will provide sufficient **explanation**.
2. The reference of any **organization** must be to the highest level which the **explanation** requires. (FEIBLEMAN adds the following and significant comment: "The lowest levels are complex enough to make **explanation** a difficult affair, but over-**simplification** does not explain: it explains away" (p.64)
3. An **organization** belongs to its highest level.
4. Every **organization** must be explained finally on its own level.
5. No **organization** can be explained entirely in terms of a lower of higher level.

FEIBLEMAN's is a very seminal paper. Some of his **concepts** on levels have been rediscovered, and extended, later on - possibly without knowledge of his work - by other authors as for example:

- K. BOULDING with his **8 levels of complexity**
- J. MILLER, with his **taxonomy of living systems**.
- H. SABELLI who in his **process theory** emphasizes the "**priority of the simple**" and the "**supremacy of the complex**".
- H. SIMON with his "**Architecture of complexity**".
- J.van GIGCH with his theory of **metasystems**.

1910

LEVEL-SPECIFIC PRINCIPLES²⁾³⁾

Our study of nature led us to the discovery - quite recent - that no level of **complexity** can be totally understood at the lower **levels**.

In P. ANDERSON's words: " Psychology is not applied Biology, nor is Biology applied Chemistry" (1972)

To cross from one level to a more complex one we need in each case a principle that prescribes a specific way of **organization** at that level.

For example the organization of the **cell** cannot be explained merely by the **rules** of chemical valencies resumed in MENDELEIEV's periodic table of elements.

However principles at each level seem to be somehow intertwined in a more general principle of **complexification** as for example P. CORNING's **synergetic** hypothesis, or HAKEN's **power laws** or **slaving principle**, or van GIGCH's recursive **meta-control**.

In one or another way similar principles are to be found in all of the disciplines which study more or less organized **complexity**, as for example **ecology** or climatology.

1911

LIFE CYCLE

→ **Cycle (Life)**

1912

LIFE TIME¹⁾

The span of survival of a **component** in a system or **subsystem**.

According to R. ROSEN, in an arbitrary system M "... each **component** M_i of M has a finite life-time which we shall denote by u_i ; by this we mean that, after M_i has been in **operation** for an interval of **time** u_i it shall cease to function." (1974b, p.31).

This is a very general property of **components** in **complex systems** (**living systems** and **organizations**, and in an analogous way, **machines**). The replacement of **components** by other **components** of the same type is an absolute necessity for these systems and is done in **living systems** through **hypercycles** and **organizational closure**.

In order to obtain some predictive power about the life time of systems or their **components** and their probable **breakdown** time, P. WINIWARTER and C. CEMPEL have defined "life symptoms" and "life curves" in relation to **wear**. An "auto-regressive stochastic process" is observed. (1992, p.9-34).

1913

LIKEHOOD RATIO

→ **Bayes' Theorem**

1914

LIMIT^{1) - 2) - 4)}

The farthest **boundary** or **constraint** on some **process**, **subsystem** or system.

The limit is that which separates a system from its **environment**, or environmental conditions, in **space** and/or in **time**. A limitless system could not be a system at all. Limits may however be elusive in various ways: In **space**, a system has generally a **field** of influence whose **boundaries** are sometimes difficult to establish, and may be variable.

In **time**, **periodical** (or a-periodical) **variations** may expand or contract the limits of a system. The ignorance of this basic feature can be the cause of very serious problems. An example is the imprudent occupation or use of

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

the flood plains in river valleys. Another was the occupancy by uninformed British colonists of Kikuyu highland in Kenya from which Kikuyu people had to retreat after the rinder pest epidemics of the 1890's.

1915

LIMIT (Absolute) discrimination³⁾

The impossibility to differentiate sounds, colors, brightness and generally any **percept** under some minimum value.

According to K. KRIPPENDORFF, there is "...an **information** processing limit for absolute judgements by humans of about 3 **bits**" (1986, p.45).

Under this limit, confusion and errors increase rapidly. Discrimination limits are an important **constraint** in the construction of **models**.

It seems however that, through adequate **training**, discrimination limits can be somewhat extended. Examples are the use of 1/9th of tones in Indian music, or the enhanced color shades discrimination capacity of trained painters.

→ **Perception (Physiological limits to)**

1916

LIMIT CYCLE (Stable) (= Attractor)²⁾

"Closed integral curve which represents a **periodic regime**" (M. DUBOIS et al, 1987, p.193).

This **representation**, introduced by H. POINCARÉ, was indeed the first example of a (non punctual) **attractor**.

In order to obtain it, POINCARÉ introduced the notion of transverse arc: it is an arc of curve, which is tangent to none of the points of an integral curve (meaning that it intersects many times with the latter). Considering the succession of the intersections of an integral curve with a transverse arc, he reduces the study of the curve in the plane to the study of the succession of points on a line. POINCARÉ next shows that *any integral curve which does not end into a singular point is a cycle or a spiral asymptotically winding around the cycle, which he thus calls a limit cycle.*" (J.L. CHABERT & A. DAHAN DALMEDICO, 1991, p.568).

The limit cycle corresponds to the VAN DER POL equation which "describes the **behavior** of an **oscillator** which is kept going, with increase of the **oscillations** of reduced **amplitude** and decrease of those of wide **amplitude**." (P. BERGE et al, 1984, p.26).

Any **trajectory** of this kind converges towards the limit cycle, which corresponds to the type of systems tending to **oscillating dynamical stability**.

The basic condition for the existence of a limit cycle is a constant **input** of sufficient **energy** to the system. However, an excess of **energy** may throw it out of its **stability range**, in accordance with **thermodynamics of systems far-from-equilibrium**.

→ **See also: Cycle (Limit); Cycle (Stable limit)**

1917

LIMITING FACTOR¹⁾

An essential **component**, **flow** or condition whose absence, short supply or excessive concentration acts as a check on **growth** or even endangers the **survival** of a **population** or system.

According to A. LOTKA: "The significance of such limiting factors seems to have been first pointed out by J. LIEBIG: "The yield (of the soil) depends on the nutrient whose quantity is minimum".

LOTKA adds: "Limiting factors not only set certain bounds to the **growth** of the **components** to which they are thus related, but are competent also to give rise to the **phenomenon** of moving **equilibrium**" (1956, p. 97).

This is very important for **ecosystems**, which may "bounce" from one type of **equilibrium** to another under the influence of some positive or negative **variation** in a limiting factor.

G. WEINBERG proposed a "Law of limiting factors", as a generalization from the economist's Law of Diminishing Returns. (1975, p.45). However, the latter is merely a consequence of the first one, which seems more precisely causal.

In the same vein, J. WARFIELD enounced the following "Law of Limits": "To any **activity** in the universe there exists a corresponding **set** of limits upon that **activity**, which determines the feasible extend of the **activity**" (1991, pers.comm.).

WARFIELD states: "The limits may be active or inactive, generic or specific, fixed or movable, **autonomous** or responsive" (Ibid).

WARFIELD's law is very general. A frequent practical example of responsive limit is the logistic one, whose **logistic equation** is the mathematical formulation.

It would seem that any "**autonomous**" limit turns responsive when the encroaching system puts sufficient pressure on the **environment**.

1918

LIMITS TO PERCEPTION

→ **Perception (Limits to)**

1919

LINEAR²⁾

The property of any **process** or **function** whose increase or decrease follows a simple arithmetical **rate**, i.e. without any **positive** (i.e. accelerating) or **negative** (i.e. braking) **feedback**.

More simply, in a linear relationship "**variables** are increased or reduced by a constant quantity" (ROSEN, 1966, p.93).

Linear relations can be represented by a straight line in cartesian coordinates, which explains the use of this term.

→ **Linearity**

1920

LINEAR BEHAVIOR¹⁾

F. ROBB states: "...linear behavior is not the rule but just one special case of systems behavior in a predominantly **nonlinear** world. The linearities to which we have become so accustomed are the outcome of the use of our bounded rationality, and the tools which supported it, of our **language**, our mathematics, our simple logics and or self-imposed **constraints** such as OCKAM's Razor" (1990, p.137).

1921

LINEAR PROGRAMMING⁵⁾

"A combined analytical and **decision-making** technique based on mathematical programming" (I.G. BLOOR, 1988, p.24).

Linear programming uses algebraic and graphical **methods** in search of the optimal solution.

I.G. BLOOR explains that the aim is to find a suitable **equilibrium** between "**objectives** (e.g. maximize profits, minimize **waste**) and **constraints** (**resources** that are scarce, **time**)". He adds that: "The choice of **method** depends on the number of **variables** under consideration: more than two require algebraic (or computer) solutions".

He states that the technique is usable "... to provide feasible solutions to problems where the alternatives seem infinite or non-existent" (1988, p. 24).

Truly complex **situations** however frequently cannot be treated by linear programming.

1922

LINEARITY^{1) - 2)}

An arithmetical relation between quantities, i.e. characterized by a fixed arithmetic **rate** of increase or decrease.

$y = ax$, is a typical linear relation. Its **representation** is a straight line. It includes only **variables** of the *first order or degree*, affected by some arithmetic coefficient. It is merely **accumulative** at an invariable **rate** and corresponds to a permanent "one cause, one effect" **process**.

Linearity is a property of **processes** exempt of **positive** (accelerative), or **negative** (**dampening**) **feedbacks**. However, a positive or negative acceleration in itself can be linear, as derivation from a linear differential equation.

Truly linear **processes** are exceptional, even if during a limited **span of time**, a **nonlinear** one may look as linear. Trying to study **nonlinear processes** in linear terms is generally to no avail, as very few **processes** are immune to internal and/or external **constraints** expressed through **regulation loops** or **controls**. In such cases linear **models** may lead to gigantic (or subtle, which could be worse) **extrapolation** errors.

1923

LINEARIZATION ²⁾

The approximate **description** of a nonlinear **process** or system through a linear **model**.

Such a **reduction** is possible and useful only when the **behavior** of the modeled system is, for a **time**, only very slightly affected by **non-linear effects** and when there are good reasons to believe that this **situation** could not be suddenly reversed by a **change** in the basic conditions of existence of the system. Any appearing factor of acceleration or slowdown, **possible discontinuity**, or incipient **chaotic behavior** should be closely watched.

In particular, as expressed by R. MAY: "The elegant body of mathematical theory corresponding to linear systems (**FOURIER analysis**, orthogonal functions, etc.) and its successful application to numerous fundamental problems in physical sciences, tend still to dominate more or less advanced universities cursus in mathematics and physics. Mathematical **intuition** thus developed ill prepares the student to confront the strange **behavior** showed by the simplest **nonlinear discrete** systems, while however these **nonlinear** systems are surely the rule and not the exception outside the physical sciences" (1976).

1924

LINGUISTIC CLOSURE ²⁾³⁾⁵⁾

L. LÖFGREN emphasizes the closure character of our **languages** of all kinds, even mathematical or formal. He writes "The systemic **wholeness**, or the complementaristic nature, of the language implies a closure, or circumscription, of our linguistic abilities- be they "pure thoughts" communicable in a formal mathematical language, or constructive directions for an experimental interpretation- domain of a physics language. The nature of this closure is not that of a classical **boundary** of a capacity, like descriptibility, or interpretability. It is a tensioned and hereditary boundary of the systemic capacity of descriptibility- and- interpretability" (2000, p. 17-18)

He explains closure **tension** as the interactive **complementarity** between both capacities, where a better descriptibility somehow limits interpretability.

As to the closure as hereditary, he observes that "...at each **time** we try to communicate... we are confined to a shared language", i.e. the language that we received in its present state (as much as we did receive it) (p. 18)

An excellent example is this very Encyclopaedia: Interpretability can be obtained only by multiple **interconnections** between **description** terms. This is why so many cross-references are introduced.

As to the "hereditary" aspects, the users of the 2nd. edition inherit still a closed linguistic system, but whose **domain** has been much widened.

1925

LINGUISTIC DRIFT ^{1) - 3) - 4)}

The slow and progressive **changes** in **meanings** that affects words and concepts in any natural **language**.

This very significant systemic **transformation** remains mostly unperceived, because it is slow (it is the equivalent for **languages** of the "boiled frog parable").

It can only be observed after various decades, or at least years, and is more easily perceived by someone who returns to his/her own cultural system after a long absence. A similar **phenomenon** occurs in any expanding linguistic area: "Democracy" has not exactly the same **meaning** in Italy, England, United States, Kenya, or Australia. It may also produce misunderstandings, and even **conflicts** when new members in a culture or **organization** bring with them slightly different **meanings**.

J. WARFIELD stresses the importance of this **phenomenon** in **organizations**, where: "As the **organization** grows, linguistic separation grows both laterally and vertically in the **organization**". Particularly: "At higher vertical **levels**, **metaphors** and **categories** become progressively disconnected from the relevant **components** at lower **levels**, leading to **decisions** based on perceived **relations** between **categories** that are not borne out by **relations** between **category** members" (1995, p.129).

Linguistic drift even effect orthography, spelling and pronunciation. A growing number of errors and confusions can be observed nowadays in newspapers, magazines and even technical and scientific journals.

The main causes seem to be:

- interlinguistic contamination due to massive migrations and the wide diffusion of some **languages**, as for instance english as used by non-native english speakers

- the general abandonment (in western countries) of the study of classical greek and latin, as these languages tended to stabilize and standardize linguistic, and even interlinguistic uses

- the progressive **transition** from written and read transmission of **information** to verbal transmission in radio and television

Of course, linguistic drift always existed. This was the way for example how so-called latin languages (Italian, Spanish, Portuguese, Catalan, French, Rumanian) derived differently from latin until the latter became a "dead" language.

The main problem resulting from linguistic drift is **semantic** drift, which is in fact nothing else than the contemporary form of the "**Babel Tower**" effect.

In any way, this **process** is for now fully active in the whole world ...and encyclopedia's editors are in for a rough ride.

1926

LINGUISTIC HEDGE ²⁾

A **fuzzy** quantitative term used to relativize a primary term.

This concept has been introduced by L.A. ZADEH to allow for the **representation** of a degree of linguistic imprecision, according to his basic **concept of fuzziness**.

As examples of hedges he cites: "*very, much, slightly, more or less* (although *more or less* is comprised of three words, it is regarded as an atomic term), etc." (1973b, p.33).

1927

LINGUISTIC VARIABLES ²⁾

According to L.A. ZADEH: "... the ability to summarize **information** plays an essential role in the characterization of complex **phenomena**. In the case of humans, the ability to summarize **information** finds its most pronounced manifestation in the use of natural **languages**".

As a result: "If we regard the color of an **object** as a **variable**, then its values, red, blue, yellow, green, etc., may be interpreted as **labels** of **fuzzy subsets** of a universe of **objects**. In this sense, the attribute *color* is a **fuzzy variable**, that is, a **variable** whose values are **labels of fuzzys sets**", and

"... the main **function** of linguistic variables is to provide a systematic means for an approximate characterization of complex or ill-defined **phenomena**" (1973b, p.29).

Thus, "blue", as a fuzzy linguistic variable, includes light blue, sky blue, Prussian blue, ultramarine, etc... However, with "blue-green", a border **distinction**, we have already a problem.

1928

LINK ¹⁾²⁾

A connection between two **elements**.

Links are probably the most basic features of all kinds of systems from physics to sociology.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Graph theory describes numerous types of links and their more interesting **interconnections**, in **linkages** and gives a good understanding of **networks**

Links are **structural**, but correspond also to **dynamical** features in networks and/or systems. In graphs, this is made clear by giving them an orientation represented by an arrow-head. Structural and dynamical aspects are of course complementary.

→ **Cycle, Feedback, Hierarchy, Node, Process, Small worlds, Structures (organizational)**

1929

LINKAGE²⁾

A characteristic introduced among **elements** pertaining in common to different **parts** of a system.

A. BOGDANOV introduced this concept as early as 1922. He explains: "The linkage of two links in a chain is that part of one link which lay inside of the other; and especially the surface of their contact" (1980, p.69).

He adds: "Linkage denotes the 'entry' of **elements** of one complex into another, and vice versa" (Ibid).

"Complex", in BOGDANOV's terminology may be considered as meaning approximately "**sub-system**".

A linkage implies necessarily a **relationship**, which may appear only **structural**, but is generally a **dynamic** and **functional** one.

1930

LINKAGE PROPOSITIONS³⁾

"A way to connect any two or more **isomorphies** by describing their specific **cross-impact** on each other in a **semantic** sentence" (L. TRONCALE).

Linkages propositions have been introduced by L.R. TRONCALE in 1978 (see 1985, p.43-83), as a **methodology** to produce a better **organization** within the global **set** of systemic concepts and **models**. TRONCALE selected 75 principal concepts (most of them in this encyclopedia) as the basic **set** for the combinatory construction of linkages.

According to TRONCALE, a basic systemic **concept** must be endowed with the following characteristics:

- be at a sufficient **level of abstraction**
- not be anthropomorphic
- offer a phenomenological basis (i.e. be related to **concrete systems**)
- be ana-synthetic (i.e. at least potentially general)
- not be based on **methodology**
- be oriented toward some **process**
- be of use for the reciprocal definition of other basic systemic **concepts**
- allow for extensive **interactions** with other basic systemic **concepts**

- be really **transdisciplinary**
- be useful to clarify systemic **complexity**
- be a prime generator of systemic characteristics.

According to TRONCALE the following types of **concepts** should be avoided:

- terms with (according to him) anthropomorphic undertones as for example **axiology**, **epistemology**, systemic **causality** or systemic **behavior**;
- descriptive or classificative terms as **artificial intelligence**, **dynamic complexity**, systemic **evolution** or **isomorphy**;
- methodological terms as **modelization**, **simulation** or **mapping**.

As no linkage proposition can be totally isolated from **context**, their **validation** by controlled experiments as practiced in hard sciences is impossible.

TRONCALE proposes the following types of linkages:

- **congruent**, i.e. proposing an **isomorphy**, an **analogy**, **homology** or **identity**;
- **linear**, i.e. showing a causal, functional or necessary **interrelation**;
- **reciprocal**, showing a negation, **inhibition**, opposition, increase or decrease;
- **complementary**, marking a **symmetrical** or **complementary relation**.

Using his **methodology** TRONCALE constructs a **matrix** of potential linkages among the **set** of concepts, producing tentative propositions. Each of these must be verified in the major possible number of disciplines. All are of a quite general character as for example: "**Synergy** may result of a consonance of **cycles**". What is hoped for is an interlinked system of systemic concepts: Only the **set** of its linkages properly clarifies the sense of any concept.

TRONCALE enumerates moreover other possible uses of this **methodology**:

- enrich the **meaning** and **understanding** of each basic systemic concept;
- enrich the **understanding** of the origins of the specific **phenomenon** corresponding to each concept;
- enhance the **consciousness** of the dynamic character of systemic **processes**;
- help searching for more **isomorphies**;
- propose better tests of the basic systemic concepts and their linkages;
- enhance the predictive power of general systemic **models**;
- delimit and describe the areas that may require more attention and research;
- provide a **reference frame** to assess the value and the more or less embracing character of proposed **models** and **simulations** for the researched systems.
- offer a precise and efficient tool for teaching **General Systems Theory**.

The general organization of the present work widely takes in account TRONCALE's linkages **methodology** by explaining the **meanings** of terms and concepts through definitions and comments using other related terms and concepts. In this way, an interconnected **net** of **meanings** creates a coherent **semantic space**. However, emphasis is also extended wider afar, in order to connect concepts with **models** and specific disciplines, when needed even when this entails reference to so-called anthropomorphic terms (for ex. **image**, **norm**) or non-systemic abstract ones (for ex. **epistemology**).

1931

LINKS (Weak or strong)¹⁾²⁾

Strong links in systems are quite rigid, as they are difficult to break.

On the contrary, weak links can be easily loosened, but also easily constructed. This is a significant condition for **adaptability** in **complex systems**, from molecules to **brains** and, probably all types of **social systems**. For examples in chemistry, see J. THOMAS (1998)

1932

LINKTHINK^{2) - 4)}

The coordinated and productive mental **activity** in a **group** which has carefully explored the whole field of ideas related to the **issue**, **situation** or **problem** under scrutiny.

J. WARFIELD, who introduced this neologism writes: "With linkthink, members are asked to determine how those ideas that received at least one vote during the **Nominal Group Technique process** are related... This **activity** is carried out using a **methodology** called **Interpretive Structural Modelling**" (J.N. WARFIELD and C. TEIGEN, 1995, p.32).

This **process** of establishing **linkages** can be computer assisted. It normally produces "a graphical **structure** showing how **problems** are interrelated through the **relationship** "aggravates" (Ibid).

In this way a "**Problematique**" is constructed, which represents a global, integrated view of the **issue** considered.

1933

LITHOSPHERE¹⁾²⁾

The solid crust which envelopes the high temperature earth core.

In his ecological **model** of the **man-planet system**, Ch. FRANÇOIS uses the term "geosphere". Clearly the lithosphere includes also the submerged parts of the crust.

→ **Atmosphere; Biosphere; Ekistics; Hydrosphere; Sociosphere; World engine**

1934

LIVING SYSTEMS^{1) - 2) - 4)}

A general theory of living systems has been established by J.G. MILLER, who introduces it in global terms as follows: The general living systems theory... is a conceptual system concerned primarily with **concrete systems** which exist in **space-time**. Complex **structures** which carry out living **processes** I believe can be identified at seven **hierarchical levels**... **cell, organ, organism, group, organization, society**, and supranational systems. My central thesis is that systems at all these **levels** are **open systems** composed of **subsystems** which process **inputs, throughputs** and **outputs** of various forms of **matter, energy** and **information**". (1978, p.1).

At the time, MILLER thus identified **7 levels** and **19 critical subsystems**. More recently J. and J.G. MILLER completed this **taxonomy** by interposing the "**community**", as a supplementary **level** in-between the **organization** and the **society levels** and, on the other hand, one more **subsystem**, the "**timer**", which introduces a general **dynamics** which seemed to be lacking in the first presentation of the theory. (1992)

MILLER pursued in 1978: "I identify **19 critical subsystems**... whose **processes** are essential for life, some of which process **matter** or **energy**, some of which process **information**, and some of which process all three" (1978, p.1)

According to MILLER in his more recent statement, any system at any of the **8 levels** need the same **20 critical subsystems** but: "The **structure** and **processes** of a given **subsystem** are more complex at a more advanced **level** than at the less advanced ones. This is explained by what I call the evolutionary principle of "shred out", a sort of division of labor (as the)... general direction of **evolution** is toward greater **complexity**" (p.1).

For each **subsystem**, MILLER identifies "about a dozen **variables** representing different aspects of its **processes**. It would be easy to identify more if one wanted an exhaustive list. Each of these **variables** can be measured at each of the **levels**, and the sorts of variations discovered can be compared across the **levels**" (p.4).

This feature leads MILLER to his **cross-level hypothesis method** aimed at discovering **isomorphies** between **processes** and/or **structures** at different **levels**.

MILLER also states that "Physiology, biochemistry, genetics, pharmacology, medicine, economics, political science, anthropology, sociology and psychology are all almost entirely relevant. Physical science and engineering also contribute. Logic, mathematics and statistics

yield **methods, models** and **simulations**, including some involving the relatively new approaches of **cybernetics** and **information theory**" (p.4).

Consequently, MILLER's is a strongly integrated and all-embracing systems theory.

From a different viewpoint H. MATURANA states: "A living system is an inductive system and functions always in a predictive manner: what happened once will occur again. Its **organization** (genetic and otherwise) is conservative and repeats only that which works" (1970, as quoted in E.von GLASERSFELD, 1976, p.117).

In other words, it is said that biological systems become **organizationally closed** and thus **autopoietic**.

Still from another angle, A.S. IBERALL states: "... a living organism is a working **thermodynamic engine** during its entire life phase" (1973, p.4).

It is also a part of LOTKA's **world engine**.

It should however be noted that the living system is submitted, as shown principally by I. PRIGOGINE, to **specific thermodynamic laws** which allow it to organize itself in apparent contradiction with the 2d.law and to maintain itself as an island of **organization** during its whole life. The price is, however, an acceleration of the increase of **entropy** in the **environment**.

This is still more so for **self-organizing human groups** and **societies**, composed of living systems.

LIVING SYSTEMS: The 8 levels of complexity^{*}

J.G. MILLER defines a **hierarchy** of 8 basic types of living systems in order of growing **complexity**. Every **level** is made of **elements** of the immediately inferior **levels of complexity**. However, all of these are ordered in **20 critical subsystems**, i.e. they are not merely unordered **congeries**.

The first three **levels** are biological: The **cell**, the **organ** and the **organism**.

The fourth, i.e. the **group**, is an ordered reunion of **organisms**, and intermediate between the biological and the (human) social **level**. MILLER did not consider the case of social insects or plant **colonies**.

The last four **levels** are social: The **organization** (e.g. an enterprise), the **community** (e.g. a town, or city), the **society** (a state) and the **supranational system**. (the numerous and more or less connected international agencies: U.N., UNESCO, UNEP, WHO, FAO, etc. (1993, p.158).

In his first versions of "Living systems" (1965, 1978), MILLER described only seven **levels**. The new **level** he introduced is the "**community**", mediatory between the **organization** and the **society**. His **model** for the supranational system was the European Community, as it was in 1978.

One wonders if the eighth level should not be the man-planet system, whose **subsystems** would be the various international **organizations** formerly mentioned, and others instances still to be created. Could the Internet not become for ex. the communication subsystem of the planetary system?

LIVING SYSTEMS: The 20 critical subsystems

See the complete listing under: "**Subsystems**" and each specific type of **subsystem** under the corresponding alphabetic listing.

1935

LOCALITY^{1) - 3)}

The hypothesis according to which no **element** or system can exercise an unlimited **action** at distance, and still less so, an instantaneous one.

Or "The **dominance** in a limited **region of space** of specific conditions of **interactions** among **elements**".

It is finally amazing to note how many shades of **meaning** such an apparently clear **concept** can evoke.

D. TSAGDIS, for instance, writes (in a footnote!): "Locality is semantically over-loaded. It can refer, for example, to: a Cartesian spatio-temporal **space**, a Husserlean **experiential region**, a Heideggerian horizon, a Wittgensteinian **language game**, and/or their syntheses. A more helpful way of understanding such a rich notion is to conceptualize it as constituted by the four sources of observational **error**, viz. **observer, context, object, language**.

This would be a "richer" or, dare I say, more complex locality constituted with all four sources of error..." (2002, p. 152)

In other words, **fields** are not infinite and, in accordance with relativity, the light's propagation velocity cannot be surpassed.

This hypothesis seems now to compete with D. BOHM concept of **non-locality**. This could lead to a deep reevaluation of many scientific concepts.

→ **Energy; Matter; Perceptual field; Space; Time**

1936

LOCALIZATION²⁾

W.R. ASHBY explains how, in the nervous system, **perceptive dispersion** allows for a measure of localisation in cerebral activity, which insures the **heterogeneity** needed within any **complex system** (1960, p.178-80).

He however quotes LASHLEY, who remarked "...that the **memory-traces** might be localised individually without conflicting with the main facts, provided there were many traces and that they were scattered widely over the cerebral cortex, unified functionally but not anatomically" (Ibid., p.183).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Such a kind of "untidy" localisation in the cerebral **network** is neither rigorously **deterministic**, nor totally **random** and combines the advantages of ordered **organization** with those of scattering which offers possibilities of numerous new recombinations.

1937

LOCATION¹⁾

A precise site in a **space-time** slice that is sufficient to individualize some **entity** at a given moment.

Locations in **space** are necessarily correlated to moments in **time**.

1938

LOCATIONAL DECOMPOSITION^{2) - 3)}

"The conceptual separation of **parts** of a system according to their relative **locations** within a continuum of **space** and/or **time**" (N. TODA & E. SHUFORD, 1965, p.26).

The authors obviously introduce the word "conceptual", as any decomposition is – more or less – a result of the **understanding** of the **observer**.

1939

LOCK-IN EFFECT^{1) - 2) - 3)}

A condition in which some previously acquired characteristic in a system blocks further **changes**.

Existing **situations** tend to create "**frozen cores**" within systems. This is frequent in technical devices, as observed for instance by S. J. GOULD, who describes the way the old QWERTY keyboard blocks since many years the introduction of better keyboard designs (1991). It also may be the cause that slows or blocks for long time new scientific **paradigms**. For instance, one may think that the global view proposed by **systemics** is thus blocked by the dominant specialized approach.

The anonymous peer review system is instrumental in producing lock-in effects against scientific innovations, according to A. BEREZIN et al. (1995).

1940

LOCK-IN EFFECT¹⁾²⁾

The way a system becomes more or less **irreversibly** dependent on its former **adaptations**

This is a universal effect, from oxygen dependence for breathing of superior animals (which is absolute) to the strong dependence of modern transportation on non-renewable fossil fuels as their source of **energy**.

The lock-in effect may easily become dangerously critical and its possibility should be carefully evaluated when some new adaptation is considered.

This is why the principle that "**fit** is not forever" is important and also why **adaptability** is to be always maintained as much as possible.

→ **Caution principle**

1941

LOGARITHMS: Their use in information theory⁵⁾

Dual logarithms (i.e. to base 2) are a measure of the number of **binary decisions** (**BITS** = binary digits) needed to suppress **uncertainty** in a **situation**.

Log₂N also measures ASHBY's **variety**, as indicating the number of successive **choices** to be made in order to obtain a precise **distinction**. ASHBY gives the following example: "What is the **variety** in **bits** of the 26 letters of the alphabet?" The reply is 4,7 **bits**, i.e. in practice 5 successive **choices** to be made to completely determine the position of one specified letter within the English alphabet, using yes or no answers to questions like: Is it in the first half of the alphabet? Is it in the 2nd half of the first half?, etc.

1942

LOGIC : A Critical View³⁾

G. BATESON states that "Logic is a poor **model** of **cause and effect**" (1979, p. 58)

He observes that we are mistaken when "we use the same words to talk about logical sequences and about sequences of cause and effect" (Ibid)

In fact, the difference is that the cause-effect sequence exist in the **time dimension**, while the logical one is a timeless abstraction. Or, in other words, the cause-effect sequence is considering **events**, and thus energetic **transformation**, while the logical sequence is merely a quite limited- and in a sense, static- model of **linear causality**. In particular, it ignores closed loops brought about by **feedbacks**.

This is noteworthy, since we had to wait until the 20th C. to discover that the fabled implicit contradiction in the famous sentence: "Epimedes the Cretan says that all Cretans are liars", contains in fact a feedback which is the cause of the irreducible **ambiguity**.

→ **Types (theory of logical)**

1943

LOGIC AND CULTURE³⁾⁴⁾

M. MARUYAMA states that different cultures tend to adhere to different types of reasoning (1994, p. 2-4)

As an example: "the logic that is taught in European and North American schools is called "Aristotelian logic", or "Cartesian logic", named after Aristotle (384-322BC), the Greek philosopher, and Descartes (1596-1650), a French philosopher. It is also called "Von Neumann logic" by computer people. It is based on classificational and hierarchical thinking, and it

denies the possibility that many things can cause one another". This is of course the root of rigorous **linear causal determinism**, which still dominates most of western thought.

However other views exist in other **cultures** and even within western cultures some individuals share them. **Cybernetics** for ex., by introducing **feedbacks** (**positive** or **negative**) is bending **deterministic causality** onto itself, so to say.

More recently determinism has turned "**chaotic**", when it became clearer that any **event** is in fact the complex result of a twisted and complex **set** of causes concurring to shape some present **event**.

Maruyama writes that the cybernetic view, and other ones have existed and still exist implicitly in various non-western cultures and that in every **culture**, "in any society at any time there is **heterogeneity** of logics among individuals" (Ibid). However one specific type of logic normally becomes dominant in a culture.

Nevertheless, the existence of individuals of other types in the culture always opens the way for possible switches.

→ **Mindscales**

1944

LOGIC AS A METAPATTERN³⁾

T. VAMOS et al, who consider that **patterns** that we perceive or define (constellations of stars for example) are basically **metaphors**, resulting even in some cases from the phylogenetic **evolution**.

They go still further and write: "Logic as a high development of this **evolution** is a meta-pattern itself, a **pattern** of some regular **pattern** relations" (1992, p.1609).

This is an interesting idea, if one considers the extensions of logic during the 20th century under the impact of some perceived contradictions and imperfections within the limits of traditional logic.

1945

LOGIC (Structure of)¹⁾³⁾

According to K.L.von BERTALANFFY: "It may be that the structure of our logic is essentially determined by the structure of our central **nervous system**. The latter is essentially a **digital computer**, since the **neurons** work according to the **all-or-nothing** law of physiology in terms of yes-or-no **decisions**. To this corresponds the Heraclitean principle of our thinking in opposites, our bivalent yes-or-no logic, **Boolean algebra** and the **binary** system of numbers to which also the practically more convenient decadic system can be reduced (and is actually reduced in modern calculating machines)" (1962b, p.245)

Thus our way to perceive and make **models** of the outside world seem to be closely dependent of our physiology.

1946

LOGICAL DEPTH⁵⁾

"The amount of **time** it would take a computer to generate a **simulation** of a system".

This definition is due to Ch. BENNETT, as quoted by J. HALLIWELL (1995).

This is of course a **binary** logic feature.

1947

LOGICAL OPERATIONS (Basic)^{3) - 5)}

"And" and "or" are the basic **operations** of logic. Together with "no" (the logical **operation** of negation) they are a complete **set** of basic logical **operations** - all other logical **operations**, no matter how complex, can be obtained by suitable combinations of these" (J.von NEUMANN, 1958, p.53).

These logical **operations** correspond to **binary logic** and are directly derived from G. BOOLE's "Laws of thought" (1854, reprinted 1952). They can be easily represented by **VENN diagrams**, now **fractalized** by A. EDWARDS (1989).

1948

LOGICAL TYPES (THEORY of)³⁾

The theory of logical types was established by B. RUSSELL and A.N. WHITEHEAD in their "PRINCIPIA MATHEMATICA".

G. BATESON synthesized it as follows: "... the theory asserts that no **class** can, in formal logic or mathematical discourse, be a member of itself; that a **class** of **classes** cannot be one of the **classes** which are its members; that a name is not the thing named..." (1973, p.250).

As expressed by G. BATESON (1979, p.229): "A series of examples is in order:

1. The name is not the thing named but is of different **logical type**, higher than that of the thing named.

2. The **class** is of a different **logical type**, higher than that of its members.

3. The injunction issued by, or **control** emanating from, the bias of the house thermostat is of higher **logical type** than the control issued by the thermometer. (The bias is the device on the wall that can be set to determine the temperature around which the temperature of the house will vary).

4. The word "tumbleweed" is of the same **logical type** as "bush" or "tree". It is not the name of a species or genus of plants; rather, it is the name of a **class** of plants, whose members share a particular style of **growth** and dissemination.

5. Acceleration is of a higher **logical type** than velocity"

The theory of logical types was established in order to eliminate logical paradoxes whose best known example is the assertion by EPIMENIDES *the Cretan* that all Cretans are liars, a self-contradictory statement.

In R.von MISES words: "It constitutes the first step toward a general rational conceptual **structure** and discards old pseudo problems".

It has an obvious relation to **GÖDEL's incompleteness theorem**, and far from having only abstract bearings, it is very useful to clear logico-semantic muddles and many innocently or artfully distorted pseudo-logical arguments, for example in psychology.(1973, p.250 - 279).

It is a necessary tool for the establishment of **hierarchies of isomorphisms in General Systems Research**.

1949

LOGICO-MATHEMATICAL LANGUAGE (Meaning in a)³⁾

Logico-mathematical languages are unambiguous.

H. ATLAN writes: "There is a one to one correspondence between the **symbol** and its meaning but at the same time, as a formal language, it can exist as a **structure** of **symbols** without them having any **meaning**; in other words, whenever the language reaches the state of having non **ambiguous** meanings, it can be formalized and exist without any **meaning**." (1972, p.246).

Of course, this should be understood as "without any specific or concrete **meaning**."

1950

LOGISTIC EQUATION^{2) - 5)}

The logistic equation was introduced in 1838 by the Belgian demographer L. VERHULST. It is generally written in two different forms:

$$(1) X_{n+1} = aX_n (1 - X_n) \text{ or} \\ (2) X_{n+1} = aX_n - aX_n^2$$

The aX_n^2 member expresses the progressive braking effect on **growth** due to some inherent **constraint**, activated by the systems or **process growth** itself. Generally speaking, this **constraint** is the rarefaction of the basic **resource** that feeds the system or **process**, due to its growing consumption.

As observed by C. MARCHETTI, quoted by J. CASTI, this logistic growth is characteristic of the **evolution** of any type of **populations**, even in "psychological, social, technological and political **phenomena**" as for example MOZART's musical works, construction of Gothic cathedrals in Europe and the volume of world airline traffic" (1994, p.37).

The braking factor can be nutrients, available **space**, overextension of **communication** lines or some **limit** of the brain's **network combinatorics** capacity.

1951

LOGISTIC EQUATION AND CHAOS^{2) - 5)}

Curiously, the logistic equation has been studied during more than one century and put to considerable uses, before anybody noted its

strange properties for higher values of the coefficient a . (See for example A.J. LOTKA, 1956, and V. VOLTERRA's, 1931 works).

However, some aspects of **populations** dynamics remained unexplained by the equation and this fact was more than once attributed to some insufficient **data** or statistical errors.

More recently, it has been discovered that, as stated by R.V. JENSEN: "The **time-evolution** of x_n , generated by this single algebraic equation exhibits an extraordinary **transformation** from **order** to **chaos** as the **parameter** a , which measures the **strength** of the **nonlinearity**, is increased... In fact, the review article on the logistic map by the biologist Robert MAY (1976) is a historical milestone in the modern development of **nonlinear** dynamics" (1987, p.170).

This **chaotic randomness** of the logistic equation, once a specific **threshold** is crossed, is explained by J. CASTI as follows: "When we put the birth and **overcrowding effects** together into a single expression, what pops out is the formula for **randomness**" (1990, p.94).

Moreover, as **overcrowding** results of an excess in **inputs**, this feature of systems becomes related to PRIGOGINE's **thermodynamics of systems far-from-equilibrium**, submitted to giant **fluctuations**.

Grounding his analysis on the quadratic form (2) of the logistic equation, JENSEN writes: "When the original **population** X_0 is small (much less than 1 on a normalized scale, where 1 might stand for any number, such a 1 million individuals), the **nonlinear** term can initially be neglected. Then the **population** at time-step (year) $n = 1$ will be approximately equal to aX_0 . If $a > 1$, the **population** increases. If $a < 1$, the **population** decreases. Therefore, the **linear** term in equation (1) can be interpreted as a **linear growth** or death **rate** which by itself would lead to **exponential population growth** or decay. If $a > 1$, the **population** will eventually grow to a value large enough for the **nonlinear** term $-aX_n^2$ to become important. Since this term is negative, it represents a **nonlinear death rate** which dominates when the **population** becomes too large" (1987, p.170).

So far, so good.

However, while the "...graphic analysis tells us that if the normalized **population** starts out larger than 1, then it immediately goes negative, becoming extinct in one time-step" (Ibid.); for values of a between 0 and 4, "Conventional **perturbation** theory gives no hint of the existence of a nonvanishing **steady state population**" (p.171).

"For values of a between 1 and 3 almost all initial **populations** evolve to this **equilibrium population**" (See **asymptotic stability**). "Then, as a is increased between 3 and 4, the **dynamics** change in remarkable ways. First, the fixed point becomes unstable and the **population** evolves to a **dynamic steady state** in

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

which it alternates between a large and a small **population**... (a **period-2 cycle**). For somewhat larger values of a this **period-2 cycle** becomes unstable and is replaced by a **period-4 cycle** in which the **population** alternates high-low, returning to its original value every four time-steps. As a is increased, the **long-time** motion converges to **period** -8, -16, -32, -64 **cycles**, finally accumulating to a **cycle** of infinite **period** for $a = a_{\infty} 3,57$ " (Ibid.) In other words, at this value, **chaotic stability** is achieved and for higher values of a the **evolution** of **populations** "... is indistinguishable from a **random process**, even though the logistic map is fully deterministic in the sense that there are no "random" forces and that the future is completely determined by the **initial condition**, X_0 .(p.171).

This is an absolutely general property of the logistic equation, for any kind of **populations** and is thus a general systemic property.

1952

LOGON ³⁾ - 4)

"The unit of **structural information** is that which enables one such new distinguishable group to be defined for a **representation**." (D. GABOR, as quoted by D.G. Mac KAY)

Mac KAY, who adapted GABOR's concept, comments:

"Thus **structural information** is not concerned with the *number* of **elements** in a **pattern**, but with the possibility of distinguishing between them" (1969, p.165).

This is the same characteristic difference which exist between **homogeneity** and **heterogeneity**, in **space** as well as in **time** as the following example given by MacKAY expresses:

"...if we are counting identical sheeps jumping through a gate, and we have no sense of **time**, our result can only be represented by a certain total number; but if we have a clock we can now define what we mean by "the number in the first minute" and "in the second" and so forth, and represent our result by a set of *distinguishable* subtotals. The clock has provided **structural information**. In a similar way the ability to distinguish (e.g) spatial position along the gate would provide distinguishable subtotals and hence increase the **structural information-content** of our **representation**" (p.165).

1953

LOGON CONTENT ³⁾ - 4)

"The **structural information content** or number of logons (number of independently variable features) in a **representation**" (D. Mac KAY, 1969, p.165).

As an example, Mac KAY gives "the number of independent coefficients required to specify a given waveform over a given **period of time**" (Ibid).

One should possibly further extend the concept of logon. G.R. JOHNSON observes that: "(The) **content** (of an **information**), whether contained in an act of speech or "processed" by a nervous system, can only be inferred from the linguistic and other **behaviors** of humans", and... "... deaths threats are not equivalent to marriage proposals, even if they contain the same number of **bits of information**" (1992, p.1148).

1954

LOOP ¹⁾ - 2)

A closed circular **interconnection** between two or more interacting systems or **subsystems**, allowing for the **emergence** of a **positive** or **negative feedback**.

Loops are necessary for any type of **regulation** or **control**. In the case of **positive feedback** loops, that creates **heterogeneity**, M. MARUYAMA observes: "There are qualitative aspects as well: a) the basic principle of social, biological and even some physical **processes** is increase of **heterogeneity** and **interaction** among **heterogeneous elements**; in these **processes**, **heterogeneity** is necessary and desirable; b) qualitative improvements occur, such as **evolution**, as a result of **heterogenization**; c) genuine new **patterns**, not new combinations of old **patterns**, arise from **interaction** among **heterogeneous elements**" (1994, p.79).

1955

LOOP CIRCUIT ¹⁾ - 2) - 4)

A systemic **control** device which recycles materials and rewards and stimulates **parts** in proportion to their effectiveness (adapted from H. ODUM, 1971, p.150).

ODUM states: "Either too much or too little **growth** by one **component** puts the loop out of harmonious **flow**" (Ibid).

Any **complex system** - biological, ecological, economic or political - must be and remain **balanced**.

Unfortunately, in some cases they are not and man aggravates many systemic problems by unwittingly creating not sustainable disbalances, i.e. breaking loop circuits.

1956

LOOP (Self-replicating)→ **Self-replicating loop**

1957

LOOP (Self-reproducing) ²⁾⁵⁾

The self-reproducing loop - discovered by C. LANGTON - is, to date, the simplest **cellular automaton** able to reproduce its own **form** and propagate in an **isotropic space**.

For a short description, see C. EMMECHE (1994, p.59), after C. LANGTON original paper (1984, p.135-44).

→ **Garden of Eden**

1958

LOOP (Sensory-motor)→ **Sensory-motor loop**

1959

LOOP STABILITY ²⁾

J. MILSUM states: "... the particular dynamics and **parameter values** of the loop... are critically important in determining its **stability**" (1968, p.46).

Either **positive** or **negative feedbacks** may, in the long run, destabilize a loop and, finally, destroy it. A reiterative and not compensated **positive feedback** leads to a destructive **run-away event**: an out of order thermostat may induce a fire, which will destroy the **regulation** loop.

A not compensated **negative feedback** finally annulates any **regulation** and drives the loop out of existence: once past a certain point of **decay**, the renewal **cycle** of a **population** may disappear (and the **population** together with it).

1960

LOOPS (Causal) DIAGRAM ¹⁾ - 2)

A **graph** representing the **interconnections** between causes and **effects** within a **complex system**.

Complex **nets** of loops can be represented by **oriented graphs**.

Such **graphs**, proposed by M. MARUYAMA include through a convenient notation system, the directions of influence, **amplitudes** and **time delays**.

MARUYAMA justify the necessity as follows: "Use of sophisticated computer **simulation programs** remove **strategy decision makers** from direct comprehension of **interrelations** among key **variables**, because it suffices for the **program** user to look at the **input** and the **output** without knowing what takes place in the **program**" (1992, p.37).

In such a **situation** the **decision maker** may easily ignore if the **program** really represent what is going on in the **concrete system**... and even in some cases, does not possess himself a clear **understanding** of the same.

MARUYAMA, by introducing **time delays**, gives a dynamic character to his diagrams. Moreover: "**Adjustment of time delay** in one **element** to increase or decrease change **amplification** of a loop is an example of **action** suggested in the preliminary causal loop diagram analysis" (p.38).

In short, these diagrams are very useful thinking devices for managers and generally for all participants in the **organization**.

1961

LORENZ's BUTTERFLY²⁾ – 5)

"The mere flapping of a butterfly's wings could spawn hurricanes after not too long a time and very far away". This image was proposed in the 1960's by E. N. LORENZ, a meteorologist at the M.I.T.

While not utterly impossible, this should of course be taken as a portentous **metaphor** about **chaotic behavior** and high **unpredictability of complex systems**, due to their **high sensibility to initial conditions**.

1962

LUSSER Theorem²⁾

The **probability of resistance** (or **reliability**) of a chain of **components** is the product of the probability of resistance or reliability of all of its **elements**.

This implies that no composite system can be more resistant or reliable than its weakest element.

This property is determinant in the analysis of **failures** in a system.

→ **Failure tree**

1963

LIAPOUNOV EXPONENT²⁾ – 5)

The exponent $1/\tau$ of the function $e^{1/\tau}$ established by LIAPOUNOV.

LIAPOUNOV's exponents express the rate of **separation** or **convergence** of a **dynamic system's trajectories**. "And if either of these numbers is positive, indicating a positive rate of **separation** of the initial points in a given direction, we say that the system is **chaotic**" (J. CASTI, 1990, p.100).

"A negative exponent means **limit cycles** and at least a somewhat regular **behavior**. A positive exponent means **chaos**" (C. ZIMMER, 2000, p.84).

J. GLEICK explains: "The Lyapunov exponents in a system provide a way of measuring the conflicting effects of stretching, contracting and folding in the **phase space** of an **attractor**. They give a picture of all the properties of a system that lead to **stability** or **instability**. An exponent greater than zero means stretching – nearby points would separate. An exponent smaller than zero means contraction... For a fixed-point **attractor**, all the Lyapunov exponents are negative, since the direction of pull is inward toward the final **steady state**. An **attractor** in the form of a **periodic orbit** has one exponent of exactly zero and other exponents... negative. A **strange attractor**... has... at least one positive Lyapunov exponent" (1987, p.252).

In I. PRIGOGINE and I. STENGERS words: "A **behavior** is **chaotic** if **trajectories** starting from points as close as wanted in the **phase space**, move away from each other in **time** in an exponential way. The distance between any

two points belonging to such **trajectories** grows thus in proportion to a function $e^{1/\tau}$, in which $1/\tau$, positive by definition for **chaotic systems** is Lyapunov's exponent and τ Lyapunov's time... After an **evolution time** long in relation to Lyapunov's time, the **knowledge** that we possessed from the **initial state** of the system has lost its **relevance** and does not permit us anymore to determine its **trajectory**" (1992, p.77).

Thus, when τ is positive, it defines **irreversibility in time**, in conformity with the **2nd. Law of thermodynamics**.

M

1964

MACHINA SPECULATRIX²⁾ – 5)

The British neurologist W. Grey WALTER experimented during the fifties with a device which he described as follows: "The machine... is a small creature with a smooth shell and a protruding neck carrying a single eye which scans the surroundings for light **stimuli**. Because of its general appearance we call the genus "Testudo" or tortoise...

"(The device) contains but two functional **elements**: two miniature radio tubes, two sense **organs**, one for light and the other for touch, and two **effectors** or **motors**, one for crawling and the other for steering" (1955, p.126).

The set received its **energy** from two small batteries. WALTER added: "The number of **components** in the device was deliberately restricted to two in order to discover what degree of **complexity of behavior** and **independence** (Note: we should say "autonomy") could be achieved with the smallest number of **elements** connected in a system providing the greatest number of possible **interconnections**.

"From the theoretical standpoint two **elements** equivalent to **circuits** in the nervous system can exist in six **modes**; if one is called A and the other B, we can distinguish A, B, A+B, A>B, B>A, and A.B as possible dynamic **forms**. To indicate the **variety of behavior** possible for even so simple a system as this, one need only to mention that six **elements** would be more than enough to form a system which would provide a new **pattern** every tenth of a second for 280 years – four times the human lifetime of 70 years" (p.126-7).

Machina speculatrix displayed indeed a very complex **behavior** and still more so when two of them were in the **field**, falling even sometimes in a **double-bind behavior**, or appearing to have some degree of self-awareness. WALTER's research was apparently not carried along, but becomes now renewed in the guise

of new experiments on groups of more or less elemental **automata**, endowed with **directive correlations** (see for ex. J. ERCEAU, & J. FERBER, 1991).

1965

MACHINE¹⁾ – 2)

1. Anything "which behaves in a machine-like way, namely, that its internal **states**, and the **state** of its surroundings, defines uniquely the next **state** it will go to" (W.R. ASHBY, 1981, p.53).

2. "A set of material **elements** disposed in such a way to permit the execution of some definite **operation**" (L. COUFFIGNAL, 1951, p.17).

COUFFIGNAL distinguished:

"**Natural machines**: Machines composed of **organs** of living beings" (Ibid).

To talk about "Natural machines" seems inconvenient, since it tends to perpetuate the strong dominance of the mechanistic **model** of nature.

Even so, the **metaphor** is still very strongly sustained, as shown by the following (1984) text by J.L. DENEUBOURG et al: "The ants' nest seems to be like a machine which has no **breakdowns** and which is remarkably adaptable thanks to its **design**. A machine like this only needs to be partially programmed, since its **programme** organises itself".

Of course, "nobody" designed the ants' nest, nor wrote down a **program** for it. The authors concedes as much: "... when you observe an ants' nest, you can't help but think that it embodies another solution: that of **self-organization**".

They moreover observe: "In a world which lays more and more value on machine **autonomy**, subservient systems designed to process larger amounts of **information** evermore rapidly provide an initial answer". They conclude that both solutions "will perhaps be complementary in the post-industrial culture" (Ibid).

The still unsolved problem is how to find a way to let the various **subsystems** interact *simultaneously*, in real time, allowing for *some* more or less **deterministic chaotic behavior** without sinking into total incoherence, i.e. how to **organize emergent organization** at the global system level.

"**Artificial machines**: (according to COUFFIGNAL): "Machines constructed by man, for the **purpose** of replacing him in some **action**".

He adds: "We may agree that the lack of any qualificative means "artificial machines", i.e. machines in the older sense" (Ibid).

The artificial machine must be *constructed*, i.e. structured according to a project or **program** and its use depends in turn on a **functional program**. Apart from wear and tear, or

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

being *out of order*, which are limitative degradations of **structure** and **function**, it cannot produce any new and original **behavior** and has no **self-reproduction** capacity.

Further on, COUFFIGNAL writes:

"As we have seen, it is from the artificial machines towards the natural ones that, in most cases, a partial **similarity** will be extended, when found out. Let us remember, to use a precise terminology, that an artificial machine, constructed in view of applying the analogic **method**, is a mechanical **model**" (p.19).

As an historical example, COUFFIGNAL explains the artificial nerve, constructed by Ralph LILLIE in 1922, whose **behavior** led physiologists to admit that the transmission of nervous influx is a physico-chemical **phenomenon**. This conclusion has been widely confirmed by neurology before and after COUFFIGNAL's paper (1951).

However, as COUFFIGNAL still states: "...analogy must be applied mainly to **functional similarities**, and in a lesser fashion, to **similarities of organs** (p.21).

In any case, one wonders if, for many people, the **machine analogy** is really more than a frequently quite feeble **metaphor**, imprudently used.

To put some order and avoid dubious **isomorphies**, it is possible to establish a comparison between specific characteristic of so-called "natural" machines and artificial ones.

NATURAL	ARTIFICIAL
Can generally compensate partial failures	Stops functioning if some element breaks down
Cannot be reconstructed if taken apart	Can be reconstructed if taken apart
Can reproduce its own parts at least up to a point	Is not able to reproduce its own parts
Has autonomy , i.e. is able to compensate up to a point environmental variations.	Is totally dependent of its environment .
Can adapt and evolve by itself	Can merely be programmed, controlled and steered.

According to H. ATLAN "...a machine can be formally defined in the most general possible way by a **set E** of internal **states** and a set **I** of **inputs**. The machine's working is the way by which the **inputs** and internal **states** at a given moment **determine** the internal **states** at the next moment...

"We speak of **self-organization** in a strict sense, if the machine is able to change itself its **function F**, without any **environmental** interference, in such a way as to become ever better adapted to its own aim.

"Would this be possible, it would mean that **F** does modify itself" (as an **exclusive** consequence of the **set** of its internal **states**) (1972, p.25).

Such a conclusion could not easily be sustained. Indeed, in this case, the "machine" would be an **isolated system**, rigidly submitted

to the **Second Principle of thermodynamics**, and the progressive increase of produced **entropy**, not compensated, would lead it to total disorganization.

Besides, the machine as described by ATLAN, is strictly **deterministic**. Thus, it cannot be a satisfying **model** for **complex systems** and we should remain very careful with the "machine" **metaphor**, as used at least since the 17th. century.

1966

MACHINE (Determinate) ²⁾

"That which behaves in the same way as does a closed single-valued **transformation**" (W.R. ASHBY, 1958, p.24).

ASHBY explains: "The series of positions taken by the system *in time* clearly corresponds to the series of **elements** generated by the successive **powers** of the **transformation**. Such a sequence of **states** defines a **trajectory** or **line of behavior**... Next, the fact that a determinate machine, from one **state**, cannot proceed to *both* of two different **states** corresponds, in the **transformation**, to the restriction that each **transform** is single-valued" (p.25).

Determinate machines are **trivial** in von FOERSTER's sense, i.e. their **behavior** is perfectly predictable.

1967

MACHINE (Finite state) ¹⁾²⁾

"Any device that has a specific number - i.e. a finite number - of possible conditions" (M. CAUDILL, 1992, p.46).

M. CAUDILL writes: "The best everyday example of a finite **state** machine is a traffic light. A simple traffic light can be in any one of four possible **states**. There are no other possible

Figure: see entry **Machine (Finite states)**

states for that traffic light ... It never, for example, has all three lights on... Each of the three lights is either on or off, and each of the **states** is well defined and predictable. Furthermore well defined **transitions** exist between the **states**" (p. 46).

In this precise case, it should be added that the different **meanings** attached to the different **states** results of a significant **semantic code** that must be learned independently.

see figure below

1968

MACHINE METAPHOR (The) and its Mechanic ³⁾

In his book "Order and Life", J. NEEDHAM describes the ultimate **mechanicism** subjacent in DRIESCH's **vitalistic** biology. He writes "...it was DESCARTES who introduced the practice of calling **organisms machines**, and then postulating transcendent mechanics to drive them" (1958, p. 74)

Of course, in the western **culture** setting, a unique transcendent Mechanic is finally postulated. This is in deep harmony with monocausal **determinism** and the concept of a pyramidal (and generally autocratic) **model of hierarchy**.

One of the most subtle and deepest conceptual mutation of the 20th C. thought has been the recognition of multi-causal (and ultimately **chaotic**) **determinism** and **network causality**. It is not to say that simple determinism and hierarchical **organization** should be excluded. but they must obviously be inscribed within the more general views as specific and special cases.

The progressive evolution of biology from mechanicism, to **vitalism** and, further on, to the **organismic** view (as proposed by WOODGER and BERTALANFFY among others) testifies

from: CAUDILL, Maureen: "In our Image" - Oxford Univ. Press, New York, Oxford, 1992

to the progressive shift away from the machine metaphor to a more **holographic** one. Let us however beware of possible restrictive effects of an eventual abuse of a dogmatic pure **holistic** view, carrying along the ghost of the "mechanic"

1969

MACHINE (Non-trivial) ²⁾ - ³⁾

A machine whose **behavior** may change in a non-predictable way.

H.von FOERSTER states: "The great difference between **trivial** and non-trivial machines consists in that these latter depend of their internal conditions at different moments, which themselves have been influenced by former operations" (1992, p.62).

According to von FOERSTER, non-trivial machines are:

- globally **determined**
- analytically **undeterminable**
- depending on their past
- non-predictable

In most recent terms, they are **ergodic**, or downright **chaotic**.

von FOERSTER also writes: "(Non-trivial machines) **input-output relationship** is not **invariant**, but is determined by the machine's previous **output**. In other words, its previous steps determine its present **reactions**. While these machines are again **deterministic** systems, for all practical reasons they are unpredictable: an **output** once observed for a given **input** will most likely be not the same for the same **input** given later" (1981, p.201).

This description corresponds to evolving and in some measure to adapting systems and to **deterministic chaos**.

Applying the triviality concept to **living systems**, von FOERSTER states: "Instead of searching for **mechanisms** in the **environment** that turn **organisms** into trivial machines, we have to find the **mechanisms** within the **organisms** that enable them to turn their **environment** into a trivial machine" (1981, p.171).

There seems to be a kind of trade-off between organized systems and their **environment**. **Complexity** of the first tends to trivialize the second. This seems related to the **2d Principle of thermodynamics** and the increasing **entropy** emission by **complex systems** into their **environment**.

1970

MACHINE (Recursion) ²⁾

A machine able to pick up and understand its own **outputs**.

This is the basic condition for **organizational closure**. It means that once an impulse has entered the machine, it remains active – or potentially active – within it through a defined **op-**

erator. The **action** of the **operator** on the initial impulse generates a **meaning**. Various **operators**, when conjugating their **action**, may generate a behavioral **algorithm**.

von FOERSTER, quoting PIAGET, reminds us that **action** is a pre-condition for **perception**, while in turn **perception** becomes a pre-condition for new **action**. There is a kind of upbuilding **circularity** – or better, *spirality* – of the cognitive **process**.

Moreover, it seems that the whole universe of evolving systems could be viewed as a multi-level **embedding** of recursive machines.

→ **World engine (A. LOTKA)**.

1971

MACHINE (Sequential) ²⁾

According to S. LIPSCHUTZ, a complete sequential (or finite **state**) machine "... consists of five things:

- A finite **set A** of **input symbols**
- A finite **set S** of internal **states**
- A finite **set Z** of **output symbols**
- A next-state **function f** from $S \times A$ into S
- An **output function g** from $S \times A$ into Z " (1976, p. 124).

Compare with the **finite automaton**, which modifies its internal **states**, but produces no **outputs**.

1972

MACHINE (Social) ²⁾ - ⁴⁾

This concept is discussed by J.L. VULLIERME, who states that: "If one day really thinking artificial machines should appear, they will necessarily be socialized machines, able to communicate with other machines, in order to construct their own **references**, through cross-referencing with others" (1990, p.153).

This emphasizes **emergence** through interacting **combinatorics**, i.e. **networking**, which seems to be the very basic bedrock of social **efficiency**.

It could be said that any **society**, of any kind, is somehow similar to a **connection machine**.

1973

MACHINE (Trivial) ¹⁾

A machine whose **behavior** does not change in **time**.

H.von FOERSTER warns that: "The term "machine" in this context refers to well-defined functional properties of an abstract entity rather than to an assembly of cogwheels, buttons and levers, although such assemblies may represent embodiments of this abstract functional entity". He adds: "A trivial machine is characterized by a one-to-one **relationship** between its "input" (**stimulus, cause**) and its "output" (**response, effect**). This invariable **relationship** is "the machine". Since this **relationship** is de-

termined once and for all, this is a **deterministic** system; and since an **output** once observed for a given **input** will be the same for the same **input** given later, this is also a predictable system" (1981, p.201).

The basic characteristics of a trivial machine are the following:

- it is fully **deterministic** or **behavior** programmed
- it has a limited number of possible **states**
- its **behavior** is completely predictable
- its **behavior** does not depend from the whole **set** of its past **states**
- it has no **autonomy**
- it cannot self-organize

Until now most human-constructed machines are trivial. von FOERSTER observes jokingly that, according to the famous **Laplacian deterministic** formulation, the world would be a trivial machine! (1992, p.62).

1974

MACHINE-LEARNING SYSTEM (Elements and Basic Functions of) ⁵⁾

T.ÖREN describes the elements and basic functions of such a machine, as follows:

ELEMENTS	BASIC FUNCTIONS
Knowledge acceptor (of exogenous and endogenous knowledge)	Knowledge acquisition from the environment or from the system itself (for self-monitoring systems)
Knowledge operationalizer	Knowledge transformation for knowledge internalization (or operationalization)
Postprocessor of learned knowledge	Enhancement of learned knowledge: Organization Transformation Evaluation
Memory unit	Knowledge storage
Knowledge locator	Finding knowledge relevant to a task
Performance element	Use of the learned knowledge to perform a task

(1990, p.23).

While one must be careful using certain terms (as for example "**memory**"), it is interesting to see, how, as time goes on, the "machine" on its ways towards "intelligence", acquires the same (or similar) **functions** as natural intelligence... or how we are learning about the second one by studying the first one.

Let us remember anyway that ÖREN tends to assimilate "**knowledge**" with "**information**" and that **knowledge** is used in this context in the sense of what an **expert system** contains and how it can be used: see B. ZEIGLER on "internal **representation**" (1976).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

1975

MACRO-, MEGA-, MICRO-^{2) - 3)}

There is much imprecision and even some confusion in the use of these prefixes. S. ARIETI, for example, define the "mesocosm as a world of middle dimensions" and adds: "... life exists in the mesocosm. In order to originate and evolve it had to incorporate mesocosmic laws" (1965, p.114).

ARIETI thus senses that we are somewhere near the middle of the magnitude's **scale**, let us say in between the cosmos and the quarks. Could this not be the superlative form of anthropocentrism?

J.de ROSNAY calls "**macroscope**" the conceptual "instrument" that he proposes to use to observe ARIETI's mesocosm.

We should try to unify terminology and not create too many competing terms. This author proposes to abandon "mesocosm", which never entered common use since 1965 and to use:

- micro- for those **levels** that must be indirectly observed with the help of microscopes, Geiger counters, etc.
- macro- for our natural **level** of **observation** through our senses;
- mega for those **levels** that must be indirectly observed through telescopes and astrophysical instruments... or studied on basis of very general and long-term **observations** and theories.

Micro-, macro- and mega- also define **levels** of **aggregation** or **disaggregation**, as for example macroeconomics versus microeconomics, or macrobiology vs microbiology.

Such a scale is useful in dynamics, helping us to understand the existence of **short, medium** and **long-term processes** and the way the first ones are **embedded** within the last one. Of course, this **scale** is anthropocentric. We merely need to be conscious of this, in order to perceive and understand the relativity of our spatial and temporal **perceptions**.

1976

MACRODETERMINACY^{1) - 2)}

"The situation which occurs in a system that may be treated as **deterministic** at the higher **levels** (or at the **level** of the **whole** itself) but where the lower-order **components** of the system may not admit to **determinacy**" (adapted from J. SUTHERLAND, 1973, p.42).

SUTHERLAND comments: "... this may mean that the system itself is capable of **prediction** (or amenable to some sort of **finite-state system analysis** technique) even though we cannot treat the **parts** or lower-order **components** as **deterministic**". This reminds of J.von NEUMANN's reliable systems made from unreliable **components**.

At the time SUTHERLAND offered his definition (1973), research on **chaos** had just made a start. It is now becoming clear that **micro-level** relative **indeterminacy** is the result of the multiplicity of independent local causes within the system. This is the background reason why, as stated by the same author (in relation to **human systems**): "... when systems under treatment begin to depart from the most simple kind of **mechanisms**, both our **mathematics** and our logic (even coupled with a large computer) fail to be able to manage the **interactions** and componential permutations of **behavior** potentially available" (p.45).

1977

MACRON^{1) - 2)}

"A multiple globally stable **regime**" (E. JANTSCH, 1976, p.72).

E. JANTSCH assimilates macrons to **dissipative structures**. According to R. ABRAHAM, such **BÉNARD phenomena** are macrons. A **complex system** may transit through different macrons, during macrodynamic **processes**, as explained by R. ABRAHAM (1976, p.134 - 148).

These transitions are "**catastrophic**" in THOM's sense.

ABRAHAM distinguishes (mainly for practical purposes) three basic types of macrons: physical, chemical and electrical. Biological systems present combinations of these three types, which constitutes the bases for **morphogenesis**. He states that "... the mathematical description of a macron is an **attractor**" and "It is actually the theory of **transitions of attractors**, or **catastrophes**, as developed by René THOM (1973), which is the basis for the geometry of macrons..." (p.140).

The subject is related to W. d'ARCY THOMPSON famous work "On Growth and Form" (1916), to C. LAVILLE's study of the "Mécanismes biologiques de l'atome à l'être vivant" (1950 - A quite unknown masterwork on **helixes** and energetic **whirls**' role in **morphogenesis**) and to A. TURING's research on "A chemical basis for biological **morphogenesis**" (1952), itself related to the BRAVAIS brothers work on phyllotaxis (1837).

The - supposedly - static "**objects**" we do observe at our temporal **scale** of **observation** are, in fact, a snapshot of macrons. A good example are apparently immutable geographic features: oceans, mountain ridges, etc.

1978

MACROSCOPE³⁾

"A symbolic tool, made of a set of **methods** and techniques taken from very different disciplines... to give a new (global) look into nature, society and man" (1975, p.10).

J.de ROSNAY states that the macroscope is not to be used to see farther away, or to blow up, but to observe that which is at the same time too big, too slow and too complex for our direct **perception**. As an example he gives human society "that gigantic **organism** totally invisible to us".

He adds: "In relation to society, we are today these particles and we must focus our attention on these systems which include us in order to understand them better, if they are not to destroy us. **Roles** are reversed: it is no more the biologist who observes the living **cell** with a microscope; it is the **cell** itself which, through the **macroscope** examines the **organism** which contains it" (p.11).

Of course, as noted by H.T. ODUM, the macroscope is **systems science**, used for "acquiring ways to discern the broad future and **mechanisms** of a system of **parts**" (1971, p.10). ODUM proposes the following way for the practical use of the so-called macroscope:

- "1. Survey, identify, classify
2. (Use a) detail eliminator. Prepare a **network** diagram of **compartments**
3. Determine **flows**
4. Simulate by a simplified **circuit model**
5. Experiment and manage (through a) demonstrator of overall **function** principles
6. Manage with **actions**" (Ibid.).

We should add: "Observe results" and, "Recycle the whole **process** all over again, and again.

1979

MACROSCOPIC and MICROSCOPIC^{1) - 2) - 4)}

There is a basically thermodynamic relation between the statistical microscopic **level** and the **deterministic** macroscopic **level** of **behavior** of a system. (I. PRIGOGINE, 1978, 1/1).

Macroscopic **determinism** expresses the global coherence **constraints** surging from, and imposed to the microscopic **behavior** resulting from **interactions**. This is for example what happens when a gas is enclosed within a container: molecular stochastic movement is translated at the macroscopic **level** as global conditions of temperature, volume and pressure.

This correspondence between microscopic and macroscopic **behavior** also seems to be the hidden condition of Adam SMITH supposed "invisible hand" in economic **processes** or generally, of the **emergence** of great conceptual or ideological currents.

1980

MACROSTATE^{1) - 3)}

"An equivalence **class** of microstates, determined by the equivalence relation "is **microscopically indistinguishable**" (F. HEYLIGHEN, 1990b, p.489).

HEYLIGHEN states: "To really distinguish microstates belonging to the same equivalence **class**, we would need to determine additional **variables**. Those **variables**, however, are "hidden" for the macroscopic **observer**" (ibid.).

This **concept** is closely related to the one of **level**, which is the **observation** setting where the corresponding equivalence **classes** do appear. And, of course, "**macroscopic**" is a relative notion.

1981

MAGIC BULLET ¹⁾

"Some invention that, when widely distributed, will make a **problem** disappear without leaving more **problems** in its wake" (S. FULLER, 1995, p.53).

FULLER asks: "Why do scientists fall so easily into the trap of thinking in terms of magic bullets shooting at magic targets?" In his opinion the main reason is that "scientists are consistently taught to think about science as quite different – and perhaps even independent – from the rest of society" (ibid)... not to speak of the **environment** in general.

Tinkering merely with a proximal cause, or even only with some immediate **effect**, is a result of the nonsystemic ivory tower style of work, proper of many specialists, combined with the cultural conviction that "Science" is all-powerful.

1982

MAGICAL NUMBER SEVEN ^{2) - 3)}

The maximum number of features that can be perceived in a discriminated way.

Actually, G.A. MILLER, who introduced the notion, is somewhat more tolerant about it and writes about "The magical number seven, plus or minus two", as defining "some **limits** on our capacity for **processing information**" (1956, p.81-97).

Basing himself on numerous experiments, MILLER came to the following conclusions:

"... the **span** of absolute judgment and the **span** of immediate **memory** impose severe limitations on the amount of **information** that we are able to receive, **process**, and remember.

"... the **process** of recoding is a very important one in human psychology (and)... in particular... linguistic recoding... that seems to me to be the very lifeblood of the thought **process**.

"... the **concepts** and measures provided by the **theory of information** provide a quantitative way of getting at some of these questions. The theory provides us with a yardstick for calibrating our **stimulus** materials and for measuring the **performance** of our subjects" (p.79-80).

MILLER's views are significant for various systemic concepts and **models**:

- our capacity to discriminate our **perceptions** are severely limited and we are easily exposed to **information overload**.
- it may be more useful in some cases at least to train ourselves in the **perception** of complex compounded **stimuli** units, possibly synthesized through various **levels** (for instance micro-, macro- and mega-, or **hierarchical** as in H. SIMON's "**Hora and Tempus parable**").
- the *well organized perception of patterns of correlations* and the construction of **gestalts** should be very useful.

1983

MAGNITUDE ⁵⁾

In **Systems Dynamics**, the quantification of some **elements** ("levels") in the system.

In **Systems Dynamics**, the quantities of stored **elements**, or registered orders, or members in **populations**, for instance, are magnitudes.

This meaning of the term should not be confused with the mathematical or the astronomical one.

1984

MAINTENANCE CONDITIONS of a SYSTEM ¹⁾

According to L.von BERTALANFFY, the maintenance of a system "involves continuous **change** of the systems of next lower order (*level*): Of chemical compounds in the **cell**, of cells in multicellular **organisms**, of individuals in super-individual life units. It was said, in this sense ... that every organic system is essentially a hierarchical **order of processes** standing in **dynamic equilibrium** ... We may consider, therefore, organic **forms** as the expression of a **pattern of processes** of an ordered system of forces. This point of view can be called *dynamic morphology*" (1969, p.81).

Generally the system maintains itself "not because of the absence of degradative **reactions** but because the synthetic and degradative **reactions** are proceeding at equal **rates**" (ibid).

1985

MAINTENANCE ENERGY DEMAND ¹⁾

Any system needs **energy** to maintain its internal **organization**. This demand of **energy** is greater in proportion to the **level of organization** of the system, which is in accordance with the **thermodynamics of dynamic equilibrium systems**, as established by I. PRIGOGINE.

This has to see with the system's **self-reproduction**: **Errors** must be repaired and this **process** includes a **cost**, which in last resort is always an **energy** one. Even the plan to avoid **errors** has its own **cost**.

Strangely enough, economy is one discipline where this concept is nearly completely forgotten: repairs are generally accounted for as an increase of general product, and, at the national **level**, there exists no patrimonial accounting of natural **resources**, whose natural replacement **cost** – when replacement is possible is not taken into account (Save in New Zealand, which recently introduced such accounting).

1986

MALTHUS "LAW" ¹⁾²⁾⁴⁾

According to Thomas MALTHUS, British economist (1766-1834), any **population** tends to grow limitlessly – and sometimes in an exponential way – until it reaches the upper **limit** of the available **resources**, mainly food. This may lead to catastrophic **population** crashes.

This is not really a "law", as frequently stated. In the case of human **populations** it has never been rigorously established and is widely doubted and criticized. It implies various hidden **assumptions**.

First, it could be true only for a system living in an isolated **environment**, i.e. for a **population** unable to colonize new territories. This could or course become the case for the human population in global terms on this planet.

Secondly, and again in the case of human populations, it does not take in account technical **progress**, which repeatedly allowed for new and better use of existing **resources**.

Thirdly, it is not evident that human population should necessarily grow forever. Leaving apart the possibility of massive **pandemics** (which could be considered a natural "malthusian" **mechanism**), the most recent **trends** in human **population growth** seem to indicate that there is a natural **regulation mechanism** at work: Human population explosions could be a transitional **phenomenon**, as in more and more countries, birth **rate** seems to decline, as well as death **rate**, in relation to material **development**.

In short, the final **validity** of the Malthusian **model** has not, until now, be either proved or disproved for the global human population on a planet whose **resources** are anyhow limited. It could be considered a caveat.

1987

MAN AS A PREDATOR ¹⁾⁴⁾

Man is obviously and by far the most accomplished predator in this planet.

He lives off the animal and the vegetal world on a massive **scale**, as no past or present other species has ever done.

He has become a planetary **parasite**, much more than a **commensal** or **symbiont**, and the most important and global accelerator of **entropy** in the whole **ecosphere**.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

He is also living off the geological spare-boxes of fossil **energies** and raw materials, sending enormous quantities of **waste** into planetary **sinks** that are becoming less and less able to cope with such a massive and in many case un-recyclable **flow**.

In fact, he is using the planet as a gigantic **commons** in the meaning of Garrett HARDIN (1968) and not giving any sufficient heed to the disquieting **signs** of the negative consequences of his ways.

It is quite probable that the global survival of the **man-planet system** will become the main problem during the 21st century.

→ **Predatory behavior**

1988

MANAGEMENT ⁴⁾

The direction and administration of an **organization**, estate or business.

The concept, in spite of an enormous quantity of publications of widely different scope and kind, remains quite fuzzy.

Various viewpoints appeared since the mid-19th Century, when management was practiced in a intuitive and generally authoritarian fashion.

So-called scientific management appeared next, with FAYOL and TAYLOR, whose views largely reflected the **deterministic** and **mechanicist** orientation of 1880-1930, with a dominant interest in quantitative **efficiency** and **maximization** of operative results.

Later on, economic and social influences seeped into management theories, according to the growing influence of working classes and the problems spawned by the big depression of the thirties.

The present situation seems to herald new and very deep conceptual **changes**, originating mainly in the growing **instabilities** resulting from accelerated technical **change** (including globalization by computers and telecommunications); differential **evolution** in different economic zones; **population explosion** (and, within few decades, universal **ageing**); and most recently the growing ecological problems.

The first result has been an explosion of partial solutions promoted by the so-called "gurus", most of them addressing **symptoms** more than **causes** and, in some cases, proposing "ways to do right the wrong things" (R.L. ACKOFF, 1995, p.43-6). In management, we are obviously suffering of overspecialized myopia.

It could not be said that systemics has completely resolved this issue. However, the global approach is powerfully present in P.B. CHECKLAND's **Soft Systems Methodology**; in J. WARFIELD's **Interactive Management** (and complementary **Global Design Technique**); in B. BANATHY's **Co-participative Design**; M.

JACKSON's **Total Systems Intervention** and in J.A. JOHANNESSEN's **Heterarchic-holographic model**... to name only some very significant proposals.

Management cannot anymore be stripped of its more general human and ecological dimensions and becomes a most important and all-embracing issue in systemics.

1989

MANAGEMENT and SYSTEMS MORALITY ¹⁾⁴⁾

J.van GIGCH tackled this subject in his book on "Applied General Systems Theory" (1978, p. 145-170). His views have been much influenced by C.W. CHURCHMAN's ones.

van Gigch writes: "In the past, science and **design** could remain value free... the optimum dictated solely by the "technological imperative" by which efficiency meant to find the **solution** with the lowest technical **costs**" (p.145)

However now "technological **efficiency** becomes subordinated to social efficiency". This implies that "to determinate the morality of a system's design is to evaluate the **effects** of the planner's intervention on those for whom the plan is intended. It involves a consideration of :

- 1- value measures-costs and utility
- 2- a science of values
- 3- the **ethics** of **spillover** effects
- 4- the ethics of causing **changes**
- 5- the ethics of **goals**
- 6- the manager's ethics
- 7- social **responsability**
- 8- the conservation ethics
- 9- consumerism and consumer protection
- 10- safety and product liability "

These points are extensively developed by van Gigch in his book. It is generally very important to understand that many of the terms used as for example: costs, utility, values, goals- have very variable psychological overtones (or "undertones"?) according to the different people who use them: managers, shareholders, **stakeholders**, outside **observers**.

The very signification of the concepts of morality and value needs to be deeply scrutinized.

→ **Clanthink; Decision making; Ethics and morality; Rights and responsibilities; Trade off decision**

1990

MANAGEMENT CYBERNETICS ²⁾

A cybernetic insight and **methodology** of management" particularly dominated by the **machine analogy**" (M.C. JACKSON, 1992, p.103).

JACKSON explains: "The starting point for the management cybernetic **model** of the or-

ganization is the **input-transformation-output schema**. This is used to describe the basic operational activities of the enterprise. The **goal** or **purpose** of the enterprise is, in management cybernetics, invariably determined outside the system (as with a first-order **feedback** arrangement). Then, if the **operations** are to succeed in bringing about the **goal**, they must, because of inevitable **disturbances**, be **regulated** in some way. This **regulation** is effected by management. Management cybernetics attempts to equip managers with a number of tools that should enable them to **regulate operations**. Chief among these are the **black box** technique and the use of **feedback** to induce **self-regulation** into **organizations**. The latter is often supplemented by **strategic control**, based on **feedforward information**, and external **control**. Management cybernetics makes little use of the more complex, **observer-dependent** notion of **variety**" (Ibid).

This is the point. Management cybernetics is basically a product of the so-called **1st cybernetics**, still basically **mechanistic** in its outlook. As observed by JACKSON such **models** "clearly lend themselves to autocratic usage by those who possess power".

However, this type of management should not be confused with S. BEER **Viable System Model**, much more inspired by von FOERSTER's et al **Cybernetics of 2nd order**, the "cybernetics of **observing systems**".

1991

MANAGEMENT (Hierarchic vs. heterarchic) ⁴⁾

G. DYER proposes the following differences between these two types of management:

"Hierarchic"	"Heterarchic"
Position-centred	Person-centred
Repetition oriented	Creativity oriented
Efficiency seeking	Innovation and efficiency seeking
Rules oriented	Results oriented
Rewards adherence to rules	Rewards outcomes
Information tightly channeled through formal structure	Maximize communication flow
Internally focused	Externally focused: alliances and coalitions
Uniformity	Diversity
Perception of a work-force	Human resource management
Top down	Bottom up

DYER, whose choice is **heterarchic** management, writes: "Devolution, decentralization and delegation of responsibility and power has become essential. **Matrix** - rather than bureaucratic - **structures** are now seen as much more desirable. **Control** is much more open-loop with semi-autonomous and self-managing teams common-place. The **role** of the manager or leader is now to develop an inspiring vision, to manage by example rather than to exercise **control**" (1992, p.1192).

1992

MANAGEMENT (Human Systems) ⁴⁾

M. ZELNY has characterized Human Systems Management in the following terms:

"1) Human systems are to be *managed* rather than analyzed or designed. HMS is not systems analysis or *design*".

(Note: In recent years, a new **concept of co-participative design** has emerged, which escapes from the limits of authoritarian and prescriptive **design**);

"2) Management of human systems is a **process of catalytic reinforcement** of dynamic **organization** and bonding of individuals. HMS does not design a **hierarchy of control** and command;

"3) The **components** of human systems are *humans*. HMS is not **general systems theory** but a general theory of human **organizations**;

"4) The integral **complexity** of human systems can be lost through the **process** of mathematical simplification... HMS is not **operation research**, econometrics or applied mathematics;

"5) The **interactions** between individuals are not those of electronic circuitry, **communication channels**, or **feedback loop mechanisms**. HMS is not **cybernetics** or **information theory of communication**"

(Note: i.e. is not **mechanicist cybernetics** of the first order, but could be aided by von FOERSTER 2nd order cybernetics);

"6) The order of human **organizations** is maintained through their structural **adaptations** under the conditions of environmental **disequilibrium**. HMS is not the theory of general **equilibrium**;

"7) the **concepts** of **optimization** and optimal **control** are not meaningful in a general theory of human systems. Human aspirations and **goals** are dynamic, multiple and in continuous **conflict**. Such **conflict** is the very source of their **catalysis**. HSM is not optimal **control** theory or theory of **conflict** resolution;

"8) The **inquiry** into human systems is **trans-disciplinary** by definition. Human systems encompass the whole **hierarchy** of natural systems: physical, biological, social and spiritual. HMS is not **interdisciplinary** or **multidisciplinary**, it does not attempt to unify scientific disciplines, it transcends them" (1977, p.27).

All these ideas are consonant with, for instance, P. VENDRYES **concept** of **autonomy**, i.e. the capability of a system (biological, social) to establish its own behavioral laws, and with MATURANA and VARELA's **autopoiesis**.

1993

MANAGEMENT in systemic terms ^{1) - 4)}

R.L. ACKOFF ironically observed recently that "managers suffer from panacea **overload**" (1994, p.43-6).

He argues that popular management panaceas do not work, most of the time, because they are applied **anti-systemically**. His diagnosis is as follows: "These failures have two principal sources. First, they manipulate the **parts** of systems without regard to how their manipulations affect the **whole** through **interactions** of the **parts**. Second, they tend to do the wrong thing righter rather than the right things" (p.43).

ACKOFF proposes the following systemic **rules** for management of an **organization**:

"1. Allow any **part** to change itself in any way that does not affect the performance of any other **part**, or the **whole**, provided the **part** has the **resources** necessary to make the **change**.

"2. If the **change** a **part** wants to make affects one or more other **parts** and either improve or does not affect the performance of the **whole**, it is allowed to make the **change** if it obtains the agreement of the affected **parts**.

"3. If it does not obtain the agreement of the affected **parts** the issue can be taken for resolution to the lowest **level** of management at which the **parts** converge.

"4. If a **part** has the necessary agreement but does not have the necessary **resources** to implement the **change**, it must try to obtain the **resources** it requires from the lowest **level** of management that has the **resources** it requires.

"Adherence to these **rules** requires continuous **monitoring** - a function that can appropriately be assigned to the **organization's planning** unit. It should be noted that these **rules** also operationalize the meaning of "empowerment" (p.45).

All this is about maintaining the internal **coherence** of the **organization**. More must be said about its **interrelations** with its **environment**.

ACKOFF's principles do refer to the internal management of the **organization**. However, even if perfectly managed in function of the **goals** and needs of the **organization** and its members, the final result can be disastrous if the external global conditions of its **survival** are not permanently monitored and taken into account. Every member of the **organization** should be duly informed and made conscious of this very fundamental aspect and correspondingly act in a responsible way.

1994

MANAGEMENT (INTERACTIVE) ⁴⁾

"A system of management invented explicitly to apply to the management of **complexity**" (J. WARFIELD, pers. com.).

WARFIELD states: "It is intended to be applied intermittently in **organizations**, to enable

those **organizations** to cope with **issues** or **situations** whose scope is beyond that of the normal type of **problem** that **organizations** can readily solve.

"I.M. is related to the ..."Science of **Generic Design**" which provides a scientific basis for the practice of I.M." (Ibid).

The characteristic steps of I.M. are"

"- Definition of the **situation** or **issue**: including

- 1) Approach to **complex issue**;
- 2) Exploration, i.e. **learning** more about the complex **issue**, and
- 3) Definition of the complex **issue**
- 4) Creation of several alternative **designs** for resolving the **situation** or **issue**
- 5) **Choice** of the alternative to be implemented

This will be achieved through the following phases:

- "- The **Planning** phase
- "- The Interactive Workshop Phase
- "- The Follow-up Phase

("Iterative application of the three phases will frequently occur").

WARFIELD also states: "IM **roles** are defined for both the supplier of IM services and the client **organization**. The **roles** are designed to achieve specific **objectives**, and to provide a compatible "cast" for the IM "drama". All specified **roles** must be filled. **Role** specifications are intended to provide quality **control** to IM use" (1995c).

Among the most important techniques used WARFIELD cites: **Nominal Group Technique**, **Interpretive Structural Modeling**, **Field Development**, **Profile Development**, **Ideawriting**, **Delphi** and **Tradeoff Analysis**.

(For complete information see J.N. WARFIELD, 1989, 1990 and 1995a)

1995

MANDALA ¹⁾

An Oriental complex design inscribed in a circle and symbolizing the universe.

The mandala has been used by some systemists (as St. BEER) to represent complex **wholes** and generally symbolize totality and **complexity**.

1996

MANIFEST versus HIDDEN ¹⁾

A **distinction** to be made between visible **states** and/or **behavior** of a system and other ones, which are not so readily apparent.

Very frequently, **deciders** of all kinds find themselves trapped in too narrow views about the **situations** they must meet. One of the most common delusions is the supposedly independent character of some aspects of a **situation** or **parts** of a system, when **interactions** remain unknown and are believed inexistent.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Another one is the incapacity to imagine **changes** that would not be **determined**, or worse, determinable at will. As stated by J. FOURASTIÉ, ignorance of ignorance is worse than simple common ignorance. Or, in G.De ZEEUW's word, we must become aware of **in-visibility**.

Systemics and cybernetics contribute efficiently to this important issue through the use of concepts and **models** about **complexity** and **complex change**.

1997

MANIFOLD⁵⁾

"A **class** with sub-classes" (T. & W. MILLINGTON, 1971, p.139).

T.A. and W. MILLINGTON give the following example: "A plane is a two-dimensional manifold of points, because it is the **class** of all its points, and each is specified by two coordinates, (x,y)" (Ibid.).

This implies that any **element** of the manifold is permanently recognizable and distinguishable from any other.

1998

MANIFOLD (Invariant)^{2) - 5)}

"A surface containing the **phase space** of a dynamical system which has the property that orbits starting on the surface remain on the surface throughout the course of their dynamical **evolution**" (S. WIGGINS, 1988).

WIGGINS adds: "...the **set** of orbits which approach or recede from an invariant manifold M asymptotically in **time** under certain conditions are also invariant manifolds which are called the **stable** and **unstable** manifolds respectively, of M. **Knowledge** of the invariant manifolds of a dynamical system as well of the **interactions** of their respective **stable** and **unstable** manifolds is absolutely crucial in order to obtain a complete understanding of the global **dynamics**" (Ibid.).

While previous to and independent of the study of **chaos**, the subject has now become an indispensable tool for the modelization of **turbulence** and **chaos** in mathematical terms.

1999

MANIPULATION^{1) - 4)}

An **action** of a system on its **environment** aiming at changing it in a hopefully favorable way.

Manipulation power increased throughout **evolution** of **living systems**. One of the most important effects of **sociality** has been the collective multiplication (not merely addition) of manipulating power over the **environment**. This is readily manifest even in insect societies, and also in **co-evolutive phenomena**.

However, manipulation must remain compatible with the maintenance of **environmental fitness** and **survival** value of the system, if it is not to become counterproductive.

The results of **socio-technical** manipulation applied on any **environment** should thus be carefully considered and closely monitored.

2000

MAN-MACHINE SYSTEM

→ **System (Man-machine)**

2001

MAP (Mental)^{2) - 3)}

A mental **model** we **construct**, knowingly or not, of some **part** of the world.

Of course, physical maps, or **models**, or even a sculpture, are originally mental maps, translated within **artifacts**.

S. BEER describes a map as: "the **pattern** of something, represented with much attenuation of **variety**, but with its significant **elements** preserved" (1974, p.37).

Still, a map is a kind of **metaphor**. It corresponds however to a very general type of **processes** in **neural networks**, even in animals: We register, interpret and retain experiences that can be retrieved when needed, let us say for instance, finding our way back home. As expressed by M. BODEN: "The map is used to generate an indefinite number of very useful "coulds" and "cannots". She adds this very important observation: "A list of landmarks is less useful: like the parroting of the first seven square numbers, it does not generate any new notions" (1990, p.47).

This means that a good map must include **information** about **interrelations** and dynamic **interactions** similar to G. KLIR's **source system**.

On a higher level of **abstraction**: "Theoretical maps help scientists to seek, and find, things never glimpsed before... For example, MENDELEEV's periodic table suggested to 19th Century chemists that unknown **elements** did exist, corresponding to specific gaps in the table".

However "A new theoretical map may not be universally welcomed, because yet-unseen **spaces** can be hard to imagine" (p.48).

This explains at least in part the resistance to new **paradigms**, and specifically to the **systemic paradigm**.

2002

MAP TERRITORY RELATION^{2) - 3)}

A. KORZYBSKI's "map territory" **metaphor** is fundamental to the **understanding** of **homomorphisms** and **isomorphisms** in **General Systems Research**.

KORZYBSKI stated: "Two important characteristics of maps should be noticed. A map is *not* the territory it represents but, if correct, it has a *similar structure* to the territory, which accounts for its usefulness" (1933, p.58).

Thereafter, KORZYBSKI transfers this **understanding** to **languages**: "If we reflect upon our **languages**, we find that at best they must be considered *only as maps*. A word is *not* the **object** it represents; and **languages** exhibit also this peculiar **self-reflexiveness**, that we can analyse **languages** by linguistic means. This **self-reflexiveness** of **languages** introduces serious complexities, which can be solved only by the theory of **multiordinality**" (Ibid.).

That the word is not the **object** is made perfectly clear by G. BATESON's example: "The word 'cat' cannot scratch us" (1973, p.153) and also from the following humorous A.N. WHITEHEAD's comment, quoted by KORZYBSKI: "The appeal to a **class** to perform the services of a proper **entity** is exactly analogous to an appeal to an imaginary terrier to kill a real rat" (1933, p.247).

As to theory of **multiordinality**, it is quite close to RUSSELL's theory of **logical types**.

Confounding the "map" with the "territory" leads generally to dire consequences, as well as using an incorrectly structured "map", whether geographic, linguistic or conceptual. The subject has also been reworked by H.von FOERSTER through his **Cybernetics of 2d order** (1981).

2003

MAPPING²⁾

The **process** of coupling two **sets** in a one-one correspondence.

St. BEER gives the very simple example of creating such a one-one correspondence between the 26 letters of the alphabet and the numbers 1 to 26 (1968, p.107).

While purely abstract mapping may be **isomorphic**, when we try to model **concrete systems**, "... in practice the mapping will be **homomorphic** - able to preserve some **structure**, but committed to losing some **information**. Thus our account of nature is 'true', but defective, and our account of such characteristics of nature as causation and law will change with the linguistic mapping we choose" (p.121).

Any **model** we do construct of any **part** of our **universe** is in some sense a mapping, and necessarily a merely **homomorphic** one, and: "The **variety** of the image system obtained with a **homomorphic** mapping is, of course, smaller than the original one" (R. VALLÉE, 1993b, p.75). It is essential for our conceptual (and possibly even mental) sanity to understand this and consequently, to relativize our **knowledge**.

Mappings are useful for the exploration of the interconnections and eventual **transformations** of the **contents** of the **set** of the interrelated items.

2004

MAPPING (Functional) in networks ²⁾

M. CAUDILL comments: "A **neural network** learns the **mapping** base on a collection of examples of the **relationship**, rather than requiring the formal equation as a computer would (M. CAUDILL, 1994, p. 19).

2005

MARGINAL VALUE THEOREM

→ Foraging theory

2006

MARKER ²⁾

A non-ambiguous **sign**, used in a **model** to represent a specific **element**.

J.von NEUMANN states: "A marker which can appear in ten different forms suffices by itself to represent a decimal digit" (1958, p.6). Of course, such a marker is really a collection of ten markers.

In case of using **digital** markers (0, 1) if one wants to represent a decimal digit: "A group of three two-valued markers allows 8 combinations; this is inadequate. A group of four such markers allows 16 combinations: this is more than adequate. Hence, groups of at least four markers must be used per decimal digit" (Ibid).

A coherent collection of markers, when given stable and precise values, constitutes a base for a **code**. The dots and dashes Morse **code** was one of the first systems using combinations of digital markers.

2007

MARKOV CHAIN ²⁾

A sequence of neither purely **random**, nor purely **deterministic transitions** from one **state** to any other in a system.

Another interesting definition by K. KRIPPENDORFF: "The **behavior** of an **informationally closed** and **generative** system that is specified by **transition probabilities** between the system's **states**" (1986, p.47).

He adds: "The probabilities of a MARKOV chain are usually entered into a **transition matrix** indicating which **state** or **symbol** follows which other **state** or **symbol**. The order of a MARKOV chain corresponds to the number of **states** or **symbols** from which probabilities are defined to a successor. Ordinarily, MARKOV chains are **state determined**, or of the first order. Higher orders are **history determined**. An unequal **distribution** of **transition probabilities** is a mark of a MARKOV chain's **redundancy**, and a prerequisite of **predictability**" (Ibid)

→ ("Ergodicity").

I. PRIGOGINE and I. STENGERS state the three general characteristics of Markov chains: "Non-repetitivity, existence of long range **correlations** and spatial **symmetry** breaks" (1992, p.90).

Markov chains are "statistically reproductive" and correspond to **deterministic chaos** "intermediary between pure **randomness** and **redundant order**" (Ibid).

2008

MARKOV CHAIN ANALYSIS ²⁾

Markov chains can be used to produce **forecasts** in probabilistic terms, when a sufficient number of statistical **data** can be obtained about the **interrelations** between some **events**. This is done through the construction of a **Markovian matrix**, usable to detect statistical degrees of **correlations**.

The underlying assumption is that the observed **transition probabilities** reflect some lax, but general, **determinisms** binding some **events** to some others, according to variable circumstances.

2009

MARKOV SOURCE (mth order) ²⁾

"An **alphabet** of **events** in which the probability of occurrence of a given number of the **alphabet** is a **function** of the m preceding occurrences" (K. SAYRE, 1976, p.29)

This is the generalized case of the first-order MARKOV source, "one in which the identity of each successive **event** (each **output event**) is a probabilistic **function** of the **event** immediately preceding (a specific **input-event**)".

K. SAYRE adds: "The mutual convertibility of a single **alphabet information channel** (a cascade of **channels**) with its corresponding MARKOV source is guaranteed by the fact that both can be completely characterized by a conditional probability **matrix** of the same basic form" (p.29-30).

2010

MARKOVIAN MATRIX ²⁾

A matrix that represents all the possible **transitions** of a system from any **state** to any other one.

The Markovian matrix resumes the probabilities of transition from a **set** of **states** to another **set** of **states**.

2011

MARKOVIAN MATRIXES (Hierarchies of) ²⁾

Referring himself to Markovian chains and matrixes, J. Mc CRONE writes: "Exactly the same statistical methods could be used to drive a higher **level** of analysis" (1993, p.30).

In speech identification or **language** analysis for example: "Markov **modelling** (can) be used to calculate the probabilities not only of one frame (of sounds or letters) following another, but also of one word following another and so produce a **language model** that could work out whether a person had meant "two", "too" or "to" simply from the **context** of what had been said" (Ibid).

In other words, Markov chains or matrixes reflect the **constraints** within the system and could thus become an interesting tool for **re-constructability analysis**.

2012

MARKOVIAN PROCESS ²⁾

The sequence of **transitions** from **state** to **state** in a system.

In a Markovian process, such **transitions** are submitted to **transition probabilities** between different **states**. These probabilities can only be statistically established, since any **transition** toward some **state** depends only on the immediately preceding **state**.

However, after a great number of **transitions** the average values of the respective **transition probabilities** from any **state** to any other one tend to stabilize.

This is because systems of this type are made of numerous **elements** only more or less laxly controlled in the long run by **environmental** and/or internal conditions.

This type of **processes** was extensively described by W.R. ASHBY in his "Introduction to Cybernetics" (1956).

→ Transition (Rule-obeying)

2013

MARKOVIAN PROCESS (Order of a) ²⁾

J. WICKEN states: "In **communication theory**, **messages** are conceived as generated from **symbols sets** through stochastic **processes** know as MARKOV's chains, wherein the presence of one **symbol** might or might not affect the identity of the following **symbol**, according to the **grammar** of **transmission**. SHANNON (C. SHANNON & W. WEAVER, 1949) referred to this as the "residue of influence" of one **symbol** on another. The reach of this "residue of influence" defines the order of the Markov process. If the presence of one **symbol** has no influence on what comes next, one has identical conditional probabilities, $p(i/j)=p(j)$ for any assignment of it, and the Markov order of the process is zero. If it influences only the identity of the immediately following element or symbol, the order is one and so on.

"The Markov order of a sequence chain is in turn reflected in its **complexity** and **compressibility order**" (1989, p.141).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

This concept had already been applied in a very interesting way by W.R. ASHBY in his "*Introduction to Cybernetics*", specially when used to describe a system (as defined by the **matrix** of its **states transitions**) able to produce a great number of **trajectories** (1956, 9/4 to 9/10).

In another sense WICKEN consider that "the **information** of a paragraph is certainly not reducible to SHANNON's **complexity** of letters on a page... We can't *compute* the **information content** of a treatise any more than we can *compute* the **information** content of an **organism** by a SHANNON-**complexity** analysis of DNA sequences" (p.142).

2014

MARKOVIAN SYSTEM^{1) - 2)}

G. PASK states: "The probability that a Markovian system will occupy any of its **states** at $t+1$, depends only upon its **state** at t , and probabilistic **transformation** P made up of fixed **transition** probabilities P_{ij} " (1961, p.42).

Thus, its **behavior** is **random** only in some sense: It is impossible to predict with total certainty the next **states** of the system, but the **matrix** of the fixed probabilities of **transition** between the different **states** gives us three important **informations**:

- the number of possible **states** is finite, however enormous it may be. In other words, the system is more or less **constrained** in ASHBY's sense.
- As the **transition** probabilities are *fixed*, some **states** are more probable and frequent than other ones. **Transition probabilities** are **constraints**, but they merely restrict, but do not suppress **randomness**.
- When the possible **states** are numerous, most specific **transition** probabilities become very small and nearly equi-probable. This consequently reduces **predictability**.

In PASK's words: "...an **observer** could perfectly well appreciate much longer-term **dependencies**" (p.43). The observer "could", but generally does not because the Markovian system has no *precise* **memory** of its past, but merely a general statistical one, which does not permit any secure **prediction**.

A **population's behavior** is generally markovian, as can be seen in some examples given by ASHBY (1956).

If, as observed by ASHBY some specific **state** of the system has zero probabilities of **transition** unto any other **state**, the system becomes stuck in this **state**. Such a **situation**, most of the time overlooked, generally implies its destruction.

PASK states moreover: "A **distribution** $P_i(t)$ is the *state* of the *Markovian system* and a sequence of **distributions** is a *behavior* of the *Markovian system*, conditional upon the chosen initial **state**" (p.44).

Figure: see entry **MASK**

Mask and Activity Array.

From G. KLIR: 1969, p. 117

And still: "By **analogy** with a **state determined** system any Markovian system reaches statistical **equilibrium**" and "In **equilibrium**..., regarded as an **information** source, it has a measurable **variety**. For n **states**, the maximum **variety** is $\log_2 n$, the **variety** of the **reference frame**, without any statistical **constraints**" (p.45).

Another significant property of the Markovian system is that it has no "**memory**". In PASK's words: "**Memory** or the ability to *learn* is not a property of the system, but of the **relation** between the system and an **observer**" (p.46). Indeed, it is the **observer** who construct the statistical **matrix**, after repeated **observations**. Even so, more **observations** could lead to a still different matrix.

A Markovian system is **metastable**: within its global **stability**, it undergoes stochastic jumps from **state** to **state**.

Under some **constraints**, Markovian systems become **ergodic**. Conversely, as observed by PASK, some **ergodic systems** include a "trapping" **state**, thus named because the system must end up in this single **state** (p.123).

A very important comment of PASK is that: "A system which is Markovian when observed in n **states** may not be Markovian if the **observer** combines some of its **states** and inspect a less detailed image" (p.125).

Thus, the 'lumping' of **states** (intentional or not), may very well deeply modify our **understanding** of the system.

2015

MASK²⁾

"A fixed **set** of sampling **elements**" (G. KLIR, 1967, p.194).

The mask is a partialized screen through which we observe specified **states** of the system. It is a kind of **variety reductor**. According to KLIR, he borrowed the term from A. SVOBODA (1963, 1964).

The concept is related to KLIR's "**Behavior system**", which "is defined by a **time-invariant relation** among selected present, past or future **states** of the **variables** in the **experimental frame**" (1988, p. 151).

The mask operates as a conceptual and formal **selector**.

It is an important tool of KLIR's **systems inquiring method** and **reconstructability analysis**.

KLIR describes the mask as follows: "The **pattern** of samples which is referred to as the mask, specifies those past, present or future **states** of the **variables** which are required to be a **part** of each sample. As such, the mask represents an hypothetical **memory structure** of the system" (1975, p.155).

KLIR moreover explains: "The problem of processing a given **activity** is related to a chosen mask (the mask represents something like the width of our view of the system) and may be stated as follows: Find samples of **activity** for all possible **time** positions of the chosen mask on the **activity**; express the **relation** between sampling **variables**, given by the obtained **set** of samples of **activity**, in the form of a **Boolean** equation, and solve the equation" (1967 p.194).

(for formalized aspects of the **method** see quoted papers)

see figure above

As observed by M. NOWAKOWSKA: "The **observer's** first choice is to define operationally the **phenomenon** which he studies. This **choice** depends on the **goal** of research, and

even for the same **goal**, the **choice** need not be unique". And: "... for the same **goal**, two researchers are likely to choose different **variables**. Whether or not the selected **variables** "cover" the **phenomenon**, in the sense that they provide **information** sufficient to attain the **goal**, is usually impossible to determine a priori with full certainty" (1986, p.62).

On the other hand: "Often the mask becomes changed in the **process** of taking the **observations**, i.e. one may decide to take some additional **observations**, of new **variables**, or of the **variables** observed until a given **time**" (p.66).

In other words, the **choice** and use of masks is partly **heuristic** and partly experimental.

2016

MATERGON²⁾ – 3)

"**Mass-energy**, of wave-corpuscular aspects, developing in **space-time** as differentiated systems".

The Spanish systemist R. RODRIGUEZ DELGADO introduced this synthetic concept, which reflects the artificial character of our mental disjunctions (of perceptive origin) when we conceptually separate **mass**, **energy**, **space** and **time**.

RODRIGUEZ DELGADO states: "The matergon concept offers a way to reach an integrated idea of natural, conceptual and artificial systems, connecting the philosophical **abstractions** with scientific and humanistic **models**" (1991, p.5-6).

The neologism seems useful as a permanent reminder that our way of splitting our **knowledge** of the universe into **categories** is probably a simple (or complex!) mental **artefact**, even if it is unavoidable.

RODRIGUEZ DELGADO explains at large the various aspects of the proposed concept in his last work (1997, p.43-51).

2017

MATERIALISM (Emergent)²⁾ – 3) – 5)

A theory that explains the relations between brain and mental **states** by considering the latter as a part of emerging **states** of the **brain** which however do not exist within the cerebral cells, the synapses, the dendrites or any other neural **element** (after R. RODRIGUEZ DELGADO, 1993a, p.258).

Mental activity depends upon the existence and good working order of the cerebral cortex: without this specific cerebral activity – different from the vegetative **functions**, which are controlled by other **parts** of the **brain** – it cannot exist.

The Spanish neurologist J.M. RODRIGUEZ DELGADO lists as follows the essential conditions of mental activity:

"1. A corporeal **structure** endowed with a normal physiology, able to provide oxygen, nutrients and other **elements** of cellular **metabolism** and able to eliminate the **wastes**.

"2. Sensorial **receptors**, which are the exclusive entries for the **information inputs** from within or without the **organism**.

"3. A functioning **brain**, endowed with the **mechanisms** needed for reception, circulation and emission of **messages**.

"4. **Organs** able to receive and express the orders and **messages** of the **brain**" (1993, p.297-8).

According to J.M. RODRIGUEZ DELGADO, emergent materialism is the most flexible hypothesis and at the same time the most helpful one for research on mental **phenomena** in terms of usual scientific techniques.

2018

MATHEMATICAL SYSTEM²⁾ – 3)

"A **set** of **objects**, with associated **rule** or **rules** of combination" (R. CARMICHAEL, 1956, p.4).

CARMICHAEL, a mathematician without known relation with systemics wrote, in 1956: "... any **set** of mathematical **objects**, which admits either (one or more) **rules** of combination of **elements** or **relations** among **elements** may be said to form a mathematical system. Systems, as so defined, underlie nearly the whole of mathematical science" (Ibid).

During the last 40 years, numerous mathematical developments relative to complex multicausal, mostly **nonlinear** and dynamic **inter-relations** have been introduced, creating new possibilities to modelize inter- and intrasystemic **relations** and complementing the traditional **models**. (See **catastrophe**, **chaos**, **fractals**, **fuzzy sets**, **graphs**, **percolation**, etc...).

2019

MATHEMATICAL TRUTH³⁾

A. RAPOPORT observed: "... mathematical truth, being established only with reference to propositions assumed to be true, cannot be shown to be true in the sense of scientific truth, that is, observationally or experimentally verifiable truth. Bertrand RUSSELL was not joking when he said that in mathematics we never know what we are talking about nor whether what we are saying is true" (1967, p.15).

The same point was made by A. EINSTEIN when he wrote: "As far as the laws of mathematics refer to reality they are not certain, and as far as they are certain, they do not refer to reality".

All this anyhow, does not need to be taken too hard: We just should remember that **models** – of any kind – are merely reflexions in human **brains** of (and on) a reality about which we cannot ever dream to attain absolute truth.

R. VALLÉE makes the point as follows: "Mathematics applies to physics because the **objects** and their properties recognized by experimental science in the physical world are *selected*, through **relations** that can be reproduced, in order to imply a mathematical definition which is amenable to calculation. Physical laws are merely the synthesis of the reproducible **relations** used for the definition" (1983b, p.563).

In some sense, mathematics are thus like an **inquiry** about the ways we make **models** of reality. When we start to look at reality in a different way, as we do as systemists, we are in need of new mathematical **models**, which are indeed appearing apace since 1965, and offer new ways to study systems **structures** and complex **dynamics**. Some older **models** also acquire new **meanings** and uses as for example **graphs**, **matrixes** and **binary algebra**.

2020

MATHEMATICS³⁾

A general overview of its relation to systemics.

According to A. KORZYBSKI: "From the point of view of **general semantics**, mathematics, having **symbols** and propositions, must be considered a **language**. From the psychophysiological point of view, it must be treated as an **activity** of the human nervous system and as a form of the **behaviour** of the **organisms** called humans" (1933, p.250).

KORZYBSKI considered mathematics "...a limited linguistic scheme, which makes possible great precision and **coherence** – but at the expense of such extreme **abstraction** that its applicability has, in certain ways to be bounded" (D. BOHM and F. David PEAT – 1987, p.8).

The same point was made by B. RUSSELL, who admitted that mathematics offers the appearance of **truth** because it is not saying what it is talking about: a comment that was echoed by A. EINSTEIN (see above).

In the same vein, K. BOULDING wrote: "... mathematics in any of its applied fields is a wonderful servant but a very bad master: it is so good a servant that there is a tendency for it to become an unjust steward and usurp the master's place" (1970, p.115).

All this justifies G. WEINBERG's caveat: "A degenerative disease sporadically afflicting the **general systems movement** is *hypermathematisis*: the generation of grand, sweeping and *valid* mathematical theories – often called "**general systems theories**" – which are as sterile as a castrated mule... because they can be applied to *anything* and thus to nothing: but they are doubly sterile because they are undistinguishable – on a mathematical **level** – from productive theories" (1975, p.68).

Mathematics, as a **language**, must necessarily take forms in accordance:

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

1/ – With the neural **organization** of the **brain**, still quite imperfectly known.

2/ – With the nature of the problems of which that **brain** becomes aware, as mental part of an **observer**. This is the reason why **nonlinearity** observed in **complex systems** tends to generate new mathematical tools.

This explains why *new* mathematics emerges frequently in synchrony with a new awareness of some **class** of hitherto undiscovered **phenomena**.

2021

MATHEMATICS and nonlinear systems^{1) – 2) – 3)}

According to R. MAY: “The elegant body of mathematical theory pertaining to **linear systems** (**Fourier analysis**, orthogonal functions, and so on) and its successful application to many fundamentally **linear** problems in the physical sciences, tends to dominate even moderately advanced University courses in mathematics and theoretical physics. The mathematical intuition so developed ill equips the student to confront the bizarre **behavior** exhibited by the simplest of discrete **nonlinear systems**... Yet, such **nonlinear systems** are surely the rule, not the exception, outside the physical sciences” (1976, p.467).

The trend to use linear mathematics in social sciences, for instance, has been a stumbling block for the use of systems concepts by sociologists and explains some of their sharp criticism. In J. MARTINO's words in his review of BERLINSKI's “On Systems Analysis”: “There is no proof offered by the **systems analysts** that social and political systems are at all similar to **control systems**” (1979, p.18).

MAY advocates the study of 1st order **nonlinear** difference equations, as a starting point. Since 1976, when he published this paper, a considerable body of new mathematics of **nonlinearity** has been created.

It should be emphasized however that the first important work on **nonlinearity** was POINCARÉ's 1889 paper on the **three bodies problem** and that POINCARÉ himself introduced various **topological concepts** that led to **chaos theory**.

MATHEMATICS and Systemics³⁾

The mathematician Hermann WEYL wrote in 1928: “Occidental mathematics has in the past centuries broken away from the Greek view and followed a course which seems to have originated in India and which has been transmitted, with additions, to us by the Arabs: in it the concept of number appears as logically prior to the concepts of geometry. The result of this has been that we have applied this systematically developed number concept to all branches, ir-

respective of whether it is most appropriate for the particular application. But the present trend in mathematics is clearly in the direction of a return to the Greek standpoint...” (Quoted by W.H. HUGGINS – 1963, p.132).

This view proved to be prophetic.

W.H. HUGGINS observes that “traditional mathematics does not provide us with adequate denotations of the following kind of entities: **signals, patterns, operators** and, generally, scaled **sets** of physical observables *in space*” (p.133).

To the “science of magnitudes”, as A. BOGDANOV described mathematics (1980, p.46), a complementary science of static and dynamic **connexions** is now growing swiftly. It includes **graphs, groups, topology, sets** (common or fuzzy), **catastrophes, fractals, chaos, criticality**, and possibly more.

G. KLIR acknowledges this: “Mathematically derived **systems knowledge** is the subject of various mathematical systems theories, each applicable to some class of systems. It consists of theorems regarding issues such as controllability, **stability, state** equivalence, **information transmission, decomposition, homomorphism, self-organization, self-reproduction**, and many others” (1991, p.101).

From a systemic viewpoint, G. KLIR observes: “Mathematical theories are most frequently developed for assumptions that are interesting or convenient from the mathematical point of view. As a consequence, they produce **methods** that cover rather small and scattered parts of the whole spectrum of systems problems... Hence, the primacy of problems in **systems methodology** is in sharp contrast with the primacy of **methods** in applied mathematics” (1993, p.39).

As a result, only parts of classical mathematics are well adapted to systemics. However, various new developments of mathematics appeared during the 20th. century, independently or not from G.S.T. and **Cybernetics**, as well as some new theories, not purely mathematical, but with a strong mathematical basement, which are obviously useful for systems sciences and **methodology**.

In a sense, systemics adopts or even spawns a new type of *qualitative* mathematical theories.

Hereafter, a tentatively classified list of these theories.

1. Older mathematical and logical theories and concepts well adapted to systemics: (partly based on L.von BERTALANFFY's “Outline of a G.S.Theory”) (1962, p.134-165).

- Theory of **categories** (N. HARTMANN)
- Differential and integral calculus
- **Isomorphic** laws: the exponential law; the **logistic** law (VERHULST); the law of **allometric** growth (W. PARETO).
- Mathematical theory of **populations** (V. VOLTERRA – A. LOTKA)

- **Binary** logic (BOOLE)
 - Theory of **sets**
 - Theory of **graphs**
 - Theory of **nets**
 - Theory of **cyclical phenomena**
 - **Stability** theory (LIAPOUNOV)
 - 2. Mathematics of cybernetics
 - Theory of **communication** (C. SHANNON and W. WEAVER)
 - Theory of **feedback, oscillations** and **control** (N. WIENER)
 - Theory of **information** (C. SHANNON, L. BRILLOUIN, D. MACKAY and others)
 - 3. G.S. generated mathematics
 - Mathematical theory of systems (von BERTALANFFY)
 - **Systems dynamics** (J. FORRESTER)
 - Theory of **hierarchical multi-level systems** (M.D. MESAROVIC, D. MACKO & Y. TAKAHARA)
 - Arithmetic relators (groupe SYSTEMA France)
 - **Reconstructability theory** (G. KLIR)
 - 4. Independently created mathematical theories important for systemics
 - **Topology**
 - **Catastrophes** theory (R. THOM -E.C. ZEEMAN)
 - **Fuzzy sets** theory (L. ZADEH)
 - **Fractals** (B. MANDELBROT)
 - **Theory of games** (J.von NEUMANN)
 - Theory of **algorithms**
 - Theory of **recursivity** (G. SPENCER BROWN)
 - **Deterministic chaos** (LORENZ, SMALE, RUELLE, etc.)
 - 5. Systemic mathematical theories originated in some specific sciences
 - Theory of **dissipative structures** and **bifurcations** in **non-equilibrium systems** (I. PRIGOGINE)
 - **Synergetics** (H. HAKEN)
 - Theory of **hypercycles** (M. EIGEN & P. SCHUSTER)
- G. KLIR emphasizes “the current trend of generalizing mathematical theories...” and gives the following examples:
- “from quantitative theories to *qualitative theories*;
- from **functions** to *relations*;
 - from **graphs** to *hypergraphs*;
 - from ordinary geometry (Euclidean as well as non-Euclidean) to *fractal geometry*;
 - from ordinary **automata** to *dynamic cellular automata*;
 - from linear theories to *nonlinear theories*;
 - from regularities to singularities (*catastrophe theory*);
 - from precise analysis to *internal analysis*;
 - from classical measure theory to *fuzzy measure theory*;
 - from classical **set** theory and logic to *fuzzy set theory and logic*;
 - from regular **languages** to *developmental languages*;

- from intolerance to inconsistencies of all kinds to the *logic of inconsistencies*;
 - from simple **objective** criteria **optimization** to *multiple objective criteria optimization*" (1993, p.52-3).

6. Other models and formulations

- attractors of distinct types
- games of life (J. CONWAY)
 (in fact: cellular automata)
- Markov Chains and Matrixes
- Markovian systems
- Matrixes
- Networks
- Percolation
- Power laws
- Renormalization
- Scaling laws
 (these last three closely related)
- Solitons
- Tilings
 (In most cases, see corresponding article)

MATHEMATICS (Polysemy in)²⁾³⁾

In his book "Facts of Science", V.V. NALIMOV observes that polysemy has now also appeared in the **language** of mathematics (1981b, p. 75)⁴⁾. He writes that, from **Gödel's theorem** "it follows that human thinking is richer than its deductive formulation" (Ibid)

This new mathematical polysemy resulted (quite recently) of the use of mathematics "for describing poorly organized, diffuse systems... (as) the requirements placed on mathematical **descriptions** have become less strict. Whereas the description of real phenomena in mathematical language was earlier regarded as the expression of a **law** of nature, now it has become possible to speak of mathematical **models** which may all simultaneously be legitimate" (Ibid)

Nalimov adds, further on, that "this **polymorphism** of the language of applied mathematics increases its **flexibility**" (Ibid)

However he feels clearly some qualms about this evolution. He escapes more or less from these by defining mathematical models "as a question to Nature asked by a Researcher"

"Matters like **computer modelling** technique or **fuzzy algorithms**- of enormous practical usefulness are surely pertaining to this type of "questions asked". Are mathematics turning from **deductive** to **inductive**...and even possibly **abductive**?

2024

MATRIX²⁾

"A table of columns and rows employed for organizing a **set** of interrelated values."

A matrix is basically a combinatory device. It can be used, for instance, to discover all the possible **interconnections** between various characteristics; or indicate all the possible

transitions from one **state** or **phase** to others, indicating its various probabilities. It may also be constructed and operated as an **encoding-decoding** device.

J. WARFIELD and N.M. AYIKU proposed the use of a number of interconnected **binary** matrixes to understand complex **flows** of any kinds within a system. They emphasize the following types of matrixes:

Input matrix: to be used to define what **inputs** are required by each actor

Output matrix: to be used to find out what **outputs** are produced by each actor

Actor interaction matrix: to respond to the structural question: what actors supply **inputs** to what other actors

Input-Output matrix: responding to the structural question: What **inputs** are required to produce what **outputs**.

It may be useful to convert these matrixes into **graphs**, which may lead to an "**interpretive structural model**" (J. N. WARFIELD & N.M.B. AYIKU, 1989, p.29-35).

→ J. WARFIELD for a very complete survey of the subject of matrixes use in systemics (p.220-63).

Matrixes are generally two-dimensional, but may have more dimensions. This however makes their practical use much more difficult.

→ **Markovian matrix**

2025

MATRIX BUILDER^{2) - 3)}

A general **heuristic** tool to be used to discover significant **interconnections** in the whole systemic field.

This was a L. TRONCALE proposal during the fourth FUSCHL conversations (1985, p.73). Its present status is unfortunately uncertain.

According to TRONCALE: "This tool would aid a user in identifying key **parameters** of a problem using general **morphology**, then use these to build several axes which describe a multidimensional **space**. Each axis would represent a distinct and separate, but critically important approach to the problem under study. Comparison between the axes would create many multidimensional **intersect spaces**... Each... would contain **information** on how the various **categories** of the various **taxonomies** of **parameters** (represented by all axes) interact with each other. In this way, each particular of each **taxonomy** should be systematically compared with each particular of the other **categories** and **taxonomies**. Each **connection** specified in an intersect would be explained in **semantic** terms, linked to literature or **data**, and... would serve as a point of departure for **tracing** to other **connections**. This tool would combine features of **expert systems**, relational **data** bases, and some unique, new capabilities into a user-oriented tool".

In synthesis, the matrix builder could become a meta-**taxonomic** tool.

The present work may somehow be considered as a not-formalized and quite partial version in colloquial English of a matrix builder.

2026

MATRIXES and GRAPHS²⁾

S. LIPSCHUTZ writes: "It is sometimes practical, especially for computational reasons, to represent (a graph) G by a matrix. Note that the **edges** of G can be represented by an $n \times 2$ integer matrix B where each row of B denotes an **edge** of G... This *edge matrix* B does not completely describe G unless we are also given the number m of vertices (**nodes**) of G..." and: "...the adjacency matrix is very useful in deciding questions of **connectivity**" (1976, p.88).

Conversely, it may be useful to represent a matrix by a graph.

→ **Graphs**

2027

MATRIX (The)¹⁾³⁾⁴⁾

L.H. KAUFFMAN writes that this film "is a cinematic exercise in virtual reality and virtual logic" (1999, p. 65)

It could also be said that it is an animated **metaphor** of probably quite basic characteristics of human societies. Kauffman describes it as follows: The Matrix is all around you. It is in the air you breathe, in the ground you walk on, in the sights you see and in the feelings that you feel. You yourself are composed of it just as much as it is composed of you" (Ibid)...and of course, of all humans.

"You imagine yourself to be an **observer** independent of the Matrix, but the very possibility of your **observation**, your sense of **Self** and World is produced by the Matrix.

"One might say that the Matrix observes itself, but that would be overstepping the bounds of **language**, for the very act of saying that "it" observes "itself" presupposes a split between the observed and the observer that does not exist in the presence of the act" (Ibid)

Kauffman's short paper develops striking comments. In its own way, it is reminiscent of the "Public opinion" engraving of Arnold BÖCKLIN.

One may also ask oneself if the Matrix metaphor could be a significant step toward the deeper **understanding** of ourselves, that all humans need urgently if we are to avoid the global demise of the species.

→ **Contingency (Mutual); Cultures as systems; Language and culture; Metaphor; Parallel distributed processing; "Reality" (Riddle of); Stigmergy; Swarm intelligence**

2028

MATTER^{1) - 3)}

Anything that can be perceived as occupying some **space** during some **time**.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

The true nature of matter seems to become evermore elusive in modern science. EINSTEIN's understanding that particulate matter could be the result of local and instantaneous **energy** concentrations in a fundamentally continuous **field** is becoming more and more confirmed.

H. SABELLI and L. CARLSON-SABELLI formulate that idea as an hypothesis: "**Structures** of matter are formed when opposite forces in a system are both of high and similar intensity... At the most fundamental **level**, **energy** forms matter, which is an **equilibrium** or **symmetry** between opposing **energies**" (1992, p. 663).

D. BOHM and F.D. PEAT go farther and write: "Current quantum **field** theory implies that what appears to be empty **space** contains an immense "zero point **energy**", coming from all the quantum **fields** that are contained in this **space**. Matter is then a relatively small **wave** or **disturbance** on top of this "ocean" of **energy**" (1987, p.199).

As stated by A. KORZYBSKI, there can be no matter outside **space** and **time** and the equivalence and convertibility of **energy** into matter and conversely, also proposed by EINSTEIN, has been dramatically confirmed by nuclear fission.

The possibility that matter appears as the materialization of **vortexes** in interacting **fields** has also been studied by the French engineer Ch. LAVILLE (1950)... and obviously already sensed by d'ARCY W. THOMPSON in his famous work on "Growth and Form" (1916).

Matter is somehow related to **information**. L. CARLSON-SABELLI and H. SABELLI state: "**Energy**, matter and **structure** coexist as three distinct inseparable aspects of **action**. Even the simplest subatomic particles have material and energetic aspects (quantum wave, particle duality) and contain **information**, albeit limited (quantum **uncertainty**)" (Ibid).

To conclude, so-called "matter" could be a fragmented perceptive and conceptual interpretation of an integrated reality whose true nature remains elusive.

2029

MATTER-ENERGY STORAGE²

→ **Storage (Matter-energy)**

2030

MATTER-TIME¹⁾

The astrophysicist J.A. WHEELER, as quoted by H.C.von BAYER (2001, p. 16) wrote: "**Matter** tells space-time how to curve, and **space-time** tells matter how to move"

2031

MAXIMIZATION and ORGANIZATION^{1) - 4)}

The principle of global **energy flow** maximization proposed by LOTKA (see hereafter) implies a more or less hidden condition: the minimiza-

tion of **dissipation** rates in the participating systems, which constitute an interconnected **net of energy** using **organisms**.

The **optimum** then corresponds to a **situation** in which the global system maximizes the **energy flow**, but inversely minimizes its general **dissipation rate**. This corresponds to the maximum **variety** in the global system and to *efficiently optimal use of energy*.

Accordingly, R.N. ADAMS enounced the principle in quite a different way: "The distinctiveness and **stability** of the **boundaries** of a **dissipative process** vary directly with the tendency of that **process** to seek a minimum **dissipation rate** and inversely with its tendency to maximize **energy flux**" (1988, p.149).

ADAMS applies the principle to **social systems** and states some interesting points:

"The **dissipative process** sets its own energetic **boundaries**" and,

"Similarly, when the amount of **energy** available to a social assemblage is limited, the **dissipation** of that **energy** will lead to more rigid definition of the **boundaries** of the assemblage, to its evolving increasingly closed **self-organization**". Consequently: "Thus limiting **energy flow** is **self-organizing**. **Energetic boundaries** become clearly evident when efforts are made to conserve the **energy** available, because this requires reducing external **dissipation**" (Ibid).

The principle is clearly related to the construction of complex social **organization** in **ecosystems**, animal societies and **human systems** where the **heterogeneous variety** is put to the best use. Social **complexity** in turn, is an **emergent process**. This connects the whole subject to the **far away from equilibrium dissipation processes** considered by PRIGOGINE and his collaborators.

It opens very stimulating insights on the present **process** of planetary economic, social and political **integration**.

2032

MAXIMIZATION PRINCIPLE (LOTKA)^{1) - 4)}

"In every instance considered, natural selection will so operate as to increase the total **flux** through the system, so long as there is presented an unutilized residue of **matter** and available **energy**" (1922, p.148).

It is noteworthy that LOTKA himself seemingly never used the expression "Maximization Principle", which allows for dubious interpretations. (see below: "**Maximum power principle**").

In any **environment**, there is always room for a species able to utilize some free **energy**. The very important consequence – in particular for the human species – has been thus described by LOTKA, in 1924: "Such a species

will therefore, other things being equal, tend to grow in extent (numbers) and this **growth** will further increase the **flux** of **energy** through the system" (1956, p.357).

This is exactly what happened with our species, particularly since we learned to use fossil **energy**. Combined with **structuration through dissipation** as explained by PRIGOGINE, the Principle could be considered as the prime mover of all of human history.

In 1945, LOTKA added a caveat that nobody seriously heeded, even if it could very well be the key to the *future* history of mankind: "The principle contains a reservation: a maximum compatible with the **constraints**" (1945, p.192).

In an **environment** globally exploited, the decisive **constraint** could be the massive **accumulation** of non-recycled **waste**, particularly thermal **waste**.

We are unaware of **Gaia's constraints** or choose to ignore them. This could have portentous consequences.

2033

MAXIMIZATION vs. OPTIMIZATION¹⁾

In the **linear** perspective, optimization is frequently confused with maximization. This problem arises from the belief that some **function**, supposedly independent of **context** (the famous mental jingle "... *et ceteris paribus*") can be (and should be) maximized. However, in **complex systems**, which are always **nonlinear**, true optimization requires the best possible reciprocal harmonization of the different **functions** of the system, which can be obtained only through a repeated balancing act within the global **network**.

2034

MAXIMUM POWER PRINCIPLE²⁾

"Systems which use energy best, survive" (H. & E. ODUM, 1976, p.39).

As enounced under this form in 1976 by H. and E. ODUM, this principle is different from LOTKA's one and seems somewhat over-simplified.

LOTKA seems to refer himself to complex **ecosystems** (The "**world engine**" being the most global one), but not to separated individual species.

H. ODUM himself recognized in 1983 that: "According to LOTKA's maximum power principle, systems tend to develop **designs** that maximize power and thus may be expected to develop loadings less than efficient" (1983, p.116, quoted by R.N. ADAMS). This author observes: "There is nothing in LOTKA's principle that implies that systems "tend to develop ... maximum power". Indeed, LOTKA asserts that whether higher **energy**-using forms emerge is "determined by other principles" (ADAMS, 1988, p.38-39).

→ **Saint Matthew's Principle**

2035

MAXWELL's DEMON²⁾

An imaginary being endowed with sufficiently keen **perceptions** to be able to reverse **entropic disorder** in an **isolated system** by **controlling** in a **selective** way the movements of its **elements**.

Such a being would be capable by its action to violate the **second law of thermodynamics**.

However, as stated by A. RAPOPORT: "MAXWELL's argument... contains a basic fallacy. If the demon is placed inside the system, the **processes** going on within him must also be taken in account in computing the total **change** in **entropy**. It was subsequently shown by L. SZILARD (1929) and later by L. BRILLOUIN that the **processes** within the demon (whether he is a **mechanism** or an **organism**) must be such that the decrease in **entropy** effected by his intervention is at least compensated (in general, over-compensated) by an increase of **entropy** in the demon. If, on the other hand, the demon intervenes from outside the system, then the system can no longer be considered to be **isolated**, and the **Second Law** does not apply" (1966, p.7).

The point can also be made by observing that the demon must acquire **information** through an observational **process** that is not gratuitous in **energy** terms and, moreover, needs **energy** in order to move the **elements** in an ordering way.

2036

MEANING^{3) - 4)}

"The set of **functional** properties of the **response** produced by a **stimulus**" (after R.L. ACKOFF and F.E. EMERY, 1972, p.170).

These authors emphasize that "... a **sign** may have different meanings for different individuals, or different meanings for the same individual at different times" (Ibid)

Quoting C. CHERRY, they add: "A meaning is not a **label** tied around the neck of a spoken word or phrase. It is more like the beauty of a complexion, which lies altogether 'in the eyes of the beholder' (but changes with the light!)" (p.171).

J.Z. YOUNG expresses a similar opinion: "A **sign** has meaning when a **group** of people has adopted a particular **program** for using it. Hence the meaning of a word is defined by the **rules** for its use and the circumstances under which it can be verified" (1974, p.295). In short, meanings are, by necessity, **accepted** meanings (G. WEINBERG, 1975, p.56).

Meaning is a many-sided concern. Different views may be more complementary than opposed.

For K. SAYRE, meanings "... are neural **patterns** removed from exclusive **control** by external **objects**, and brought under the **control** of verbal **signals**" (1976, p.210).

While it remains to be better understood how verbal **signals** systems become organized by individual **brains** (**autogenesis of language**), this is a bridge between so-called "objective" and "subjective" concepts of meaning. From another viewpoint, **languages** become useful only when they are usable between individuals who have a **similar control** of verbal **signals**. There are thus at least two enmeshed **levels** in this **process**: the individual one and the collective one. However **similar control** is transmitted from generation to generation by training and teaching.

In E. SCHWARZ words, meaning is hetero-referential, emerging from **interrelations** (1992, p.757). It must be acquired by **learning**, **adaptation** and **accommodation** in individual minds, through a very complex cerebral **process**, still poorly understood. **Signals** carry meaning only for pre-structured minds, but minds become pre-structured by previous interpretation and absorption of formerly non-significant **signals**. Such a **process** would be impossible outside of complex social and cultural settings. We receive our interpretations from people who already possess them and, to acquire these significances, *we must accept them*. Only later on, may we in some cases revise and correct them.

We use these interpretations, acquired by **learning**, to observe the world around us, which implies that they constitute a **frame of constraints**, i.e. a **frame of reference**: Shortly, there is a **socio-cultural matrix** of accepted meanings.

Of course, as stated by D. Mac KAY: "Questions of meaning need not arise until we bring in the human links in the chain..."

"The original speaker, we suppose, means something by what he says. His utterance has meaning, at least for him. Yet, in the next stages of the chain... (the generation of sound waves and all the rest of it) all **signs** of his meaning seem to have disappeared... Yet, finally, when the **message** reaches the ear of a human listener, its "meaning" seems to pop up again from nowhere." (Mac KAY, 1969, p.20).

Such a **process** evokes awkward questions and still more so that the meaning does still not reappear into the ear, as the **input** must be processed by the **brain** in ways up to now poorly understood.

Another curious aspect is that, without an appropriate **receiver**, any meaning is lost. In Mac KAY words: "Meaning is always meaning *to someone*" (1969, p.36).

When the **message** reaches a **receiver** apt to give it a meaning, this acts like a selective **function** and may trigger a specific **behavior**.

As observed by P.Y. RACCAH, meaning can be considered as a set of instructions to the **receiver**, or imply **constraints** needed in order to make some sense out of the **message** transmitted (1993, p.1247).

2037

MEANING AND INFORMATION³⁾

J. S. WICKEN states: A "reader" brings implicit information to read which is read as part of the system information in which he/she participates- whether this be a theory or a poem. We don't know how to quantify this dimension of information. An **organism**, in an important sense, results from the **grammar** of its own generation: we don't know that **grammar** yet. Although we can understand **order** and **complexity** in crisp mathematical terms, "meaning" requires a transaction between knower and known whose terms are presently remote from our **understanding**" (1979, p.142).

What the "reader" introduces in the **process** of meaning formation depend on her/his cultural location, historically as well as geographically and his/her specialization. Moreover, everyone brings in his/her own "mindscape" (see MARUYAMA, 1966).

Meaning is mainly subservient to implicit **knowledge**, i.e. formerly acquired and organized information.

2038

MEANING (Imaginary)³⁾

A meaning does not necessarily reflects some (so-called) "**objective**" reality.

I. SEMETSKY observes that, for Ch. S. PEIRCE, the american founder of semiotics: "The **object** to which the **sign** refers may not have a solely physical existence but may as well be a thought, a dream, or an imaginary entity" (2001, p. 112)

A good example is the red cross. This sign was created by inverting the colors of the swiss flag and was then given a meaning: "medical help available". This meaning was progressively transmitted and accepted by more and more people.

It thus acquired the status of significant **symbol** and is now universally known.

But the meaning it conveys could as well have been represented by a green star with five spikes or by two intersecting circles (one red and one blue), or by a stylized heart, or any other easy to read.

This shows that any sign is a sign only through

- a) a psychic invention of an individual creator
- b) **conversational communication** among various individuals
- c) by **transmission** in the time dimension to new bearers

→ **Ideograms; Language (visual)**

2039

MEANING (Meaning of)³⁾

D. Mac KAY states: "A distinction should be carefully made between the notion of meaning to the **receiver**... and the notion of intended meaning (*by the transmitter*) and generally accepted meaning." (1969, p.72).

- Intended meaning is the meaning which the **transmitter** tries to convey to the **receiver** or receivers. It depends on the **level** and soundness of **knowledge** and intentions of the **transmitter**.
- Generally accepted meaning is that which is accepted by **consensus** by a majority of the concerned people (irrespective from its intrinsic factual **truth** or falsity, while it is generally presented as "**truth**").
- Meaning to the receiver is what the **receiver** understand from the **message** received as it evokes in him a complex **background** of former **reactions** and **knowledge**.

The **receivers** views may or not coincide 1) with the **transmitters** interpretation; 2) with the common **consensus** and the generally admitted "**truth**".

2040

MEANING OF A MESSAGE³⁾

"Its selective function on the **range** of the recipient's states of conditional readiness for **goal-directed activity**" (D. Mac KAY, 1969, p.24).

By "conditional readiness" Mac KAY understand the number of possible **states** of the **subject**, some of which may or may not be actualized by the message. He writes: "It is not until we consider the **range** of other **states**, that *might have been selected but were'nt*, that the notion of meaning comes into its own. A **change** in meaning (*in the message*) implies a different selection from the **range** of **states** of readiness" (Ibid).

In other words, the message is an activator of **behavior**, but then only within the **limits** of the possible **states** of the **subject**.

The concept is akin to:

1. VENDRYES' concepts of **autonomy** and subjective probability
2. MATURANA and VARELA's concept of **auto-poiesis**

It does not however clarify the mechanism of the acquisition of the "**range** of the recipient's (*possible*) **states** of conditional readiness".

In any case, Mac KAY concludes "... meaning is clearly a **relationship** between message and recipient rather than a unique property of the message alone" (Ibid.).

This is why the same message may very well convey different and even opposed meanings for different recipients.

2041

MEANING ORGANIZER¹⁾²⁾

The pedagogical use of some very general term or **concept** in order to create **correlations** among a number of different themes.

R. NUMMELA CAINE and M. CAINE give as an example the concept of "Family", used as a **mental frame**, or thematic **map**, to interrelate many quite different types of groupings: Families of humans (in psycho-sociology and anthropology); families of laws, or families of **elements** (in physics); animal or vegetal families (in natural sciences **taxonomies**); families of rulers, family trees (in history); families of planets or stars (in astronomy and astrophysics); etc... (1994, p.129).

Of course, such meaning organizers may not even reach the **analogies** or **metaphors levels** and should be used with care. They are not much more than mental catalyzers, useful to construct **mental maps**.

2042

MEANING SYSTEM^{3) - 4)}

The set of **values**, **norms**, **concepts**, **rules** and **models** proper to some **human group**.

F. ROBB states: "In the initial stages of the 'life' or an institution, intensive **conversation** plays a major role. This defines the kernel of the system of meanings and legitimates in the participants' **understanding** the taken-for-granted assumptions upon which the meaning system rests" (1993, p.2).

The meaning system stabilizes the **organization** or institution, because it gives it **cohesion**, avoids deviant **behavior**, spares efforts and **time**, limits the squandering of **resources** and, generally speaking, **regulates** the whole **activity** of the system.

In a much extended and **metaphoric** sense the genetic **code** could possibly be considered as the cellular meaning system. It would be very interesting to see if it is elaborated through some kind of cellular "**conversation**". And, of course, meaning systems are constructed in each individual **brain**: could it be through some kind of neural "**conversation**" about **percepts** (obtained from **conversation** with other people about **objects** and **concepts**?).

2043

MEANING THEORY¹⁾²⁾³⁾⁴⁾

K. BAUSCH resumes as follows J. HABERMAS views on meaning. "...it is based upon the **semiotic model** of a linguistic **sign** used by a speaker (sender) with the aim of coming to an **understanding** with a hearer (receiver) about **objects** and state of affairs. In such a semiotic model of communicative **actions**, meaning has three elements: the cognitive **representation** of a state of affairs; the expression of the expe-

riences of the speaker; and the direction of requests to addressees" (Glossary, pers. comm., 2002)

In fact, many other aspects are also critical for the construction and the **transmission** of meaning (see cross references hereafter)

→ **Brain**; **Code**; **Code creation**; **Cognition**; **Communication (Human)**; **Communication theory**; **Concept**; **Conversation**; **Frames of references**; **Information**; **Log-on**; **Meaning**; **Metron**; **Observer**; **Organization closure**; **Redundancy**; **Semantics**; **Semiotics**

2044

MEANINGLESSNESS³⁾

Character of a **message** which "lacks a selective **function**" (D. Mac KAY, 1969, p.25).

D. Mac KAY states: "We have to distinguish between meaninglessness due to:

- a) lack of definition of selective **functions** (e.g. non-sense syllables, or words, or sentences)
- b) absence of the appropriate **range** in recipient (e.g., colour to a blind man)
- c) incompatibility of two or more **components** of the selective **operator** (e.g., the milk is isocoles).

"Clearly, utterances can be partially meaningful (or meaningless) under the above heads" (p.129).

More specifically, the following example in **languages semantics** make these aspect clear:

a) "Amünkoni felpertna potarisko hapu" is a fancyful sentence without any meaning in any **language**. But the **receiver** can be reasonably sure of this only if I, as the **emissor**, tell him so and *if he supposes that he may believe me*. Curiously the above fancyful sentence could become a meaningful example of meaninglessness, i. e. acquire meaning.

b) "Mutoto alivunja sahani moyo" is a correct sentence with a precise meaning in Kiswahili (an East African language). It is meaningful for somebody who knows the **language** and meaningless for one who does not. This latter one is unable to perceive the difference between the imaginary and the genuine significant sentence.

c) "The milk is isocoles" is nonsense for both **emissor** and **receiver**, provided both do know English. However someone who does not, is unable to differentiate this sentence (senseless for him/her) from any other senseless utterance of types a) or b).

One could possibly add still a fourth case, when an old **language** is lost and is meaningless because there are no more **emissors** or **receivers** who are able to make sense of it.

2045

MEANINGS (Formation of)³⁾ - 4)

According to F. ROBB: "... commonly agreed meanings are formed, by negotiation or compulsion, between at least two conversants. The formation of meanings, in this context, is taken to include making **distinctions** between **objects** in experience (or in thought) and their ground, forming mental **models** and making valuations about **situations** and **objects**; so that 'good' is discriminated from 'bad', 'desirable' from 'undesirable', and 'true' from 'false'".

Moreover, "**Conversations** may also negotiate what constitute valid ways of making these **distinctions** and of establishing these values" (1993, p.1).

I. BEESON (1997), after considering HUSSELER's **phenomenology** and its critique by DERRIDA (1973), and MERLEAU-PONTY's **Phenomenology of perception** (1962) observes: "Our existence is shown as fundamentally intersubjective, but not as fundamentally rational. Meaning is nowhere constant or fixed, but in achieved by people working together to make sense of a world whose **boundaries** are constantly reforming. Such work always throws up meanings not prefigured by existing **understandings**". In short "**Rationality** is revealed as a superstructure"...and "...a rhetorical rather than a logical achievement"

Such a relativity looks suspectedly like quicksands and could easily lead to rational paralysis. It is however for sure necessary to remain careful about so-called meanings.

→ **Falsifiability; Filter; Ontological skepticism; Perception (Limits to)**

2046

MEANS-ENDS ANALYSIS²⁾

A **systems analysis** technique used to determine which **inputs** are necessary to obtain some pre-defined **outputs**.

W. LEONTIEFF's **input-output matrixes**, for instance, are tools for means-ends analysis. Of course, means-ends analysis is just that: it does not show whether it is useful or sensible to use such **inputs** in order to obtain such **outputs**. It does not give for example, any **information** about any kind of possible **side-effects**, as for instance unexpected **environmental** or social nocive outcomes, or financial problems.

2047

MEASUREMENT¹⁾ - 2)

1. "Any explicit move to obtain some quantitative **knowledge** of a system, or part or **process** of a system" (J.L. DESTOUCHES, 1990, p.479).
2. "The assignment of numerals (and numbers) to represent properties" (N.R. CAMPBELL, 1957, p.267).

(According to CAMPBELL, a numeral is a material or quasi-material **symbol**, while a number is a mathematical concept. While numbers can be added or multiplied, numerals cannot be).

Measurements can be obtained using some instrument or device, but also by organizing a statistical **inquiry** or even using a more approximate way of evaluation.

J.L. DESTOUCHES states: "Any measurement is imprecise. It implies the **interaction** during a certain **time** of the studied system and another specific one, the measurement device (endowed with some observable characteristic, which will have changed after the measurement). Thus, any measurement implies a whole **process** with complex **transmission** devices of the obtained **information** and for showing the results. This introduces limitations to the **knowledge** of the system. One may conceive that some measurements cannot be made simultaneously because both measurement instruments cannot be used at the same moment, as it is for example, the case in quantical physics".

"While any positive **knowledge** about a system must be obtained by measurement, any measurement presuppose a theoretical **concept**, or at least a **model**. This is a dialectical situation. The **model** includes constants, **parameters**, **variables**, and **relations** between these quantities. Measurements are to be of these quantities: if the **model** is adequate and reliable, the quantities correspond to properties of the **concrete system**...

"A measurement is a concrete **action**, which is not at the same **level** as the **model**, but at the **level** of the system, while on the contrary its interpretation is at the **level** of the **model**" (p.430).

DESTOUCHES adds: "... the word 'measurement' must be understood in a broad **meaning**, it denotes any manipulation and any explicitly formulated **method** designed in order to provide a positive empirical or experimental **knowledge** about the studied system... using as well an apparatus, a device, like a questionnaire, an inquest or a measure of samples, any **process** explicitly formulated, giving a **knowledge**, i.e. a result about the system" (1980, p.197).

D. GERNERT refined still more these views, insisting that: "A scientist decides *what* to measure (or to observe) and *how* to do it (decision phase)". The results must finally be interpreted by this initiator, who in most cases depends on devices and intermediaries (1994).

2048

MEASUREMENT SYSTEM²⁾

Set of concrete **elements**, organized in view of a measurement project and **method**, explicitly formulated and applicable to certain specific systems.

According to J.L. DESTOUCHES: "A **model** of this measurement system must be built, as well as a **model** of the measurement **process**, being it a physical, biological, or economical measurement" (1990, p.480).

The properties of the measurement system were stated by P. GONELLA (1976) and J.L. DESTOUCHES quotes them as follows: "A measurement device must produce a "measurement **signal**" shaped by the measurement **interaction**, which brings out some **information** about the measured **parameter**, and becomes elaborated by a chain of transducers, called measurement instruments, until it produces a "reading **signal**", received by the **observer** (which may be even another instrument).

"A **distinction** must be made between lecture (a **description** of the **output signal**) and the measurement (a **description** of the **signal** measured at the entry of the measurement device), which is expressed by a **set** of numbers related to the measurement unit. This is the "calibration relation" of the instrument which provides the **relation** between lecture and measure." (1990, p.480).

Thus, it is clear that any measurement is based on some preconception, depends of the characteristics of the instrument used, is generally registered in accordance with the perceptive capacity of the **receiver** and, finally, is interpreted in function of the **observer's model**.

Two more steps have entered the **process** under the form of computer **data** processing, which implies the sometimes hazardous translation of measurement **data** into a **data** system fit for computer use... and the final retranslation of the results.

2049

MEASURER²⁾

That **part** of a **regulator** which meets the **inputs** and **outputs** affecting the **process** or **function**.

The obtained **data** are needed to allow the comparing device, or **comparator**, to register **divergences** and, eventually, transmit these to the **effector**, for correction.

2050

MECHANICISM in CYBERNETICS¹⁾ - 3)

According to J.L. LE MOIGNE, the cybernetic **paradigm** may be considered "as an extreme form of the mecanicist **paradigm**" (1990, p.33).

This is in fact mainly the case of the **first cybernetics** as it was proposed and explained by N. WIENER who, as a practically oriented mathematician, insisted on the "**control** and **communication** in the animal and the **machine**".

It is indeed obvious that these first cybernetic **models** maintained a quite **reductionist** bias and were mainly applied to **stabilization** problems by introduction of strictly limitative **constraints**. It was mainly by the use of **negative feedback** that these were introduced, even if only a convenient sequence of **negative** and **positive feedbacks** is apt to produce a permanent **regulation**.

This initial cybernetic mechanicism made cybernetics quite suspect to psychologists and sociologists, who feared its possible use to justify or even organize some "Big Brother" type of social and individual **control**.

These qualms unfortunately closed their minds to M. MARUYAMA's **2nd Cybernetics** (**processes** of deviation and amplification by **mutual causality**) and still more so to the **cybernetics of 2nd order** of H von FOERSTER, related to **self-organizing systems**, and to the **conversation** concepts of G. PASK.

2051

MECHANISM ¹⁾

Any constructed device that can contribute to the **operation** of a **machine**.

To be reliable, a mechanism needs to present a foreseeable **behavior**. This supposes that it should be in principle entirely **deterministic**. This is for instance implied in classical celestial mechanics, as well as in the **operation** of any constructed appliance.

However, real mechanical devices are in the habit of breaking down because it is impossible in practice to endow them with rigorous **determinism** in front of unavoidable imperfections of their **elements** and unforeseeable **variations** in the conditions of their **operation**. This is also the case of purely mechanistic **models**, of which the theory of **deterministic chaos** shows the somewhat narrow limitations.

Mechanisms – either **models** of **machines** – are constructed by people, i.e. not self-constructed.

Even when quite complex, a mechanism can never be completely **autonomous**. It must be maintained and repaired by human experts. It is not **autopoietic**, i.e. it cannot reproduce its own **elements**, nor organize them in a **self-referent network**. The gap between machines and natural systems seems however to be narrowing (G.M. WHITESIDES, 1995, p.114-18), and foresaid may become less true in the future.

"Mechanism" is also frequently used in an **analogic** or **metaphoric** sense: the "mechanisms of economy", the "mechanisms of mind", etc... This is objectionable, because it introduces a conceptual bias into research and **models**.

2052

MECHANISM (Step) ²⁾

"A mechanism showing a **step function** as its main characteristic" (W.R. ASHBY, 1960, p.91).

This term was suggested to ASHBY by J.C. WISDOM.

Systems endowed with a step mechanism are able to switch their **behavior** from one **field** of **activity** to another one. ASHBY explain this in the following way: "Suppose, in a **state-determined** system, that some of the **variables** are due to step-mechanisms, and that these are ignored while the remainder (the main **variables**) are observed on many occasions by having their **field** constructed. Then, so long as no step-mechanism changes **value** during the construction, the main **variables** will be found to form a **state-determined** system, and to have a definite **field**. But on different occasions different fields may appear" (p.94-5).

Ashby adds:

"If the system had contained two step-mechanism, each of two **values**, there would have been four **fields** of the main **variables**. In general, n steps-mechanism, each of two **values**, will give 2^n **fields**. A moderate number of step-mechanism may thus give a very much larger number of **fields**" (p.95).

So, step-mechanism in systems explain how they remain **stable** ("ultrastable" in ASHBY's vocabulary) in a wide general **deterministic** sense, while however being able to adapt to a considerable **range** of variations, many times in a *seemingly random* way. Step-mechanism seem to open the way to **heterogeneity** and **complexity**.

For **changes** of field in an **ultrastable system** by **switching** at critical **states** through step-mechanisms, see ASHBY, 1960, p.96; figure 7/23/1.

2053

MECHANISTIC PARADIGM ³⁾

According to H.von FOERSTER and G. PASK, neither the **organism**, nor the **environment** can be identified with classical **automata** because, in this case neither can undergo any **change**. In such an **algorithmic** straight jacket, **adaptation** and **evolution** would be utterly impossible, as all possible **interactions** would have to be *strictly* predetermined.

The mechanistic paradigm produced mechanistic **models**, strictly **deterministic**, which could only "read" in nature very simple **causes** to **effects relations**. These **models** pervaded much of the conceptual outlook in **living** and in **human systems**, at least until 1960, and are still in some cases blocking a better **understanding** of truly **complex systems**.

The **thermodynamics of irreversible systems faraway from equilibrium**, the **catastrophe theory** and the **theory of chaos** seem to suggest that non-rigorously predetermined innovation remains always possible, even within the **frame** of **algorithms** formerly constructed by previous **evolution** and **learning**.

2054

MECHANIZATION ²⁾

"The **process** whereby the system makes the **transition** from the **state** of **wholeness** to the **state** of **summativity**." (I.V. BLAUBERG, V.N. SADOVSKY & E.G. YUDIN, 1977, p.55).

These authors state: "**Interaction** coefficients for each **element** of the system decrease and for $t \rightarrow \infty$ y tend to zero" (Ibid).

This implies that the system ceases to exist as such, being reduced to a number of unconnected **elements** (see the critique of the concept of **summativity**).

The term "mechanization" does not seem quite appropriate. Machines, even artificial ones, are made of more or less connected **elements**, which is how they become functional.

BERTALANFFY used the concept of mechanization, applied to systems, in a more satisfactory way.

2055

MECHANIZATION (Excessive) ^{1) - 4)}

D. KATZ and R.L. KAHN made the following comments (on human **organizations**, but of general interest for any strongly **integrated system**): "The typical **models** in organizational theorizing concentrate upon principles of internal functioning as if these problems were independent of **changes** in the **environment**..." (1966, p.100).

Such a limitation could also result of a too restrictive interpretation of the more recent concept of **organizational closure**.

The same authors add: "Moves toward tighter **integration** and **coordination** are made to insure **stability**, when **flexibility** may be the more important requirement. Moreover, **coordination** and **control** become ends in themselves rather than **means** to an end" (p.101).

These last comments are obviously relative to human **organizations**. It is however noteworthy that this tendency toward **rigidity**, here a result of a voluntarism unconscious of its own nature, can altogether be observed in **biological ageing** and in psychological disorders. It is possibly a result of **variety** exhaustion due to **constraints** increase resulting from continued readaptations to environmental **variations** and, more deeply to the unavoidable final entropization of any system.

2056

MECHANIZATION (Progressive)^{1) - 2)}

A **process** by which a system, at first governed by dynamic **interactions** of its **components**, acquires defined **structures** and **steady-state functions**.

This concept has been proposed by L.von BERTALANFFY as a general principle of **organization** (see "**Organization** as progressive mechanization").

D. KATZ and R.L. KAHN state this idea in the following way: "*early growth* is a **process** which involves an **interaction** of various dynamic forces, whereas the latter development entails the use of a regulating **feedback mechanism**" (1966, p.99).

In other words, the original "organizational dynamism" of the system, starting from its **auto-genesis**, is the motor of its **morphogenesis** and exhausts itself when the system matures.

2057

MEDIA^{1) - 4)}

"A generic term for systems of production and dissemination of **information** and entertainment".

Media, formerly limited to printed material, underwent a massive development during the 20th Century.

They are characterized by the possibility offered to individual senders – who anyhow are generally mere spokeswomen or men for some known or unknown **deciders** – to reach thousands or millions of **receivers**. Moreover, the **transmission of messages** is unilateral and can easily and artfully be used to condition the **receivers**, who have very scant practical possibilities of critical **feedback**. A result, as observed by K. KRIPPENDORFF, author of the definition, media are widely used to exert "various kinds of social **control**" (1986, p.48).

2058

MEDIATION^{1) - 4)}

The **activity** of a device or **subsystem** that connects and organizes the production of selected **subnets** in a certain way and according to certain specific needs.

A. and H. DAMASIO introduce what they call "mediation systems" as intermediates "... between the **brain's** concept-**processing** systems and those that generate words and sentences" (1992, p.70).

They show that **perturbations** in this **mechanism** explain many "neural brokerage" impairments as, for example, the impossibility to connect a person's face with her name.

The mediation **concept** seems to be a rediscovery of J. G. MILLER's **associator subsystem**.

Mediation **subsystems** do also probably exist in insect societies and certainly in human ones, where numerous **coordination groups** and devices of the most varied kinds can be recognized.

They probably will become a necessity in decentralized **artificial intelligence** systems, in which coordinated **interactions** are a very basic need.

2059

MEDIUM¹⁾

A region in **space-time** endowed with relative permanence where observable **events** take place.

"Observable" **events** are such for **living systems** endowed with *specific* capacity of **perception**. As observed by J.J. GIBSON, each medium induces a defined potential specifically adapted to possible **behavior** for a specific **living system**.

See: "**Affordance**".

Water induces specific **behavior** in a fish, and different ones in a swimming terrestrial mammal, or in a marine bird, like a penguin. And air induces a type of **behavior** in a flying bird, another in a butterfly, and another still in an aircraft's pilot. (1986, p.16-19).

A medium should be distinguished from an **environment**, which already implies a clear partition between some system and the non-system which whom it interrelates: such **environment** does not necessarily includes the whole medium.

Besides, as noted by E. MORIN: "The medium is not a stable setting, but a region where **events** surge" (1972, p.9).

A dynamically structured medium would be a **field** (see Ch. LAVILLE describing biological mechanisms considered from the atom to the living systems, 1950).

2060

MEMBERSHIP FUNCTION

→ Fuzzy sets (Theory of)

2061

MEMBRANE^{2) - 5)}

A thin film of chemical or biological **matter** that constitutes the specifically permeable **boundary** between a system and its **environment**.

Membranes are **interfaces** which selectively in **space** and **time** allow or inhibit the transference of **inputs** and **outputs** from the **environment** to the system and vice-versa. Membranes are as much connective devices as **separators**.

Some cosmologists and physicists recently started to use the strange neologism "brane" (= shortshrift for membrane) to signify the hypothetical divisions in-between the numerous dimensions now postulated in some theories about the **universe** (or universes)

2062

MEME^{1) - 4)}

"A unit of imitation" (R. DAWKINS, 1978, p.206).

DAWKINS introduces this neologism as a specific kind of **replicator** in human culture, "... a noun that conveys the idea of a unit of cultural transmission" (Ibid). The term should have been "mimeme" (as in mimic), but DAWKINS wanted "... a monosyllable that sounds a bit like gene" (Ibid)

"Examples of memes are tunes, ideas, catch-phrases, clothes fashions, ways of making pots or building arches. Just as genes propagate themselves in the gene pool by leaping from body to body via sperms or eggs, so meme propagate themselves in the meme pool by leaping from **brain** to **brain** via a **process** which, in the broad sense, can be called imitation" (Ibid). N.K. HUMPHREY, a colleague of DAWKINS, summed all this up in this way: "... When you plant a fertile meme in my mind you literally parasitize my **brain**, turning it into a vehicle for the meme's propagation in just the way that a virus may parasitize the genetic **mechanism** of a host cell" (Ibid, p.207). Some kind of covert brainwashing!

J.T. BONNER observes: "The thing that sets memes apart is that they are learned by one individual from another, and they are not present in the DNA of the genes. Therefore, if an animal is removed from its mother before birth and raised in the absence of any of its own kind, it will lack all the memes that its family might have passed on, while it will retain all the genes that its parents bestowed upon it" (1988, p.209). So-called wolfchildren are a good example (J.A. SINGH and R.M. ZINGG, 1942).

A culture is characterized by a particular **population** of memes: a meme pool.

C.J. LUMSDEN and E.O. WILSON (1981) proposed the equivalent term of "mentifacts" and C.P. SWANSON (1983) the term "sociogenes" (quoted by G.R. JOHNSON, 1992).

According to S. BLACKMORE a full fledged meme implies more than simple copying some **behavior** or concept. Three additional criteria should be needed:

- The **message** must be accurately copied
- Many copies must be made
- The copies must last a long time" (L.A. DUGATKIN, 2000, p.55).

BLACKMORE gives the following list of memes and complexes of memes (2000, p.54):

MEMES	COMPLEXES OF MEMES
"Stories, urban legends, myths	Beliefs in UFOs, ghosts, Santa Claus
Clothing, hair styles, body piercing	Racist slogans, sexist jokes
Cuisine, cigarette smoking	Religions
Applauding, cheering	Inventions, theories, science
Languages, accents, catch phrases	Judicial systems, democracy
Songs, music, dances	Proust's story of the madeleine cake"

2063

MEME COMPLEX^{1) - 4)}

"A co-adapted stable **set** of mutually -assisting memes" (R. DAWKINS, 1978, p.212).

Memes complexes are created by **consensus** about the **significance** given to some **signs** and start being transmitted after such recognition. It is in this sense that G.R. JOHNSON may write that "...**information** exchange is really nothing more than a **metaphor** for biological **action** at a distance, i.e., the influence of one nervous system on other nervous systems through the production of physicochemical **stimuli** to which those other nervous systems are sensitive" (1992, p.1143). Or "A speaker says something that is a product of prior genotype-**environment interactions** and his or her current **environment**. A listener exposed to this **behavior** responds on the basis of his or her prior genotype-**environment interactions** and current **environment**" (p.1145).

DAWKINS states that we could perhaps regard as an example "... an organized church, with its architecture, rituals, laws, music, art, and written tradition" (ibid).

Meme complexes have obviously a strong tendency to propagate in **space** and a great survival power in **time**.

→ **Frame of reference**

2064

MEMEPLEX¹⁾⁴⁾

An interconnected **set** of **memes**. (a neologism)

Co-adapted **memes** complexes "include **languages**, religions, scientific theories, political ideologies and **belief** systems such as acupuncture or astrology. Like **memes**, memeplexes spread as long as there is some reason for them to be copied. Some are true or useful, other are copied despite being false" (S. BLACKMORE, 1999, p.44).

The memeplex is a kind of general **model** for widely shared and transmitted **knowledge** or beliefs in societies.

Remains to be seen how it can be connected with some physical **communication** means, as for example **integrate and fire mechanisms** that could take place between human **brains**.

2065

MEMETICS¹⁾⁴⁾

The study of the way **memes** translate from one individual to others, and of their effects.

R. DAWKINS, who introduced the concept of memes, and Susan BLACKMORE are the main promoters of memetics, which appears to be on its way to become a new discipline. It seeks to investigate the ways memes appear, become accepted and spread after the crossing of a critical **threshold**. (M. GLADWELL, 2000).

As such, it seems to point toward a deep reworking of some of our psychological and sociological **concepts** and **models**. It is obvious for example that religious **beliefs**, or **ideologies**, rumors and even fashions and fads do propagate in ways similar to **epidemics**.

According to a recent article by Susan BLACKMORE (1999, p.40-44), it could also lead to new insights about the deeper **meaning** of Buddhist psychology.

Memetics seems as well related to the "**mindbugs**" described by J. WARFIELD.

They are originally at least in part a biological metaphor, which could of course be in time elevated to the level of a workable analogy, leading to useful conceptual isomorphisms.

→ **Clanthink; Effects (Herd); Network; Percolation; Propagule; Runaway process; Small world**

2066

MEMORY²⁾

"The **subsystem** which carries out the second stage of the **learning process**, storing **information** in the system for different **periods of time**, and retrieves it".

This is one of J. MILLER's **20 critical subsystems** in **living systems** (1978, p.3). It does for **information** what the **matter-energy storage subsystem** does with **matter** and/or **energy**.

2067

MEMORY AND NOISE^{1) - 2)}

Memory is able to built itself (in whatever form) only by orderly integrating **noises** into already existing informed sequences.

In this way, there is an increase of **information** in the system... But the price that must paid for it is a decrease of **redundancy**, i.e. **serves** of internal unused potential **states** usable to counteract external **variety** introduced by **noise**.

Thus, memory as a **process** uses up its potential as it enrich itself.

This understanding of memory as an accumulative, but self limiting **process** of **organization**, is significant for biological as well as **socio-cultural systems** limited **survival**.

2068

MEMORY (Associative)²⁾

The capacity of various **elements** or **subnets** in a **network** to collectively retrieve and share **data** existing in the **network**.

In a quite close sense, M. BODEN speaks of "**contextual** memory", through which: "an **input pattern** can activate not only a similar **pattern**, but also some aspects of its previous **context**... An apple in a religious painting may remind you of Eve, whereas an apple in a still-life does not)" (1990, p.119).

It becomes evermore obvious that associative memory is the potential ability which enables the living **brain** to easily assemble existing **data** into very complex **representations** and perform quite difficult chores in very short spans of time. Associative memory seems to be preexistent to its uses, in the form of **frames of reference**, which express specific aspects of **organizational closure**.

Parallel distributed processing in **connection machines** (connectionist architectures) is now trying to emulate this ability.

2069

MEMORY (Computer)^{3) - 5)}

The often used analogy of computers memory with memory as a **function** of the **brain** is very misleading, as strongly emphasized by H.von FOERSTER in many of his papers (1981).

This author pointed out that, "Unfortunately, some anthropomorphically inclined quipsters have dubbed the **storage** system "memory", and henceforth, some naive psychologists – and, alas, some neurophysiologists – who believed the engineers to know what they were talking about, kept looking for **analogues** of magnetic tapes, discs, cores and drums within the nervous system" (Quoted by K.L. WILSON, 1979, p.31).

This is of course a quite demonstrative example of abuse of **metaphor** and even unwarranted **analogy**.

A computer's so-called "memory" is in effect a **data storage device**, which contains records, "... also the name properly given... in the pre-**semantic** confusion times... to those thin black disks which play back the music recorded on them" (1981, p.236). **Data** simply occupy some room on a hard disk or on a diskette. A **datum** can be searched for and found in a specific place, while the **brain** has no very

specific places where "something" would be stored. It rather seems to be more of an organized, modifiable, but altogether **autopoietic network** of subnetworks.

2070

MEMORY (Distributed)²⁾

The redundant sharing among numerous **elements** interconnected in a **complex system** of **parts** of the total available **information** present within the system.

Better than to speak about memory as a global **function**, we should consider different types of memories: visual, auditive, lexical, semantic, etc..., which work in different conditions and at different **time scales**.

This type of distributed memory is found in **complex systems** under the form of intercommunicated **nets** among numerous **elements**.

The **brain**, or human **organizations** and societies, or **populations** from the genetic viewpoint seem to be good examples.

No single **element** does possess the total stock of **information** of the system, much less so. However numerous **elements** do share some **data**, or characteristics, or **knowledge**. The positive aspect of this kind of **holographic** or **heterarchic** arrangement is that the destruction of a **part**, even important, of the system does not lead to the loss of much **information**, since the surviving **elements** (neurons, genes or individuals) still possess most of it and are able to retransmit it within a reconstructed **net**.

In order to maintain (or create) **coherence** in such type of distributed memory, some kind **organization in levels** is however needed. We have thus a mix of **heterarchic** and **hierarchic order**.

von FOERSTER introduced the concept of "memory without a record". Memory is not a set of records stored in some specific place in the **brain**: the computer memory is an incorrect **metaphor**.

L. M. ROCHA comments: "By utilizing functionals to change the **functions** of **state-determined** systems, von FOERSTER formalized the idea that memory can be observed in systems which are able to change their own **structure** and therefore its dynamics and **attractor behavior**. Today we name this kind of memory distributed, and the kind of **models** of memory so attained as **connectionist**. The **categories** that a distributed memory system classifies are not stored in any particular **location**, they are nowhere to be found since they are distributed over the entire **dynamics** established by some **network** of **processes** (van GELDER, 1991). They exist however in the form of **attractors** (**eigenstates**) which are nonetheless discrete" (1996, p.377)

This **model** of memory is closely related to **organizational closure**, characteristic of **autopoietic systems**.

It leads to "distributed memory selected **self-organization**" (Ibid)

→ **Distributed meaning (Principle of)**

2071

MEMORY IN ECOSYSTEMS AND SOCIETY¹⁾⁴⁾

J. SENDZIMIR and H.T. ODUM observe that:

"General systems **analogs** of **short term** and **long term** memory are found within ecological succession, **evolution**, internet, and the development of human **culture**. Estimates of **energy** and **transformity** are used to evaluate the **resource** basis for **information** and its **maintenance**" (1998, p. 154)

They add that these values can be "used to consider the **limits** to information in our civilization and suggest policies consistent for global sharing" (Ibid.)

2072

MEMORY (MILLER)^{2) - 3)}

A registered trace of some former **stimulus** and its results, in a **living** or an artificial **system**...

or, the capacity to store perceived **information** for later retrieval, generally in a modified form.

According to K. KRIPPENDORFF, memories are observational **constructs** (1986, p.48).

However M. BUNGE writes that "... memory is the activation of neural **connections**", while "**learning** is the formation of neural **connections**" (1979, p.138).

It seems not yet very clear if these **connections** are merely a potential to be evoked or if they exist permanently.

The first definition, inspired by R.L. ACKOFF and F.E. EMERY (1972, p.76), "... does not require that the memory-**response** be a conscious one".

The same authors define the intensity of a memory as "... the intensity of the **response** that defines it"; the durability of the memory "as the length of **time** over which it persists", and the correctness of the memory as "the **efficiency** of the memory **response** for the **objective** for which it is intended" (p.77).

"Memory" has been a very controversial **concept** among systemists, cyberneticians and computer scientists.

H.von FOERSTER writes: "Let me demonstrate the notion that is computing, rather than signaling and storing these **signals**, which is at the core of **cognitive processes** by contemplating for a moment "memory". For it is precisely the misconception of this higher mental **function** to be a "data storage system" which blocks the vision for the kind of systems we shall need to meet the challenge of the future.

"If memory were a **data storage system** it is easy to show that in order to account for what we know, each of our brains should be the size of a sphere about one mile in diameter packed with nerve cells. However, when of this size, the **operation** to recognize, for instance, the presence of a lion in its field of vision takes this **brain** about ten years. This may be helpful for the lion but, alas, not for the bearer of this **brain**" (1982, p.216).

In synthesis, what our **brain** does is *not* going searching for one specific **datum** in a colossal heap of stored **data**. In von FOERSTER's terms: "... (it) computes the answer to a question, rather than store all answers together with all possible questions in order to respond with the answer... when it can find the question" (p.175).

According to von FOERSTER, we should view memory as a *process* property of the **brain**: "... as if it were a computer whose internal **organization** changes as a result of its **interaction** with an **environment** that possesses some **order**. The **changes** of the internal **organization** of the computer take place in such a way that some **constraints** in the **environment** which are responsible for its orderliness are **mapped** into the computer's **structure**. This **homomorphism "environment-system"** reveals itself as "memory" and permits the system to function as an inductive **inference computer**" (p.114).

Moreover, the main practical feature of cognitive processing in relation to **memory** is that "cognitive living **organisms**... succeed to eliminate quickly all temporal aspects in a sequence of **events** or, in other words,... "time" is abandoned as early as possible in the chain of **cognitive processes**" (1982, p.140) (i.e. the only way to save oneself from the "lion's jaws!").

von FOERSTER wrote this in 1965, when **networks** and **connection machines** had not yet entered into the main currents of **cybernetics** and systems science. Thus the use of the term "computer" should not be taken as meaning any identification of **brains** with classical **sequential** computers which process stored **data** according to strictly deterministic or even stochastic **programs**.

2073

MEMORY OF INITIAL CONDITIONS¹⁾

A perfectly reversible system could be considered as having a perfect memory of its initial conditions, inscribed in its **history**, and thus be able to backtrack to its initial **state**.

This is however not the case for any **concrete system**, with many initial conditions whose **effects** interact in new ways at any instant. As stated by K. BERRIEN: "All memories in any form decay, some at an infinitesimal **rate**. The print of books fade, ... magnetic **patterns** dissipate, and, evidently, whatever the neural traces may be, they vanish. Even if we

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

conceive of **storage** as any *potential energy*, the **second law of thermodynamics** carries with it the increase in **entropy** as an inevitable degradation of all **energies**... Memory can be conceived to be a stored **change** in a system as a consequence of **signal inputs** that are maintained longer by appropriate **maintenance inputs**" (1968, p.42-3).

In BOLTZMANN's statistical interpretation, **entropy** leads the ideally **isolated system** toward maximum molecular **disorder**, i. e. away from any memory of its particular initial and **dissymmetric** conditions.

In turn, any **concrete complex system** must necessarily be highly **dissymmetric** and maintain itself within the **limits** of a **global determinism** which defines its general conditions of existence. But such a **global determinism** allows for local and transient conditions, which may be unconnected *for a while*, and later on recombine in very variable ways, within however the **limits** of the **global determinism**. The **set** of the initial conditions becomes probably blurred during this **process** and possibly disseminated among numerous **elements** or **sub-systems**, as for example, in **populations** or **social systems**.

In this way, the "memory" of initial conditions is not lost, but becomes scattered and can never be fully recovered and reintegrated.

Such a situation may be clearly observed, for example, in the **Markovian matrixes** used by W.R. ASHBY for the study of **populations behavior** (1956, n°9/6).

According to a curious comment by R. THOM, "A solid is quite static. But its interest is that it is a depository of past **actions**, which makes it interesting for the interpretations of **forms**. It is a memory. A liquid has scant memory and a gas, still less, since it takes the **form** of the container in which it is stored" (1991, p.49).

2074

MEMORY (TAXON)

→ **Taxon Memory**

2075

MERIDIAL²⁾

Character of a **translation** along a meridian, or crossing a torus orthogonally to annular **paths**.

This neologism has been introduced by D. Mc NEIL in relation to his general **model** of systems as **toroids**. (pers. comm.)

2076

MESO-¹⁾⁴⁾

A prefix that indicates that some entity corresponds to an intermediate **level** in a **classification**.

Such **classification** can be temporal or spatial.

For ex. "mesolithic" is more recent than paleolithic, but older than neolithic, in archeology.

In **space dimensions**, meso- is bigger than **micro-** and smaller than **macro-**, or **mega-**. M. BUNGE f. ex. describes a big business or a university as mesosocial systems, inbetween families (micro-social) and transnational businesses or the United Nations (mega-social) (1995, p.35)

2077

MESOSCOPIC SCALE

→ **Scale (Mesoscopic)**

2078

MESS^{1) - 4)}

"A system of problems that cannot be decomposed in more simple problems... which themselves are minimeses" (R.L. ACKOFF, 1974, p.21).

"By "mess" ACKOFF means that every human **problem** is associated and involved inextricably with every other human **problem**" (I.I. MITROFF and H.A. LINSTONE, 1993, p.47-8).

Messes are quite frequent in technical, economical and socio-political systems, and result of their **complexity** and **nonlinear** character, which are neither perceived, nor taken into account.

Specific **action** on one or some few **elements** selected within the system does not normally produce the forecasted or expected **effects**, because it is taken unknowingly against some other functional needs of the system.

Messes have a tendency to expand very far from their origin in **space** and **time**, and to pop up again under unexpected aspects.

However, a mess may also offer new opportunities to an acute manager.

ACKOFF has given a considerable number of examples of messes that he met in his career as a consultant.

The basic requirement to manage a mess and make it produce opportunities is trying to focus it from an original angle, which can be understood and appreciated by all **stakeholders**.

In the numerous cases in which a mess affects a natural system or an artificial technological one, human **components** play a most generally basic role.

2079

MESS FORMULATION^{2) - 4)}

Identification of the system of problems and opportunities (in a mess) and **understanding** of the **pattern** of **interactions** among these problems and opportunities, and **constraints** on the **organization's** ability to do something about them (after R. HARNDEN, 1990, p.344).

According to R.L. ACKOFF, a good way to formulate the mess is projecting the future of the **organization** or enterprise if nothing would be done to clean up the mess.

Three aspects are of particular importance:

- obtain a detailed **description** of the **organization** and how it works, internally and in relation to its **environment**
- study the obstructions that block the smooth **development** of the **organization**
- prepare projections extrapolating the present **performance** of the **organization** in its messy conditions, in order to discover the dangers that loom ahead.

HARNDEN states: "The depth of analysis carried out in the mess formulation makes it possible to dissolve **conflict**. It is in this phase that the focus on **learning** is dominant. A proper mess formulation probes deeply and honestly enough to demonstrate to any doubting party that the approach is balanced and respects everyone's **issue**. In mess formulation, the **issues** are reframed until they are stated in terms that recognize existing interests vital to all **parts** and create a shared **purpose**" (p.845).

This view is very close to **co-participative design** (BANATHY - FUSCHL Group), **heterarchical design** (JOHANNESSEN) and **generic design** (WARFIELD).

2080

MESSAGE^{1) - 2) - 3)}

"A **set** of one or more **signs** intended by its producer to evoke a **response** either in another or in himself" (R.L. ACKOFF & F. EMERY, 1972, p.176).

"A scaled and integrated **signal** which has significance or **meaning** for either the **transmitter** in transmitted messages or the **receiver** in received messages" (Ibid, p.272).

Both definitions are very general, in a systemic sense: a message is anything that transmits **information** of any kind (positional, genetic, through gesture, iconic, verbal, symbolic, etc...).

J.de ROSNAY states: "A message is composed of **signals**, **signs** or **symbols** assembled according to a **code**" and adds: "A **set** of messages and **codes** constitutes a **language**... The message emitted from a **source** is codified and next, transmitted through a **channel**..."

Moreover: "... **perturbations** interfering within the **channel**, which are called **noise**, may alter the messages and modify their **significance**" (1975, p.168-9).

Noise may even turn them incomprehensible. But in many cases, they can be recuperated by adequate filtering.

Messages can be compressed, by eliminating **redundancy**, but with an increased risk to their intelligibility due to perturbing **noise** (D. RUELE, 1991, p. 175).

It is interesting to observe that, while a 100% **redundant** message carries no **information** at all, a 100% original message, would not be intelligible, save if it conveyed implicit connotations. Both types are very difficult to produce in practice.

For example, the totally imaginary and senseless word "facrupto" can at least be written in Latin **alphabet**, tentatively pronounced as an English, or French, or Spanish word... and may even in the future become a known example of 100% original non intelligible **information**!

2081

MESSAGE (Ambiguous)^{2) - 3)}

A message thus transmitted that the **receiver** remains unsure of its **meaning**.

The **ambiguity** is generally the result of uncertainty about the **context**, as for example in the case of humour when we are not yet sure where the joke is leading us, or when an imprecise question allows for different replies, as in oracular pronouncements. The problem of **ambiguity** shows that any message is merely a specific combination of some **elements** within a linguistic and situational environment.

→ **Meaninglessness**

2082

MESSAGE in its epistemic environment³⁾

Electronic and human messages are different as the first ones are technically based and the latter ones are **semantically** based, after of course being transmitted through a physical medium.

As explained by L. THAYER: "... in electronic **communication**... the **transmitter** has been designed and programmed to send and the **receiver** has been designed and programmed to receive (and sometimes to process in some way)" (1972, p.101).

Ambiguity in coding is proscribed and **redundancy** is used to eliminate **noise** as completely as possible: "... the "message" must be **invariant** for the **transmitter** and the **receiver** under all conditions. This is the whole point of reliable **communication**" (Ibid).

THAYER pursues: "For humans, on the other hand, the "message" (which itself is a misnomer) must vary with the **context**" (Ibid). This means that the same message in different circumstances or places may be received and interpreted in quite different fashion by different **receivers**. The significance may heavily depend on what B. HOLZNER (quoted by THAYER) calls the "**epistemic community**" in which it is emitted and received.

THAYER adds the important following comment: "Closely related is the conceptual confusion that has resulted from analogizing the concept of "**information**" from electronic **communication theory**, **information theory**, and **cybernetics** into the study of human **communication**" (Ibid).

This kind of "electronic **reductionism**" goes a long way to explain psychologists and sociologists resistance to the **cybernetic** concepts in general, and even their belief that **cybernetics** is not much more than manipulative gadgetry.

2083

MESSAGE (Meta-)^{2) - 3)}

A message on a higher **level** that may modify the interpretation originally given to the message.

G. BATESON gives the following example: "I was lying when I said "The cat is on the mat" (1973, p.218).

He comments: "(this) tells the vis-a-vis nothing about the location of the cat. It tells him only something about the reality of his previous **information**... The **context** (or metamessage) *classifies* the messages, but can never meet it on equal terms" (Ibid).

→ "**Metacommunication**"

2084

MESSAGES (Hierarchies of)³⁾

G. BATESON observes: "... that messages may be about (or 'meta') to the **relationship** between messages of different **levels**" (1973, p.219).

2d order learning is based on **processes** of hierarchization of messages. A good example is Pavlovian conditioning, wherein the **metamessage** comes finally to act as **trigger** for the conditioned **behavior**.

Behavioral and mental **algorithms** act as **contexts** or **metaccontexts** for the interpretation of messages.

2085

META^{1) - 2)}

A prefix used to indicate a higher **level of complexity** or **abstraction**, referring to **models**, **languages**, or systems.

This prefix, mainly diffused by J.van GIGCH and his collaborators, has been occasionally criticized by some users on the ground of its supposed philosophical connotations and arguing that it could be replaced by "**supra-**" or "**super-**".

It is, however, widely used and does not seem to entail **semantic** confusion. Moreover, its meaning is solidly grounded in B. RUSSELL's and A.N. WHITEHEAD's **Theory of logical types**.

E. SCHWARZ observes that it has frequently a **self-referential meaning**: "Examples: **Meta-knowledge**, as **knowledge** on **knowledge**; meta-mathematics, as **mathematics** of the **mathematics**; **meta-communication**, as **communication** about **communication**" (1993, p.7).

Meta- can also imply a **transition** from one **state** or **process** to another, as for example in **metabolism**; or some kind of **generalization**, as when systemics is spoken of as a **metalan-guage**.

2086

META-ANALYSIS²⁾³⁾

"A way of extracting statistically meaningful **information** from lots of small trials" (The Economist, sept. 27th, 1997)

The Economist adds: "... even if they have been conducted in ways that make them difficult to compare "by eye". Its conclusions, however, are only valid if the negative trials are included as well as the positive ones. Leave out the negative ones and the results may be too optimistic".

Such a **method** applied to scientific **experiments** may obviate undue rejections as well as conniving acceptances in the classical process of peer review.

2087

METABOLISM⁵⁾

The **set** of (**synchronic** and **diachronic**) **transformations** which occur in a **living system** and allow it to maintain its **identity** through **homeostatic processes**.

Metabolism is an internal **process** within a system

It follows **rules** that must necessarily be in accordance with the characteristics of the system

For ex. a **living system** cannot metabolize strychnine

These **transformations** are principally biochemical and biological and affect the **matter** and **energy flows** which enter into the system. L.von BERTALANFFY wrote that: "Metabolism is the **maintenance** in a **steady state**" (1969, p.80).

This notion could be generalized:

- 1) to the **transformations** affecting the **information** received by the system;
- 2) to the **meta-living systems** that also transform energy, **matter** and **information**, obtained from their **environment**.

2088

METACOMMUNICATION^{2) - 3)}

A key for **decoding communication**.

The concept is introduced and thus explained by M. MARUYAMA: "Metacommunication is a "decoding key", but *not* the **content** of the **communication**. For example, if I send a mes-

sage, "It is raining in New York", and send another **message**, "The first **message** is false", then the second **message** is a **decoding** key for the first **message**, telling you that a joking **mode** or a deceptive **mode** was used. But the second **message** by itself does not say anything about the weather in New York" (1994, p.69).

Metacommunication may lead to **double-bind situations**, as with the famous Epimenides-the-liar paradox (see "Theory of types", "Metamessage").

Metacommunication thus frames and relativizes **communication**. This is very significant, especially when metacommunication remains implicit, as it is the case in many transcultural **situations**. Transculturated individuals can become victims of their ignorance of implicit metacommunication in the other culture.

2089

META-CONCEPTS^{1) - 3)}

Those concepts of very general character whose span of **validity** covers numerous different types of **situations** and systems.

All **cybernetic** and systemic concepts are meta-concepts. The interconnected **set** of systemic meta-concepts constitutes a **metalinguage** within which specific statements originating in some discipline can be generalized. They can thus be used to emphasize significant **analogies** and **isomorphisms** between the **models** we may construct in different disciplines, related to different systems.

For example, **feedbacks** can be observed in many physical, biological, human and artificial systems, and **autopoiesis** is proper to any kind of **living systems** or systems made of **living systems** (i.e. **social systems**).

Cybernetic and systemic meta-concepts provide guidelines for **transdisciplinarity** because they offer a common **metalinguage** and **meta-models** to specialists, a way to obtain **meta-skills** and avoid costly errors when participating in complex projects.

2090

META-CYCLE²⁾

"A cycle which **embeds** cycles of smaller **periods** and **amplitudes**"

→ **Fractals**; **Self-similarity**; **WEIERSTRASS function**

2091

METAKNOWLEDGE IN CRITICAL THINKING³⁾

J.van GIGCH defines metaknowledge as "knowledge about knowledge". He writes: "We agree with PITRAT (1985) that we must possess metaknowledge in order to be able to evaluate knowledge. Every time that we take **object-level** knowledge through the dialectic **process** of validating logic or raising **abstraction**, we

produce metaknowledge; PITRAT postulates the existence of knowledge and metaknowledge, but rules out the existence of meta-metaknowledge. We disagree with PITRAT, but argue that our disagreement is probably only a matter of definition...

"The **recursivity** of the **dialectic process** ensures that there is always a **metalevel** to which we can resort to prove the logical and **truth validity** of statements. The **recursive** property is only diminished by practical considerations, such as time and **cost**, and by theoretical limits, as stated in **GÖDEL's theorem**, a subject that will be avoided here" (1987, p.325).

It must be said that van GIGCH defines **truth** as meant here as "the **meaning** of a claim in the **context** of its knowledge **domain**".

As to GÖDEL's theorem, it is in any case the foundation of hierarchical **levels** of knowledge, even if it implies a final doubt about limitless **recursivity**. (C. FRANÇOIS, 1993, p.57-76)

van GIGCH also explains: "As knowledge is reconceptualized through the interplay of ever higher **levels of abstraction**, it becomes more complex and hence less liable to modification and **change**. Therefore we contend that knowledge pertaining to higher conceptualization **levels** (metaknowledge) is more difficult to change than knowledge from lower conceptualization **levels** (**object level** knowledge).

The best reason which we can give of this increase in **complexity** is that as we change **paradigm** to explain a new set of **facts**, the new **paradigm** must confront the **validity** of two propositions:

- 1. why the old **paradigm** cannot explain the new **facts**;
- 2. why the old **paradigm** was sufficient to explain the old set of **facts**.

The new **paradigm** has a more complex **set** of propositions to explain than the old one" (1986b, p.97).

→ See also: **Structural differential**

2092

METALANGUAGE³⁾

1) "A language of a higher **order** of logic which is spoken at the **metasystemic level**" (J.van GIGCH, 1986a, p.3 – after St. BEER).

2) A **code** used for speaking or studying another language" (J.Z. YOUNG, 1974, p.295).

J.van GIGCH adds: "Metalanguages are needed to resolve debates, conflicts or **undecidability** which cannot be resolved in the language or logical **structure** of systems at the **object level**" (Idem).

The necessity and nature of metalanguages became obvious after A.N. WHITEHEAD and B. RUSSELL's **Theory of types** and still more so after **GÖDEL's theorem**.

Anyhow, **undecidability** always reappears at the higher considered **level**.

2093

META-LANGUAGE Characteristic requirements^{2) - 3)}

According to BLAUBERG et al: "There are two basic requirements for the meta-language: 1. it must include the language-object (all the expressions of the language-object must be translatable into those of the meta-language), and

2. it must be richer logically than the language-object (it must have the necessary logical means for describing the **structure** and other properties of the language-object)" (1977, p.198-9).

It seems quite possible that only some of the concepts of **general systems theory** could be translated into a formalized meta-language, as stated by BLAUBERG et al. themselves.

2094

METALINGUISTIC RULES³⁾

"The rules which govern how words and sentences shall be related to **objects** and **events**" (G. BATESON, 1973, p.153).

BATESON states: "Denotative **communication** as it occurs at the human **level** is only possible *after* the evolution of a complex **set** of metalinguistic **rules**...

"It is therefore appropriate to look for the **evolution** of such metalinguistic and/or meta-communicative **rules** at pre-human and pre-verbal **level**" (Ibid).

For a thorough exploration of this subject, see A. KORZYBSKI's "Science and Sanity" (1950).

2095

META-METAMODELING^{3) - 4)}

The ultimate **frame** for **validation** of **decision making**, where cultural and social basic **values** are taken into consideration.

At the **decision making level**, sound **modeling** and **metamodeling** do not yet suffice, as no **design** or project can prosper, nor be willingly and definitively accepted without a reasonable **consensus** of all **stakeholders**.

2096

METAMETHODOLOGICAL INQUIRY^{2) - 3)}

An investigation "regarding **systems methodologies** rather than **knowledge** regarding systems" (G. KLIR, 1991, p. 106).

KLIR explains how any particular **systems methodology** can be compared with others. "Metamethodological inquiry can also be employed for validating various methodological principles that are based upon the investigated **methodologies**" (Ibid).

KLIR asserts that computers are very convenient tools for this kind of inquiries.

2097

METAMODEL²⁾ - 3)

"A **model** of a higher **level of abstraction** which ...maps the properties of lower systems **models** into propositions of a higher **level of abstraction**" (J.van GIGCH, 1987, p.3) (after St. BEER).

To this definition, van GIGCH adds the following comment: "Of necessity, the metamodel is conceptualized in a metasystemic **language** or metalogic which can decide propositions and reconcile arguments which cannot be decided or reconciled in the **language** of logic of lower systems **models**" (p.3).

The unavoidable need for **validation** through metamodels is closely related to **GÖDEL's theorem**.

2098

METAMODELING²⁾ - 3)

"A **process of design** which is carried out at the **metalevel**, and by which we define how the **process of modeling** (at the **object level of abstraction**), is to be carried out. (J.van GIGCH, 1992 p.3)

In another work, van GIGCH commented: "Until recently, the accepted approach to **problem-solving** consisted of the formulation of a **model** and applying the solution obtained from the **model** to the real world. However, this **methodology** bypasses the important step of metamodeling, that is setting the **rules** of logic by which the **model** itself is to be designed. Metamodeling, or the Science of Modeling, is involved with designing **metamodels** and with designing the **process of design**" (1978, p.3).

In his more recent paper, van GIGCH adds: "Metamodeling defines the **epistemology** or **design foundations of modeling**", (thus establishing the foundations "... of the reasoning **process**, guarantees of **truth**, proofs, axioms of **validity**, or any other logic which underlies a **methodology**" (Ibid).

Decision making should ever be framed within a **metamodeling level**, which implicitly involves cultural and social **values**: It is now time to verify the **fitness** of any **model**, specially those of **complex systems** (frequently very much partial and biased as they are), in order to protect ourselves against the **side effects** that some important but neglected aspects of the modeled **situation** may bring in their wake.

2099

METAMORPH¹⁾ - 2)

A more **complex system** resulting from the recombination of characters formerly unconnected.

This happens more or less frequently in **heterogeneous populations**.

Metamorphs appear frequently in technological **evolution**. C. FARRELL gives a curious example: "... metamorphs arise when disparate ideas are brought together - such as writing and playing piano. Combine them, and you get the first typewriter, which actually used keys from a piano" (1993, p.39).

Another metamorph is the "motor-car", literally, a cart or chariot equipped with a motor!

2100

METAPATTERN: a pattern of patterns¹⁾²⁾

The concept has been introduced by G. BATESON (1979). In each of the different **levels of complexity** of a system, some pattern can be distinguished for the **description** of the ways the **elements** at that level interconnect and interact.

As observed by BATESON, no order of **interaction** among **elements** can be totally independent from its **context**, be it co-systems, or higher or lower **levels** within the system, or some features external to the system as a **whole**.

This **dependence**, or **interdependence** implies the existence of higher (or lower) **patterns** of interactions which are in some way related to the pattern originally considered.

These **relationships** between different patterns can be named metapatterns

As expressed by BATESON "without context, there is no **meaning**". This is why a supposedly "**isolated system**" is a purely abstract notion, as it cannot have any exchange of **matter, energy or information**. This situation condemns it moreover to internal **entropic** annihilation

For another angle of view, metapatterns have a dynamical character and are frequently recurrent. This is as obvious in **history** as in music, for instance (A. GOPPOLD, 2000, p. 110-11)

2101

METAPHOR¹⁾ - 3)

"A linguistic form which is used to acquire and communicate **knowledge** through a transfer of **meaning**" (J.van GIGCH, 1993, p.45).

Etymologically, a "meta-phor" is a carrying over device. Accordingly, a metaphor is a transfer of the **meaning** of a word, usually from concrete to abstract, by its inclusion in a unusual **context**.

Example: "the root of the difficulties". Of course, only plants have roots, but the word "root" may be used to describe and convey the more abstract notion of the **basic** origin or the difficulties.

In a more general sense, as expressed by C. MESJASZ: "Metaphors involve the transfer of **information** from a relatively familiar **domain**... to a new and relatively unknown one" (1992, p.1174).

The positive aspect of this transfer is that it frees **creativity** by crossing hitherto blocking **paradigmatic limits**. However, as metaphors create **analogies** within the mind, they should be taken and used with much care because they may perfectly well generate **false analogies**, or at least overextended ones. Propaganda, for example, makes an enormous use of unsound metaphors.

MESJASZ observes rightly that while: "... metaphors and **analogies** (are) inherent parts of the **language**... (their) applications... can have a strongly normative character, frequently based on various ideological assumptions" (Ibid).

Metaphors should be thus carefully scrutinized, especially in systemics and cybernetics, whose **models** could easily be weakened, or even perverted, by their imprudent use. A satisfactory **process** of elaboration should lead from metaphor through confirmed **analogy**, to **homomorphic models** of **concrete systems** or **situations** and, when possible to general **isomorphic** and **transdisciplinarian** more abstract **models**.

Quoting G. MORGAN (1980), J.van GIGCH writes: "Metaphors can be used "to understand one **element** of experience in terms of another... They provide a **framework** to structure **perceptions**... (and they have) important implications for the **process** of theory construction" (quoted Ibid, 1993).

According to H. MALTA MACEDO: "A metaphor, although sharing properties of both **component** units, conveys a new specific **meaning** rooted in the fused total areas of transected, enhanced attributes" (1992, p.677).

Metaphors offer interesting **heuristic** openings, but then only if they are correctly critized and evaluated, a point made by D. and G.A. MIRHAM who insist on the necessity to seek confirmation of speculative metaphors, or of their eventual rejection.

They also state that the linguistic scrutiny of the metaphor is an important stage of its critique (1975, p.51).

H. ATLAN expresses the following about the "genetic program", a very apt example of metaphor's limitations and dangers: "The problem with the genetic program is that it is a metaphor, which should not be pushed too far because it leads to practical difficulties and the only way to get around it is to modify the idea of a computer **program** to such a point that almost nothing is left from the metaphor.

"Already from the beginning of molecular biology - and this can be found in every textbook - the so-called genetic **program** was described as a very peculiar **program**, since it needs the products of its reading and execution to be read and executed; or else, that it functions as a self-programming **program**. Additional questions were raised about the **language** in which it is written and it was recog-

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

nized very soon (note: By B. SHANON and D. HOFSTADTER) that the genetic **code** certainly does not constitute a computer **language**, being at most a **lexicon**" (1972).

As a conclusion, it could be said that metaphors are most useful through a consistent critique.

About the use of metaphors in social sciences, and particularly, in **communication**, K. KRIPPENDORFF observed that "most social scientific theories can be shown to have grown out of ordinary folk wisdom" (1993, p. 3). He gives numerous examples. He moreover questions the consequences of this not very conscious phenomenon. Among them he discusses

- communicative **competence**
- communicative authority
- self-authorization in mass **media**
- impoverished communication (specially through **manipulation**)
- surrender of cognitive authority

As a conclusion, systemists should always carefully scrutinize metaphor-tainted **concepts** and **models**.

→ **Frame of reference; Information; Map territory relation; Model accuracy; Model as a system; Symbolic processing**

2102

METAPHOR (Organismic)^{3) - 4)}

A metaphor "that represents the **organization** as an **open system** seeking to adapt to the turbulent **environment** it is confronting" (M.C. JACKSON, 1992, p.219).

JACKSON comments: "The tendency to treat **organizations** as if they were *organisms* has been especially pronounced among advocates of the systems perspective in **organization theory**" (p.24).

This metaphor is of course interesting, but it does not clarify very much the individual **roles**, as they are or as they could be, nor the **meaning of values and norms in organizations**.

2103

METAPHOR THEORY (Conceptual)¹⁾³⁾

M. DANESI has given steps toward the elaboration of a general theory of metaphors, which amounts to a kind of theory of **abstractions** constructions (M. DANESI, 2001, p. 5-24)

The general idea is about our way to construct embracing **frames of reference** through successive (**meta-**) **levels of abstraction**.

This attempt is somewhat akin to KORZYBSKY's **structural differential**, but also offers new insights.

DANESI starts with a **layering theory** of metaphors, (which is itself a metaphor!), related to PEIRCE's concepts of firstness, secondness and thirdness.

To begin with, DANESI distinguishes various types of metaphors as:

- animal ones, as for ex. "the professor is a snake"; "he is a real hog"; "she is a true pussycat"

- visual ones as for ex. "there is more in it that meets the eye"; "from the viewpoint", "see eye to eye"; develop a "worldview"

At a second level of abstraction more abstract metaphors appear:

- "he is a voracious reader"
- "Darwin is the **father** of modern biology"
- "That idea is not in **vogue** any longer"
- "That theory needs **support**"
- "His views have contemporary **offshoots** or, in a **culture** strongly influenced by markets:
- "That idea just won't **sell**"
- "That's a **worthless** idea"

Finally, DANESI writes about "meta forms", "metaforms", "metasymbols" (p.21) and shows how the use of metaphors provides a synthetic **framework** for the **understanding** of the way human abstract systems are constructed.

He notes that this "basic human tendency to think of abstract concepts iconically and through **association** was already pointed out by Giambattista VICO (1682-1744) the Italian philosopher" (p.8)

→ **Concept; Constructivism; Level; Pragmatism: a systemic view**

2104

METAPHORIC FRAMEWORK¹⁾²⁾⁴⁾

H. BENKING and A. JUDGE observe that the "intellectual product" of international conferences of all kinds "takes the form of complex declarations and programmes"

They consider that "the challenge is to configure the conceptual **elements** into a global comprehensible form. This is necessary to counteract the tendency to generate an **asym-metric** agglomeration of elements" (1994)

While this is obvious, it is also obvious that the actual form of the post-conference declarations is sometimes a true reflection of contradictory intentions and interests of the participants...and even of the muddled thinking of some of them.

The authors add: "In addition to its mnemonic function, a metaphoric framework can then highlight the possible missing elements as well as suggesting ways of understanding interesting functional relationships between such elements" (Ibid)

This is again obvious, but **transparency** may be in some cases ignored by some who want to better dissimulate covert intentions. Moreover, the selection of the metaphoric framework itself could easily become the source (or the pretext!) of endless and inconclusive debate

2105

METAPHORS (Classes of)²⁾

H. BENKING and A. JUDGE write: "There is a need to distinguish classes of metaphors offering different advantages and disadvantages. Typically they would include: geometric **forms** (cube, sphere, polyhedra in general), artificial forms (townscapes, house, room), natural forms (landscape, trees, etc.), systemic **structures** (highway systems, pathways, flow systems), dynamic systems (atomic, molecular, planetary, galactic systems), traditional **symbol** systems (mandalas, sand paintings, etc.)" (1994)

In fact, what the authors call metaphors can in most cases be also considered as **models**.

To their listing an important addendum would be **topological graphs**, **matrixes** and mathematical curves (for ex. exponential, asymptotic, logistic, gaussian)

The authors add: "Of special interest are those **sets** of metaphors which permit **inter-transformation** with minimal loss of conceptual integrity (in terms of maintaining **relationships** between **data** referents) (Ibid)

And: "With **information** beyond a certain degree of **complexity**, it is questionable whether any single metaphor is adequate as an **inter-face** for adequate comprehension. This is best exemplified by the wave/particle metaphors used to comprehend fundamental physical systems" (Ibid)

Moreover: "It is equally desirable to understand the use of metaphors in terms of the alternation between perspectives which provide a sense of depth that would otherwise be unavailable. Such "depth" is distinct from that obtainable from any 3-D metaphor which although it offers depth, is cognitively not as significant as that offered from the cognitive integration of two contrasting metaphors. Such "depth" is only achievable by alternation between metaphorical interfaces (as the wave/particle example suggests)" (Ibid)

As an interesting tool, the authors also propose the creation of a "library of metaphors"

2106

METAPHORS (Systemic and cybernetic)^{1) - 3)}

"General **constructs** which can be associated with general tools of thought for organizing **knowledge**" (P. PATON, 1999, p. 150)

"Examples of systemic metaphors include: **machine**, **text**, **organism** and **society**" (Ibid)

Systemic metaphors should of course be used in a guarded way because of possible abuses of **analogies** that can easily lead to dubious interpretations and statements.

They may however reveal structural and/or functional characteristics of entities through researching apparent or real **similarities** between entities of different natures or at different levels. A good example is J. MILLER's **cross level research in living systems from cells to societies**.

D. GREGORY observes: "What is important about perceiving the metaphors that we use is that different metaphors lead to different axioms, problems and **goals**: they constrain our thinking as much as they allow it to proceed in particular directions. They are both vantage points and prisons. They simultaneously support both great clarity and mind-binding impenetrability" (1993, p.69).

Consequently, a census of systemic metaphors could be very needed to create a clearer conscience of their own uses of **language** by systemists and cyberneticists.

Originally, systemic metaphors were basically **organismic**, while cybernetic ones were **mechanicist**.

As to the first ones, R.M. SNOW observes: "... the **organismic** metaphor is widely used in both **functionalist** and **structuralist** writings as well as in works of **general systems theory**. Functionalists portray systems as pursuing **goals** within "**environmental**" **constraints**. They also discuss the **dynamics** of social **groups** in terms of "**development**". Structuralists have coined an **organismic** term of their own: "genesis", used to label systemic **changes** of great magnitude. It is often used together with the concepts of "**development**" and "**evolution**" (1993, p.142).

Cybernetic metaphors, through the concepts of **feedback**, **regulation** and **control**, were at the beginning basically translated from engineering. This provoked a strong resistance from social scientists, but was more or less tolerated by biologists, who were already acquainted with the concepts of **homeostasis** and **regulation**. Later on, cybernetics diverged in two directions, with new and generally more accepted metaphors. First, M. MARUYAMA introduced the **deviation-amplification model** of "**development**", somehow related to the **organismic** metaphor. Next, H.von FOERSTER, H. MATURANA and F. VARELA introduced **eigen behavior**, **organizational closure** and the **observer-actor**, all of which are non-mechanicist.

SNOW also observes the existence of what could be called the **digital** metaphor: "... **communication** theorists have built their central scheme around opposing pairs: sender versus receiver and **message** versus **noise**. **General systems models** based on **binary logics** used to simulate a wide variety of **behaviors**" (p.143).

More formal metaphors appeared from the seventies on: "catastrophes", "fractals", "fuzziness" and "chaos", for instance. These very

terms imply a metaphoric bias, which may – and has – lead to abuse.

→ **Glue**

2107

META-POLICY⁴⁾

The **management** of **complex systems** in order to obtain the best possible **long-term** results.

This kind of **management** "seeks simplicity, but distrusts it" (A. RAPOPORT).

Its principal weapons are **meta-models** and **meta-tools**. It tries to avoid **short-time** expediency, mistrust **short-term** extrapolations and **sub-optimization** (brought about by unilateral **maximization**).

2108

METAPOPULATION²⁾

A variable global population composed of **patches** shifting and fluctuating in time.

L. PITELKA et al., who use the concept in vegetal **ecology**, write that some "local **extinctions** can be balanced by **colonizations**" (1997, p.469).

However an excessive **fragmentation** into very reduced populations widely separated may lead to total **extinction** or at least **extinction** of some varieties.

There are also metapopulations in animal species and even possibly in human trades and cultural traits.

2109

META-SKILLS (Systemic)²⁾

The skills obtained by the use of systemic and cybernetic **concepts** and **models**.

The aim of **General Systems** and **Cybernetic methodology** is the shaping or generalization of **concepts** and **models**, which appear recurrently in various or many specialized disciplines.

The main specific skills obtained by their use are an enhanced capacity to understand the basics of other disciplines, the capacity to integrate one's own **action** within professionally or culturally **heterogeneous groups**, more facility to tackle complex **situations**, by obtaining an integrated view of their nature and possible **transformations** through **time**.

2110

METASTABILITY²⁾

The condition of a system which remains stable only in the absence of even a slight **stimulus**.

As observed by E. JANTSCH: "Stability is not a notion which might govern (**human**) **systems** over very long **periods**... Systems of high **complexity** trade **stability** for richness in **adaptability**" (1975, p.62).

Metastability manifests a system's readiness to adopt alternate states of **stability**. It is a border condition, depending on merely marginal **stability** of the system's **environment**, which should remain "benign", to use R.N. ADAMS word (1988, p.24).

Such a condition exists in a quite widespread variety of systems. The **stimulus** is generally the introduction into the system of some "seed" or "nucleus". Once this occurs, the **dynamics** of the system suddenly changes, through a kind of flip-over (or "**catastrophe**").

This **phenomenon** is well known in physics (condensation or crystallization of supersaturated solutions); in epidemics (explosive pandemics); in economics (market reversals) and in societies (sudden surge or reversals in beliefs or collective **behaviors**).

The basic condition for metastability seems to be a relative **independence** of the **elements** of the system. See: "**Systems (Composite)**".

A. LOTKA stated: "Dynamically, the characteristic of a metastable **equilibrium** is that the thermodynamic potential of the system, though a minimum, is not an absolute minimum" (1956, p. 151).

R. FIVAZ adds (quoting G. NICOLIS and I. PRIGOGINE -1977, as well as R. SWENSON – 1989, and J. WICKEN – 1989b): "In metastability **regime**, **transitions** from simple **structures** to more complex **structures** take place only if the **rate** of **entropy** production is increased. This theorem is central in the theory of spontaneous **complexification** and establishes the DARWIN-like relationship between **structure** and **function**: only **structures** with a superior functional **time rate** are selected. The corollary is that, in the long run, systems will acquire the best performing **structures** that their couplings can possibly support" (1991, p.24-25).

R. FIVAZ also emphasizes that metastability **transitions** are fast and global (p.21).

These views seem related to St KAUFFMAN's "**edge of chaos**" (1993), where the maximal **instability** results of **dissipative structuration** at thermodynamic **instability thresholds** leading to **bifurcations**, conducive in turn to higher **levels** of **entropy** production, somehow compensated by increased **complexity**.

2111

METASYSTEM^{1) – 2)}

"A system over and above a system of lower logical **order**" (J.van GIGCH, 1986a, p.3) (After St.BEER).

J.van GIGCH comments: "...and therefore capable of deciding propositions, discussing **criteria**, or exercising **regulations** for systems that are themselves logically incapable of such **decisions** and discussions, or of self **regulation** (because the metalogic is inaccessible to the system's logic, or the **metalanguage** is capable of statements inexpressible in the system's **language**)" (Ibid).

¹⁾general information

²⁾methodology or model

³⁾epistemology, ontology and semantics

⁴⁾human sciences

⁵⁾discipline oriented

A metasystem is a system of second **order**, i.e. describing "the **change** from one system to another in the delimited **class**... by a replacement procedure that is **invariant** with respect to the **support** employed" (1991, p.62). Such a procedure can be applied **recursively** and produce metasystems of second order, and so on.

M. BUNGE enounces the following axioms: "Every conceptual and every **symbolic system** of human **knowledge**, is or can be **embedded** in a wider system of the same kind;

"Every **concrete system**, save for the **universe** as a whole, can be included in a larger **environment** with which it exchanges **matter** or **energy**" (1993, p.215).

Let us observe anyhow that the "**universe**" is in fact the abstract – and hypothetical – keystone for the whole logical cathedral. Generally, man is a constructor of metasystems, many times unwittingly, as the *motives* to construct **controls**, **regulators** or **rules** are not included in the same.

2112

METASYSTEM PARADIGM²⁾ – 3)

"...A form of **metamodeling** which is used to conceptualize and study **decision-making** in **complex hierarchical systems** at several **levels of recursion**" (J.van GIGCH, 1986a, p.3).

van GIGCH explains: "... the **organization** is conceptualized as a **hierarchy** of **control** systems. A **control** system consists of a **controller** (CR) which exercises control over a controlled system (CS) which in turn, interacts with an **environment** (E). At the same time, there exists another **controller** – a **metacontroller** (MCR) – which exercises control over the **control** system C, made up of CR, CE, and E. The addition of a meta-metacontroller (MCR') defines **control** at the second **level of recursion** where MCR' exercises **control** over the **control** system C' made up of CR', and CS', and E'. It is to be noted that MCR from the first **level of recursion** becomes CR' at the second. Similarly, the control system C becomes CS'. **Environment** E and E' are not necessarily equivalent or **isomorphic**" (1986b, p.69).

2113

METASYSTEM PARADIGM: Epistemological status³⁾

J.van GIGCH clarifies as follows the status of the epistemological questions which the meta-system paradigm attempts to answer

"Epistemological questions for which the metasystem paradigm does not hold answers

1. The question of problem definition: How should the problem be defined: "In everything there is everything"
2. The problem of **coherence** or of **holism**: How are the **boundaries** of the irreducible **whole** defined?

3. The question of **complexity** and solvability: Reality is complex but complex **models** cannot be solved

4. The question of 'idealism' vs 'realism': The idealist propounds impractical solutions which consider the **whole**; the realist present nearby solutions which are practical but nearsighted.

"Epistemological questions for which the metasystem paradigm holds answers

1. Problem of **optimization** and **suboptimization**: Can we really optimize? What is **centralization** and decentralization?
2. Principle of **invariance**: Is there **isomorphism** between systems **levels**?
3. The **ontological** question: Do **hierarchies** really exist?
4. The guarantee of **truth**: How do we guarantee **truth** or the **validity** of our solution?
5. The question of **observability** and of **control**: Interplay between **observer/designer**, **description** and prescription. Role of **purpose** in **teleogenic** systems". (pers. commun.)

2114

METASYSTEM TRANSITION THEORY¹⁾ – 2)

A general theory of evolutionary **change**.

MST has been proposed by the Principia Cybernetica Group (F. HEYLIGHEN, C. JOSLYN and V. TURCHIN).

This is a theory about "the primary act of **evolution**, the free and spontaneous **emergence** of higher **levels of organization and control**...

"The **phenomena** explained in terms of metasystem transitions include the origins of life, of sexual reproduction, of multi-cellular **organisms**, of neural **organisms** capable of coordinated **action** and **learning**, of thought and **language**, and of human society and industry. In the future we predict the development of global human society and human meta- or super-beings, which preserve the cybernetic **organization** of human minds through direct human-machine and human-human **connections**" (1992a, p.509).

More than a theory, this is a general hypothesis that should be researched more deeply. This is the announced goal of the Principia Cybernetica Group.

Ch. FRANÇOIS proposes an "Integrative view of Meta-System Transition" in relation to various systemic evolutive **models** as **chaos**, **deviation-amplification processes**, **dissipative structuration**, **disymmetries**, **hypercycles**, **organizational closure**, etc... He applies the concept to the general **evolution** of humanity, including the present trend toward world **integration**. (1995, p.173-79).

→ **System (Meta-) Transition**

2115

METATHEORY OF SYSTEMS RESEARCH³⁾

"The general principles of constructing **knowledge** concerning the system **objects**"... or "a theory of systems theories" (I.V. BLAUBERG et al, 1977, p.195).

P. CAWS wrote: "Systems theory is a way of looking at systems, but theories themselves are also systems. They are composite **wholes** whose **parts** are propositions, related to one another in complex and dynamic ways...

"The chief function of theories,... is to anticipate the **behavior** of physical systems. If in theory the device blows up, in practice it had better not be built that way" (1968, p.3).

A theory aims at being **isomorphic** in some respect with some **concrete systems**. It can work if: "... its function is *to be* adequate to the world."

However : "Questions about the adequacy of scientific theories, like questions about their logical **structure**, their origins, their usefulness, etc., are *metascientific* questions; and a number of metascientific disciplines – the philosophy of science, the history of science, the sociology of science – have grown to deal with them. These disciplines, however, are not simply descriptive, they are theoretical to, or better *metatheoretical* – ways of looking at scientific theory, or ways of looking at ways of looking at things" (p.4).

In this way, the concept of an entity functioning as a **whole** appeared in various disciplines and we have thus an interpretation of the **cell** as a system, of the **brain**, of the individual, of the business enterprise, or a **culture** in the anthropological sense as systems. In each case the corresponding systemic theory seeks and finds some specific **isomorphies** between the constructed **model** and the **concrete system**.

But we may advance further: *isomorphies can be discovered between models constructed in different disciplines*. Systems of different kind tend to be, each in their way and at their **level**, **autopoietic**, **heterogeneous**, **hierarchical**, etc... It is thus possible to construct a general systemic **model** of any of these characteristics and to study its necessary **organization**. Why, for example, must all systems be **heterogeneous**? What has **heterogeneity** to see with **wholeness**? Etc...

Or to go back to CAWS and to BLAUBERG, SADOVSKY and YUDIN, we may be able to construct a theory of systems theory, principally by studying the **isomorphies** between **models** and their deeper reasons.

The conclusions thus reached at can then be applied very generally to any **object** amenable to a systemic **model**.

It is still possible to go farther and to try understand how and why our **brain** is able to construct this type of general **modelization** and how and why we are able to reach **consensus** about this **process**.

2116

META-TOOLS²⁾

The collection of systemic and cybernetic devices and **models** that can be used to tackle complex **situations**.

Meta-tools are specifically directed to the **integrative** and the **nonlinear processes** that take place in multi-connected **networks** within **complex systems** or in their **interrelations** with their **environment**.

2117

META-UNCERTAINTY³⁾

"The uncertainty about the accuracy of estimating the uncertainty of a **class of events**" (K. KRIPPENDORFF, 1986, p.49).

KRIPPENDORFF writes: "In **information theory**, meta-uncertainty is calculated on the probability **distribution** of possible samples drawn at **random** from a hypothetical **universe** having the same uncertainty or **entropy** as the sample actually observed... By the **law of large numbers**, meta-uncertainty decreases with increasing number of **observations**" (ibid).

2118

METHOD²⁾

A **procedure** that can be regularly applied to solve some kind of **problems** or to manage some types of **issues**.

According to T. KOTARBINSKI, "a method always implies a way of acting" (1995, p.26). However "some people define a method as an intended way of acting, or a way of acting of which the **agent** is conscious" (p.27).

One should say that, as methods seem proper to human beings, their uses are always "intended". It seems however possible that a method can be applied in a non-conscious, or in a sub-conscious way, as for instance when driving a car.

KOTARBINSKI relates methods - and **methodology** - to the uses of practical skills (ibid).

→ **Program; Routine**

2119

METHOD (DESCARTES discourse on)³⁾

In this famed piece of scientific philosophy, DESCARTES (1596-1650) enounces as follows the four "precepts" to "conduct one's reason" in a correct way:

"The first was never to accept anything for true which I did not clearly know to be such; that is to say, to avoid carefully precipitancy and prejudice, and to comprise nothing more in my judgment than what was presented to my mind so clearly and distinctly as to exclude all ground of doubt.

"The second is to divide each of the difficulties under examination into as many parts as possible, and as might be necessary for its adequate solution.

"The third, to conduct my thoughts in such order that by commencing with **objects** the simplest and easiest to know, I might ascent by little and little, and, as it where, step by step, to the **knowledge** of the more complex; as-signing in thought a certain order even to those **objects** which in their own nature do not stand in a relation of antecedence and sequence.

"And the last, in every case to make enumerations so complete, and reviews so general, that I might be assured that nothing was omitted" (S. CUMMINS & R.L. LINSOTT's translation, 1947, p.175-6).

These concepts have dominated scientific research for more than three centuries and led to considerable progress, through an ever increasing specialization.

However, the following caveats should be taken into account:

- DESCARTES' concept of evidence is subjective and implicitly based on an **ontological** absolute. This remains largely true even when the "evidence" is inter-subjectively accepted through a wide **consensus**.
- While "dividing the difficulties" may indeed be useful in many cases, it easily leads altogether to severing **links** and **interactions**, i.e. destroy the very nature of **complex systems**.
- While DESCARTES third precept about climbing back toward "the more complex" is sound, he does not give any **method** to re-construct the severed **links**.
- His "complete enumerations and general reviews" can never give a complete security that "nothing has been omitted", since he gives no **criterion** for **evaluation** on this supposed completeness.

Even if the historical usefulness of Cartesian method has been massively demonstrated, the above objections explain why **reductionism** is insufficient for the satisfactory study of **complex systems**.

2120

METHOD (Scientific) and CHAOS^{2) - 3)}

J. CRUTCHFIELD et al point out that: "The existence of **chaos** affects the scientific method itself. The classical approach to verifying a theory is to make **predictions** and test them against experimental **data**. If the **phenomena** are **chaotic**, however, **long-term predictions** are intrinsically impossible. This has to be taken into account in judging the merits of a theory. The **process** of verifying a theory thus becomes a much more delicate operation, relying on statistical and geometric properties rather than on detailed prediction" (1989, p.48).

It is by now clear that only the most simple systems - those whose **dynamics** involves only two, or maximally in some cases three independent **initial conditions** - can be studied by using the traditional method, which should,

from now on, be considered merely as a specific aspect of a quite more general method to be applied to complex systems whose determinism is merely global and not narrowly constraining. The principles of this new method are only starting to emerge now.

See in this respect the insightful comments of the quoted authors (p.48-49).

2121

METHOD (Systemic)^{2) - 3)}

J.L. LE MOIGNE, after a sharp critique of the famous Cartesian four principles (see **Method (discourse on the)** enounces in a somewhat jocular way his own four precepts for a "new discourse on the method", in this case, the systemic method:

"The precept of **relevance**: Acknowledge the fact that any **object** that we consider is defined in accordance to the explicit or implicit intentions of the **model** builder. Never refrain to doubt our definition if our **perception** of the **object** becomes modified in relation to a modification of our intention.

"The precept of globalism: Always consider the **object** whose **knowledge** we seek as an immerged **part**, active within a greater **whole**. Perceive it first globally, in its functional **relation** with its **environment**, without bothering too much to establish an accurate **image** of its internal **structure**, whose existence and uniqueness should never be taken for granted.

"The teleological precept: Interpret the **object**, not in itself, but better by its **behavior**, without seeking an a priori explanation of such **behavior** by some law supposedly implied in some **structure**. Conversely, try to understand this **behavior** and the **resources** that it puts to use in relation to the "project" that the **model** builder adscribes to the **object**. Take the identification of these hypothesized projects as a rational intellectual act, admitting that their demonstration shall very seldom be possible.

"The principle of **aggregation**: Acknowledge that any **representation** is a simplification, not by some omission of the **model** builder but in a deliberate way. Consequently, seek some recipes to guide the **selection** of **aggregates** to be considered as relevant, and exclude the illusory **objectivity** of an exhaustive census of the **elements** to be taken into account" (1990, p.23).

These "precepts" are, of course, quite at variance with those of traditional **reductionism**, which count with a long history of successful results in many specific specialized fields. They do not replace ordinary scientific method, but complement it for the modeling of **complex systems** taken as **wholes**.

Apparently, what LE MOIGNE calls "method" - probably in traditional reference to DESCARTES - is called "methodology" by other authors, for whom a methodology is a *set of methods* of various types (see next heading).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

G. KLIR, for instance, writes: "It is the most fundamental commitment of systems methodology to develop methods for solving genuine systems problems in their natural formulation. Simplifying assumptions, if unavoidable, are introduced carefully, for the **purpose** of making the problem manageable and, yet, distort it as little as possible. The methodological tools for dealing with a problem is of secondary importance; they are chosen in such a way as to best fit the problem, rather than the other way around. Moreover, the tools need not be only mathematical in nature. They may consist of a combination of mathematical, computational, **heuristic**, experimental, or any other desirable methodological traits" (1993, p.39).

In any case, systemic method, (or methodology?) properly, is not referred to a specific trade. It is based on the search for coherent **wholes** clearly distinguished from each other and from their general surroundings. The characteristic methods to study these systems would be the use of structural and functional **isomorphisms** with the help of specific systemic and cybernetic concepts as for example **autopoiesis**, **regulation**, **structural dissipation**, etc.

2122

METHODOLOGICAL PLURALISM ²⁾

Many discussions between authors proposing different **methodologies** for the study of **complex systems** led to some confusion about supposedly contradictory claims.

There is even some danger that these controversies could obscure the respective merits of different **approaches**. M. JACKSON, after a careful consideration of various proposals, proposes a definition of the kind of pluralism that is required: "Pluralism needs, as an approach to managing complex problems, to employ a meta-methodology to take maximum advantage of the benefits to be gained from using methodologies premised upon alternative **paradigms** together, and also encourages the combined use of diverse **methods**, **models**, **tools** and techniques, in a theoretically and methodologically informed way, to ensure maximum **flexibility** in an intervention" (2000, p. 387).

A useful collection of papers edited by J.C. MINGERS and A. GILL (1997) also focuses on multimethodology.

Still another pluralistic methodology has been proposed by A. TAKET and L. WHITE, under the name of PANDA (Participating appraisal of needs and the development of action) (1998, p. 153-158)

→ **Conceptual blocking; Experimental frame; Frame of references**

2123

METHODOLOGY ¹⁾ – 3)

Any **set** of principles, procedures, practices and techniques concerned with some scientific discipline.

According to K. KRIPPENDORFF: "The aim of methodology ... is to describe and analyze not the **objects** or the products but the **processes** of scientific inquiry, to investigate the potentialities and limitations of particular techniques, to reveal their presuppositions and **epistemological** consequences, to suggest structural reasons for successes and failures, and to develop, test and offer generalizations about scientific procedures" (1986, p.50).

Methodologies evolve in relation to dominant **paradigms**. For example, until about 100 years, methodologies based on strict **linear determinism** where taken for granted and dominant. Later on, statistical methodologies gained a hold. And more recently, methodologies adapted to the study of **nonlinear complex systems** are emerging.

In any case, even if every discipline has its own methodological requirements, there is a **level** of general scientific methodology (in constant evolution) whose features supersede more specific, but also methodological aspects.

W. ACAR gives two different definitions for methodology, the first one by C. SCHOLZ (1987, p.53): "(Methodology) deals on a **meta-level** with the nature and creation of concepts suitable for the development and implementation of **methods**."

Methods thus viewed would be the actual tools, say, for example mathematical analysis, or MILLER's **cross-level hypothesis**, or case studies in psychology.

Next, ACAR gives his own definition: "The overall world view, **meaning** and **action** system governing research activity is the field of **inquiry**" (1987, p.120).

This definition is closely related to the one ACAR gives of "**paradigm**". But such closeness is debatable, as shown by the opinion forwarded by J.van GIGCH: "We distinguish a **paradigm** from a **methodology** by indicating that a **paradigm** is usually "**content**" or "substance-free" in the sense that it applies to many problems in a **domain** regardless of their specific **content**, whereas a methodology is a problem oriented procedure or approach which incorporates a particular **paradigm**" (1993, p.44).

B. BANATHY gives a more restricted definition, fit for disciplinary practical uses: "... a **set** of coherent, related, and internally consistent **methods** applicable to pursuing disciplined **inquiry**". He adds: "In the scientific **inquiry** of any discipline, methodology is clearly defined and it is to be adhered to rigorously regardless of the problem or area of investigation to which it is applied" (1988, p.27).

This compiler must confess that he remains unable to form a clearly definitive opinion about the precise limits between **paradigm**, methodology, methodologies and **methods**.

2124

METRON ²⁾

"Unit of metrical **information** which supplies one **element** for a **pattern**" (D. McKAY, 1969, p.166).

Mac KAY comments: "Each **element** may be considered to represent one unit of evidence. Metrical **information** gives a **pattern** its weight or **density** – the stuff out of which the **structure** is formed.

"In a scientific **representation**, each metrical unit may be thought of associated with one elementary **event** of the sequence of physical **events** which the **pattern** represents" (Ibid.).

Each metron diminishes the quantitative **randomness** contained in the **variety** of possible **messages**.

Thus, while metrons are indispensable **elements**, only their ordered grouping produces a significant **pattern**. Metrons **interconnections** according to defined **rules**, are constitutive of **logons**.

2125

MILIEU¹⁾⁵⁾

The french word for **environment**, surroundings. This term has now been introduced in english by some authors.

2126

MIND³⁾

No definition!

The New American Heritage Dictionary – for example – gives 11 different definitions of “mind”, some of them quite difficult to compabilize with others. So, none is given here.

Systemists should make up their... mind about the *concept* of “mind”.

J.M. DELGADO, from his neurobiologist's viewpoint, writes: “The mind is an ill defined entity which usually is described as an active **process**. Most definitions indicate what the mind does, but not what it is or when and how it is formed. Basic mental **functions** are related to the reception, interpretation, **storage** and retrieval of both inner and outer **stimuli**. Some of these **functions** involve the **processes** of feeling, thinking, remembering, willing and other **phenomena**.”

“The **brain**, in contrast with the difficulties in defining the mind, is a well identified physical entity which can be seen, touched and weighted”.

Of course, this is impossible to do with a *working brain* within a skull in a living **organism**.

Besides, it is probably not the point. What is important in the **brain**, as the “producer” of “mind” is its **organization** and the **dynamics** of the cerebral **processes**.

The most that can be said about the so-called mind is to describe it as an abstract designation for a **set** of coordinated **brain** activities that can be investigated as physical **phenomena**. S. GROSSBERG, for instance, suggests that: “**Neural networks** that match sensory **inputs** with learned expectations help explain how humans see, hear, learn and recognize **information**” (1995, p.438-49). The mind is thus no concrete “entity” to be sought for.

The subject has also been deeply discussed by M. BUNGE (1979, p.124-185).

2127

MIND (Society of the)²⁾⁴⁾⁵⁾

A **model** of the **brain** as a vast **network** of **elements** (**neurons**) constantly and simultaneously interacting in multiple and varied ways.

This **model** has been elaborated by M. MINSKY (1986). It is closely related to von NEUMANN's initial work on **reliability** in **automata**; to Mc CULLOCH and PITTS's **neuron** model, to ROSENBLATT's **perceptron** (heavily criticized by MINSKY around 1960) and to MINSKY's own early work on a **neural network** model.

Curiously however, MINSKY manages to construct an impressive, but nearly completely abstract model of the “mind” without practically referring himself to nerves, and still less to **neurons**, which one should suppose to be the “agents” he invokes as the basic **elements** whose **interactions** lead to the **emergence** of the “mind” as an organized society.

Quite surprisingly, and except for quotes at the beginning of each chapter - mostly from novelists and philosophers unrelated to the subject - his book does not contain references to works by biologists, physiologists and neurologists. However it contains numerous figures and **graphs** that look like abstracted forms of **neural connections** and **paths** of **interactions**. At first sight, there is thus no incompatibility between his model and neuro-biological research of the last 50 years, of which one may surmise that he has a good knowledge.

The abstract character of his model may have been at least partly motivated by his belief that it would be possible to construct **computers** (made of interconnected and interactive **agents** - in this case electronic; and working in **parallel**), able to mimic higher cerebral and mental functions.

The model could also probably be used to study the “societies of minds”, i.e. interactive cooperative minds, which are a universal feature of human **groups** and in a near future, the massive planetary society of brains that seems to be now in the making.

K. BAUSCH gives an interesting synthesis of many of the foregoing opinions: “Mind emerges from relations among physical entities but is not itself a physical entity. It is an emergent constellation of **patterns** and **processes** generated through the interaction of **neurons** and the general transceiver functions of the **brain** in interaction with the **embedding holographic memory field**” (Glossary, pers. comm., 2002)

→ **Transputer**

2128

MINDBUGS^{1) - 3)}

Mental distortions that affect the ways people understand **situations** and issues.

This term has been recently introduced by J. WARFIELD, who “so far” identified four categories:

“**Mindbugs of Misinterpretation**: those where concepts are misconstrued or misattributed because of faulty interpretation;

“**Mindbugs of Clanthink**: those where concepts are widely perceived to be correct, but which are demonstrably incorrect;

“**Mindbugs of Habit**: those which involve ingrained **behavior**, evinced with essentially no conscious thought;

“**Mindbugs of Error**: just plain mistakes.

“A fifth category that is under consideration has been designed as “Mindbugs of Specific Human Shortcomings” This category is based on the hypothesis that there may be something inherent in people as people that causes mindbugs which can never be corrected” (1995, p.3).

Many of the 25 mindbugs hitherto identified by WARFIELD became manifest after the appearance of systemics and cybernetics. Others, of psychological and sociological origins, are obvious but were never explicitly acknowledged in a systematic way until now.

Some of the mindbugs listed to date:

- Affinity to all-encompassing **dichotomies**
- Indistinguished affinity to unstructured discussion
- Insensitivity to conceptual **scale**
- Misconstruing technology as science (and vice versa)
- Mistaken sense of **similarity**

WARFIELD even proposes a “mentomology”, as the discipline of the study of mindbugs!

For more details, see WARFIELD's reference.

→ **Blindspot**

2129

MINDSCAPES (Epistemological, Meta-types)^{3) - 4)}

The concept of mindscapes has been shaped by M. MARUYAMA from 1979 on (1979, p.13-23).

According to MARUYAMA, individuals as well as **cultures** differ from each other by very variable psychological and mental orientations.

In connection with **constructivist** psychology, sociology and **epistemology**, and with the **consensus** problem, universally present in every domain, MARUYAMA's typology classifies some of the causes of the innumerable difficulties, misunderstandings, and **conflicts** which afflict humanity.

The four basic types described by MARUYAMA are as follows:

- (1) H-type: **homogeneistic**, **hierarchical**, classificational.
- (2) I-type: **heterogeneistic**, isolationistic, **random**.
- (3) S-type: **heterogeinistic**, **interactive**, **homeostatic**.
- (4) G-type: **heterogeneistic**, **interactive**, **morphogenetic**.

MARUYAMA gives numerous examples. According to him:

“Let us keep in mind there are other types, as well as mixtures of types... In any large society or **culture**, it is possible to find all four and many other types in individuals. The types are partly innate and partly learned. Different **cultures** and professions exercise different pressures for or against some types in the **process** of acculturation, socialization, ostracism, marginalization, etc. Individuals also exercise self-selection, internalization, sublimation, attrition,

alienation, repression, **identification**, etc. It is possible for an individual to change his/her type, but there seems to be a critical age, after which it becomes very difficult to change types. There are individual variations in the age limit as well as in the degree of difficulty. Some individuals become fixed in childhood. Others may be able to change much later in life.

"The mindscape theory may appear to be a typology. However, its purpose and use lie in interrelating seemingly separate aspects of human activities such as **organizational structure**, policy formulation, decision **process**, **management method**, architectural **design**, **criteria** of beauty, **choice** of theories, etc. It is relational rather than classificational" (Ibid).

MARUYAMA seems to view himself as belonging to the G-type. He uses his theory as an orientative guideline for non-authoritarian teaching, that should be "**morphogenetic**", i.e. open to **creativity**.

He applied it more recently to "Mindscapes in **management**" (1994), particularly considering the psychological and cultural problems of expatriate executive officers in multinational enterprises.

2130

MINIATURIZATION¹⁾

The evolutive replacement of **components** in systems by smaller ones.

H.T. ODUM observes such an **evolution** in many mechanical and electronic systems. He believes that the same trend exists in biological systems and writes: "Miniaturization provides more **function** for less power and less **space**, ultimately allowing more **function** and **complexity** for the same **resources**" (1971, p.158).

The trend toward miniaturization could gather new impetus through the use of **self-assembling** materials at microscopic level.

Miniaturization will offer a selective advantage to small **components** and **machines**. However, it also will soon or later reach its limits, even in electronics (See: "The end of the line", The Economist, Nr.7923, June 15th., 1995).

2131

MINIMAL PRINCIPLES^{1) - 2)}

J.H. MILSUM found that: "A number of minimal principles, that is, equivalently **optimality** principles, are recognized in physics". Examples offered are FERMAT's Principles of least **time** propagation of light in media of different refractive indices; MAUPERTUIS's Principle of **Least Action**, and the "most general minimal principle of physics called HAMILTON's Principle".

MILSUM proposes "A generalized verbal formulation of such principles ... as follows: The particular solution "selected" by a **process** in a physical system will be that one out of the possible family of solutions, all consistent with given **constraints**, which minimizes a certain "**cost**" (1968, p.46).

MILSUM proceeds with this comment, very basic from a systemic viewpoint: "The major drawback to universal application is that only conservative systems can be so treated" This is a result of "the ubiquity of **dissipative phenomena**" (Ibid).

The validity of any minimal principle is thus conditioned by the existence of **steady-states thermodynamics**, but ceases in **far-from-equilibrium** conditions.

2132

MINIMAX STRATEGY²⁾

An **operation research method** which "computes the maximum risk and then selects the **strategy** which minimizes this" (1968, p.209).

This **strategy** is a result of J.von NEUMANN **minimax** theorem, according to which, between two players "the maximum of one's minimum is the minimum of the other's maximum" (D. RUELE, 1991, p.52).

von NEUMANN demonstrated his theorem in 1928. It became the bedrock of the Theory of **Games**, fully developed by him and Oskar MORGENSTERN in their 1944 book "The Theory of Games and Economic **Behavior**"

2133

MINIMIZATION ALGORITHM (Adaptive)²⁾

An algorithm that schedules different hints for **learning** in a way that achieves a balance among them and with the training **set**.

Y.S. ABU MUSTAFA, who introduces the concept, writes: "The A.M.A. is adaptive in the sense that it constantly evaluates how well the **machine** is satisfying both the hints and the training examples, and continually modifies the adjustable **parameters**"

The term "minimization" "reflects that the **algorithms** is trying to minimize a quantitative measure of the **error** between the current actions of the **machine** and the **behavior** ultimately desired for it" (1995, p.73).

This concept could possibly be extended to the study of **natural learning networks**. Markets, for example, seem to search in an adaptive way for **dynamic equilibrium**.

The difficulty is to understand and interpret the **behavior** of participants in a self-organizing A.M.A.

2134

MINIMUM (Law of)^{1) - 2)}

"The **stability** of the **whole** depends on the least relative resistances of all of its **parts** at any moment of **time**" (A. BOGDANOV, 1980, p.91).

This 1921 proposition by BOGDANOV is only one of many, but it emphasizes the systemic and the dynamic character of the law.

2135

MINUS-ONE EFFECTS₋

→ See hereafter

2136

MINUS-ONE METHOD²⁾

A way to study the **role** of some **part** in a **whole** by removing that part and observe the result in the system as a whole.

This is a very general method that can be applied to any kind of system, whether biological, ecological, social or mechanical.

The minus-one effects are either specific and, or local; or on the contrary destructive. Let us remember that battle that was lost for want of a horse-shoe.

In some cases, a very minor minus-one effect can act as a **trigger** and may have enormous consequences, particularly in **ecosystems**.

2137

MITWELT¹⁾⁽⁴⁾⁽⁵⁾

A german word whose **meaning** is co-world, i.e. the **environment** with which we are interdependent.

The term would usefully replace the "**Umwelt**" concept, at least for **human system**. In fact, most people see our Umwelt merely as the background that humans can exploit and use at their own convenience, feeling as they were "bosses" of nature, in an unlimited way (ECIMOVIĆ, T. et al., 2002, 1.4)

Contrarywise, "Mitwelt" clearly indicates that the **relationship** is reciprocal: people act and react with their specific environment in various distinct way:

- they must adapt to the nature of the environment: there are for example "desert cultures", islands cultures', arctic cultures"
- they must adapt and readapt to the natural variations of their environment
- they receive **feedbacks** from their **action** on the environment and must adapt to the consequences of these feedbacks

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

All this means moreover that the **interdependence** is a dynamic constantly ongoing and ever variable **process**

→ **Co-evolution; Control; Ecosphere; Eco-systems dynamics; Effects (Delayed); Effects (Side); Parasitism; Regulation; Symbiosis; World engine**

2138

MIXING²⁾

The characteristic "... **behavior** of a system such that any particular **configuration** can be reached from any other one" (R. FIVAZ, 1991, p.32).

This seems to be a quite exceptional characteristic in systems.

2139

MODALITY³⁾

A definite **level** in a **classification** of **levels** of **action**.

A theory of modalities has been introduced by H. DOOYEWEERD, as quoted by D.DE RAADT (1992, p.639). There are 15 **levels** in DOOYEWEERD's **classification** (which like any **classification** is debatable), starting from the "harder" to the "softer": numeric, spatial, kinematic, physical, biotic, sensitive, analytic, historic, lingual, social, economic, aesthetic, juridical, ethical and pistic (religious belief).

Starting from DOOYEWEERD's proposal, D.DE RAADT introduces "**multi-modal thinking**", an "essentially **non-reductionistic**" approach, which "assumes that for each of the fifteen modalities there is a corresponding **epistemology** which cannot be supplanted by and is as worthy as the **epistemology** of another modality... In themselves, no single **epistemology** is sufficient for a complete **knowledge** of the universe, but each contributes to a distinct outlook which, when merged with the others, give rise to a multi-modal thinking that discerns an **object** from every modal angle, leading to a coherent and wise **understanding** of the **object**" (Ibid).

Starting from this base, DE RAADT proposes "**multi-modal design**", which, for any system, starts by defining the various modal **levels** of interest, specifies the basic one and leads to an integrative study.

2140

MODE^{2) - 5)}

1. A specified **pattern** of **periodic** or vibratory movement.

Simple **oscillators** have only one mode of **periodicity**.

Modes are related to **frequencies** in **oscillations**.

D. RUELE writes: "If only one mode is excited, we observe **periodic oscillations**. If various modes are excited, the fluid's movement becomes irregular and, when many modes are excited it becomes **turbulent**" (1991, p.71).

In general, **turbulence** implies **chaotic determinism**.

2. The value occurring most frequently in a series of statistical **observations**, or probability **distribution**.

A **distribution** may present two or more very frequent occurrences. It is then called bi- or multi-modal. This may be the case for instance in **Markov chains** or **Markovian systems** and correspond to various preferred **states**, for example in a **population distribution**. This was interestingly developed by W.R. ASHBY (1956, p.166-7 and 225-29).

2141

MODEL^{2) - 3)}

"A **symbolic representation** of a **set** of **objects**, their **relationships** and their allowable motions" (P. DENNING, 1990, p.466).

DENNING explains: "We use models in three principal ways:

"**Description**: we sometimes use a model to describe how a system works. Examples are a blueprint, a **scale** model of a railroad, the equation of motion of a planet, the scientific method, and the software-**design process**.

"**Computation**: We sometimes use a model to guide, to reproduce or to calculate action in the **domain**. Examples are following directions from an inertial guidance system (guiding), a flight simulator (reproducing), or computing a **measurement** (calculating).

"**Prediction**: We sometimes use a model to predict the future **state** of a system with tolerable certainty. Examples are the models that predict the lift of a wing in flight, the position of a star or the future **state** of the weather or the world economy. A model is useful for **prediction** only if the future **state** can be calculated much more rapidly than in real **time**, and only if its users agree that the assumptions about **parameter** values and governing laws will hold at the future **time**."

This author adds: "Models are of interest because of our unavoidable concern to anticipate and prepare for future **action**, and because they make the world seem simpler and more understandable" (p.466).

B. ZEIGLER observes that a model that "could correctly answer every conceivable question about a real system... is not realistically constructable for large **scale** systems. Indeed, we assume that with every large **scale** system there is associated a multitude of models capable of answering only a limited **set** of questions about the real system with any degree of credibility" (1978, p.81).

T.F.H. ALLEN and T.B. STARR use another definition for model: "An intellectual **construct** for organizing experience" (1982, p.273).

J. CASTI puts it as follows: "The scientific answer to a question is a **set of rules**, or as such **rules** are more commonly termed, a model" (1994, p.4). If this is the case, specific models are mere products of more general conceptual **constructs**... or possibly is it the other way around!

ALLEN and STARR also observe: "We generally do not extend our use of the word to include models as approximations of **ontological** reality. We prefer to acknowledge that we do not know what is the **relationship** of models to **ontological** reality" (Ibid).

→ **Ontological skepticism**

2142

MODEL: A semantic muddle³⁾

In her paper on "Models and retroductive inference", M. ESTEP explores "some of the broad **categories** of the concept of "model" in scientific inquiry" (1992, p.585).

She states: "Clearly, some in the systems science **community** would use "**theory**" and "model" as equivalent. Others have taken a more qualified position, that is that models are "embryonic **theories**" and **theories** are "generalized full-term models" (See next heading) (W. ACAR, 1988, p.172).

According to M. ESTEP, however, "All models and **theories** are "abstract" and "concrete" to some degree".

The **distinction** is still quite obscure: it would seem that any first **level** model is a **homomorphic representation** of some "**object**" (with all the **ambiguities** associated with this term). Further on, collections of more or less **isomorphic** models may appear and allow for the construction of more abstract and general models (in a gradation explained by KORZYBSKI through his **structural differential**). A **set** of abstract models, satisfactorily interconnected within a logical and more global **frame**, could indeed be called a **theory**, as defined by M. ESTEP: "A system of statements which are conjectures characterizing **objects**"...

In any case, **theories** are farther away from **objects** than models are, and reflects quite more our basic mental **structures** and **mind-scapes**.

2143

MODEL (Formal System)

→ **Formal System Model**

2144

MODEL (Generic and Concrete)²⁾

J. ARACIL proposes the following distinction between "generic" and "concrete" model, in order "to clarify some **ambiguity** in the ordinary use of the term model":

"When one speaks currently about models there is some vagueness that is convenient to analyze... On the one hand, one speaks of a model without specifying the numerical values of the **parameters**. In this case we use the term "model" with the meaning of "generic model M". Giving values to the parameters we have a "concrete model C". This is the second meaning of the word model" (1979, p.245).

One of the most demanding challenge to be met by systems science, is to produce generic models which can in turn be used as **matrixes** of concrete models for practical applications.

ARACIL's generalization of FORRESTER's **systems dynamics** by use of **attractors** in order to generate qualitative **bifurcations** in the **modeling process** is certainly an important step toward this goal.

2145

MODEL (Implicit)

→ Knowledge (Implicit)

2146

MODEL (Observer's)³⁾

Any model is necessarily an observer's model. Only **living systems** construct models, as a device for **survival** and only humans construct very intricate models. G.A. & D. MIRHAM make the point: "**Modelling** is the very activity of Nature by which **survival** of Life on Earth is accomplished and assured" (1978, p.134).

R HARDEN states:

"From the prospective of the observer a model might be described as operating in one of two distinct ways:

1) The model may be held to represent or convey a "objective" **state** of affairs (e.g., as the model engine is held to "point at" a real locomotive or the model of DNA is sometimes described as reflecting the genetic **code**). As such, any one model will be understood as true or false if "neutrally" conveying a picture of such "reality".

2) The model might be described as enabling the orchestration of diverse viewpoints, in a **process** that brings forth some **consensually** accepted version of reality for a **community** of observers" (1990, p.291).

The **consensual** model does not negate the existence "out there" of "reality". It only states that this reality is "veiled" (to use B. d'ESPAGNAT's very apt term, 1985), because of our **physiological limits to perceptions** (sensorial and neurological), as observers.

We may admit its validity if we admit a sufficient **convergence** in our own personal ways to perceive and to obtain internal **representations** of some **situation**.

The "engine-type" model could be called hard, because **consensus** is so easy and generally stable (as it refers to man-made or quite common natural "**objects**"), that its existence is not even perceived.

The **consensus** model is a soft one, because it refers to complex **situations** whose observation produces easily ambiguous evaluations.

In any case "we communicate only through models" (G. BATESON). So is it also when we communicate, whatever we want to achieve.

2147

MODEL (Predictive)²⁾

A model whose **dynamic** features lead to, or aim at **forecasting**.

Predictive models are the first condition for the institution of **anticipatory behavior** through **feed-forward** (R. ROSEN, 1991, p.543-4).

ROSEN observes that even biological **organisms** seem to possess some nonconscious **behavioral** traits akin to predictive models, based on the **present observation** or registration of some sequence of **events** that can be interpreted as **early warnings** of future **events**: A deciduous tree sheds its leaves not *because* the winter is coming, but because it registered the recent **trend** of the days to shorten. In such cases, some very general hereditary genetic **trigger** must be present.

ROSEN is in fact quite careful and states: "*In any law governing a natural system, it is forbidden to allow present change of states to depend upon future states*" (p.545, italics his).

See "**teleological explanations**" and "**System (Anticipatory)**".

2148

MODEL (Prescriptive)²⁾

A model that can be used "to prescribe **operations** by which a conceived man-made **object** can be built" (G. KLIR, 1991, p.84).

KLIR states that: "The construction of prescriptive models... is usually referred to as **systems design**" (p.84). This is true, but unfortunate, because this bonafide engineering terminology has been extended to the **design of human systems** and, in not a few cases, contaminated this latter endeavor with restrictive **mechanistic** views.

KLIR explains in a detailed way the two principal stages of the construction of a prescriptive model:

"The aim of the first stage is to formulate the **design** problem on the basis of the conceived **object** to be designed...

"The second stage... consists in constructing a system that implements the required **relations** in terms of the interpreted systems representing the chosen technological primitives and which satisfies the required objective **criteria** and **constraints**" (p.84-5).

A good example of such a **process** would be the progression from the general idea of a new type of car, to the precise blueprints, the planning of retooling, adaptation of the production line and generally related organizational conditions.

2149

MODEL – REGULATOR IDENTITY (Law of requisite)^{2) – 3)}

"Any **regulator** that is maximally both successful and simple must be **isomorphic** with the system being regulated" (R.C. CONANT and W.R. ASHBY, 1970, p.89).

The authors made various interesting comments:

1) Models can be unnecessarily complex.

2) The search for the best **regulator** is essentially a search among the **mappings** from S into R.

3) The proof of the theorem avoids all mentions of **inputs** (an aspect correlated to the **autopoiesis** concept).

4) A **time-varying** model could be needed if the **regulation** is to be **time-varying**.

5) To those who study the **brain**, the theorem founds a "theoretical neurology": "There can no longer be question about *whether* the **brain** models its **environment**: it must" (p.96-97).

Another interesting line should be looking for social regulators (**Values? Norms?**), their degree of **isomorphy** to the social system and their eventual **time-variance**.

2150

MODEL (Retrodictive)²⁾

A model whose use allows the rediscovery of past **states** of the system, with a reasonable degree of **reliability**.

A good retrodictive model, just as a predictive one, depends on the existence of a reliable **knowledge** of the **dynamics** of the system and its **environmental** conditions, normally to be obtained by **inference** from sufficient **data** during a sufficient lapse of **time**. (But, how does one makes sure of what is "sufficient"?).

All in all, retrodiction supposes a well defined basic **deterministic** hypothesis. If the system is **ergodic**, or still worse, **chaotic**, precise retrodiction is impossible.

2151

MODEL (State determined)²⁾

"A model whose future states may be ascertained solely from **information** regarding past **states**" (T.F.H. ALLEN & T.B. STARR, 1982, p.278).

2152

MODEL (Structure of a)²⁾

The **set** of the model's "**components**

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

D. MEADOWS et al. thus describe in fact, the **structure** of a **computer model**. They comment: "... one should be careful to distinguish, when discussing a model, whether or not one is talking about the **structure** of the model or that of the real system" (Ibid).

... That is, if one is mentally prepared to perceive the difference.

2153

MODEL (Symbolic system)¹⁾²⁾

"The description of a conceptual system model (CSM) in a natural or formal **language**" (E. VACCARI & M. D'AMATO, 2000, p. 170)

"A symbolic system model is a **representation** which involves what is represented, the representation and the **modellers** i.e. the user of the representation" (Ibid)

The real problem is of course the representation one.

The authors discuss the computational approach and the biomimetic approach, through "**animats**" (artificial animal-like robots). Here, the question mark is: up to which point do we understand living beings **behavior**- and especially intelligent behavior- and reproduce it in "**animats**".

2154

MODEL ACCURACY²⁾

H.C. GAUCH writes: "Many researchers believe that a model can be no more accurate than the **data** it uses. But is this so? The answer depends on three matters: the precise question being asked of the model; the **design** of the experiment and the quantity and accuracy of the available **data**".

GAUCH gives the example of the MENDEL genetic experiences: "When he combined his **data** from all seven experiments, he found a ratio of 2,98:1 for the dominant and recessive traits. He modeled this as a 3:1 ratio, which also explained and predicted other experimental results" (1993, p.468). GAUCH concludes that "a model can be more accurate than the **data** used to build it because it amplifies hidden **patterns** and discards unwanted **noise**".

This is a very interesting feature, quite important for systemics. It should however be taken with care: discarding "unwanted" **noise** could lead to fudging.

2155

MODEL AND THEORY^{2) - 3)}

M. SIRGY and W. ACAR debate in the following terms the differences of "model" and "theory".

SIRGY writes (1988, p. 171): "A model is a conceptual tool that postulates a **set of relationships** between concepts for the main purpose of controlling a given **phenomenon** from which prediction serves the controlling **function**. A theory on the other hand, is a concep-

tual tool that postulates a set of **relationships** between/among concepts for the main purpose of explaining a given **phenomenon** from which prediction falls out the explanatory **function**".

According to SIRGY, basic scientists tend to use theories more than models. They are more interested in explanation than in **control**, while applied scientists more readily apply models for the opposite reason.

ACAR, on the other hand, describes "theories... as deductive systems" (ACKOFF) and argues that a model is "an embryonic theory", while a theory is generalized full-term model". He understands that the model is embryonic because:

- its **language** is generally borrowed and is seldom tailor-made
- its underlying assumptions may not yet have fully surfaced
- its underlying logic may still be in the making
- its propositions are still being explored and probably have not reached theorem status yet
- not all its implications have yet been understood (1988, p. 173).

Eventually, a much worked out model or a family of models may lead to a theory.

2156

MODEL as a system (The)^{2) - 3)}

P. DENNING writes: "...the model is itself a system that has **variables**, **parameters** and **loops**. It is possible to offer a simple model for a complex **domain**, although we would be surprised if the model were **reliable** in this case" (1990, p.497).

Basically, the model would need to be **isomorphic** to the modeled system. However, as modeling implies simplification, **isomorphies** eliminate too many characteristics, and we are left with **homomorphies**. But, at least, there should be a **minimum of structural and dynamical** correspondance between the system and its model.

In fact, as stated by K. KRIPPENDORFF, a model: "a) embodies a theory of that portion of reality which it claims to represent or b) corresponds to a portion of reality by virtue of an explicit **homomorphism** or **isomorphism** between the model's **parameters** and given **data**" (1986, p.50).

2157

MODEL BUILDING^{2) - 3)}

"A **strategy** by which a conceptual **representation** of a system... is constructed and from which specified outcomes can be determined" (B. BANATHY, 1973, p.87)

This definition by B. BANATHY shows that model building is not a *neutral* activity. Any **representation** is constructed at a specific **hierarchical level**:

1. on the base of **data** collected with a specific intention, hoping that they are correct and adequate.
2. from a specific viewpoint depending on the intention, need or **goal** of the modeler;
3. on the base of the general conceptual **frame of reference** that dominates the mind of the modeler.

The same point has been made by E. JANTSCH: "Model building is essentially a creative or inductive **activity** by which we are building a generalized system out of **elements** of our **consciousness** - though not just of **observations** and rational **knowledge**, as science would have it... Models and myths are inextricably interwoven; what is conceived as a model in one direction becomes a myth in the other, and governs as such the building of new models. So closely interdependent are the two parts of the **feedback process** that we may call them a short-circuit within man's **mind**. If this sounds alarming, it *is* alarming. Of all the traps built into man's cybernetic existence, the model/myth **loop** is the most difficult vicious circle to break out of" (1975, p.191-92).

Other **filters**, not always perceived, do limit the modelizer's **activity**, as shown by St. BEER (1968, p.113-115), M. MARUYAMA (1985, 1994) and other authors:

- **perceptions** are influenced by mental, psychological, cultural and even sometimes physiological limitations or biases;
- when mathematically formalized, the model also depends on the mathematical tools used;
- dynamic **situations** cannot be exclusively represented by **static** models.

More precisely, any model building depends on complex perceptive and mental **processes** whose principal steps are:

1a) **Perception (physiological):**

direct: through our senses

We remain perceptually framed within the **limits** of our physiological capacity to register and assimilate **events**.

indirect: through some **artefact**

Our **artefacts** are supposed to transmit us correctly the **structure** and **processes** that we observe, i.e. without (eventually unknown) deformation produced by the **artefact**.

1b) **Perception (psychological):**

We perceive, at least up to a point, according to our accumulated former training or recordings, and our beliefs.

1c) **Perception (social):**

We tend to conform to what is expected from us. This may easily lead us, for example, to give or receive unreliable testimonies.

2) **Conceptualization:**

Our way to build a mental **representation** of what we perceived depends on our formerly accumulated **knowledge**. Any such **representation** is necessarily constructed in relation to preexisting conceptual **frames of reference** as for example our personal or specific **mathematical knowledge**.

3) Modelization proper:

We construct our models "ad hoc"; having in mind some **purpose**. Thus, we may select a specific model out of various possible ones, because we want to change in some definite way the concrete **process** or system so modeled.

→ **Surrogate world**

2158

MODEL BUILDING (Iterative process in)^{2) - 3)}

Obviously, when a model is put to practical use, its **reliability** is frequently doubtful.

The **modeler** should always be aware of the limits of the model's **validity** and, in consequence, revalidate it frequently: we should remember St. BEER warnings about the "surrogate world we manage" (1973).

Unfortunately, **modelers**, in many cases, do not recognize discrepancies and perturb heavily the *concrete process or system* by taking erroneous **decisions** and stick to them, even against strong evidence.

To avoid this, **modelization** should be iterative, as advocated by St. BEER. This is stated by J. ARACIL as follows: "The **mechanism** underlying the model should be frequently reviewed throughout the modeling **process**. These revisions are made in such a way that the successive models progressively fit in with the modeled **object**. The building up of a model is an **iterative process** where successive theoretical frameworks (normally re-elaborations of former ones) are adapted" (1986, p.243).

As a synthesis, **iterative** construction of models is a cybernetic **process** based on mental **feedback**.

2159

MODEL (Computer)^{3) - 5)}

D. MEADOWS et al describe as follows the main qualities of computer models:

"**Rigour**: The assumptions in computer models must be expressed completely and precisely; no **ambiguities** are possible... (while) Mental models are usually fraught with inconsistencies...

"**Accessibility**: Because all assumptions must be written out in order to communicate them to the computer, critics can examine, assess, and alter computer models. Mental models are unexaminable and uncriticizable; their assumptions are not even entirely clear to the **modellers**.

"**Comprehensiveness**: A computer model can contain much more **information** than any single mental model and can keep track of many more **interrelations** at one time.

"**Logic**: If programmed correctly, the computer can process even a very complicated **set** of assumptions to draw error-free conclusions... Different people may agree completely about a **set** of assumptions and still fight about the conclusions to be drawn from them, if they have only mental models to rely on.

"**Flexibility**: Computer models can test a wide variety of conditions and policies (which is)... much less costly and time consuming than tests in the real world. Different assumptions can be tested more easily and openly than they could be in a single mental model" (1982, p.12-13).

→ Assumptions Analysis

The same authors recognize however that: "Those are *potential* advantages of computer modelling over mental models, but they are by no means always realized. Computer models can become so supercomplex and be expressed in such esoteric jargon that they are less open to critical **evaluation** than mental models. They are not logical **error** free if they contain undetected **errors** in **programming**, typing or interpretation. They are not more comprehensive than mental models if their mathematical properties require the omission of things that non-mathematical people know to be important. They cannot provide easy tests if each run requires several thousand dollars, several days of computer time, six months of **preprogramming** and postprocessing. Computer modelling techniques are also based on deep, unexpressed, technical **paradigmatic** assumptions that are not congruent with mental models and often **constrain** what can be included" (Ibid).

The most important of these **constraints** are probably the need to use **binary logic** in the modelling **process** and the impossibility to take care of *simultaneous change* and thus of the **sensibility** to multiple **initial conditions**, proper to **complex systems**.

As a result, computer modelling, when applied to highly **nonlinear** global problems as in the various **Club of Rome world models**, are prone to many difficult problems and controversial interpretations.

For a critique of "acts of faith that regularly appear in global models" and their computer representation, see the same authors (p.285). Their deeply felt honesty is to be commended.

2160

MODEL (Concept of)^{2) - 3)}

The concept of model has been widely discussed by a number of prominent systemists. Here are some relevant comments:

1. by John WARFIELD (1987, p.229)

"I believe that the word "system" should be reserved for something that is "out there", and the word "model" should be used for whatever human constructions we happen to use as a surrogate for the system. Another advantage of this is that the concept of system always remains open to amendments as more is learned, which is an inherent requirement for scientific advance. And the amendment can be made to the model as required.

"Even the word "model" has been co-opted in effect by people who insist on **underconceptualizing** it to the point where many people interpret the term to be congruent with a set of differential equations or their quantized surrogate, instead of its more general interpretations as a human **construct** applied to describe some **phenomenon**."

2. The same point is made by D. MEADOWS et al: "All human **decisions** are based on generalizations or **abstractions** about the world, or models. Most of these models exist only in people's heads. We call them mental models... complex, shifting and often un verbalized" (1982, p.XIX).

3. For V. TURCHIN a model is basically a "generator of **predictions**": "Informally, a model of a **process** is another **process** which somehow mimics, or simulates, the primary **process**; thus by using a model it becomes possible to know something about the modeled **process** without actually running it, or predict developments before they actually happen" (1993, p.6)... which is all right, provided the model is reasonably accurate... and not too cumbersome.

In other words, let us not confuse some of the numerous specific, and quite restricted type of models with the general concept of model. See in this sense the taxonomy of models established by P. VOLTES BOU and B. WALLISER. (hereafter)

2161

MODEL (Conceptual system)²⁾

"A system perceived as a unit by an **observer** (i.e. the modeller)" (E. VACCARI & H. D'AMATO, 2000, p. 170)

"In general a **modeller** formulates a CSM for some specific **purpose** which determines the aspect (i.e. **selection** of specific significant **attributes** among the infinity of potentially distinguishable ones) or the **process** (i.e. **time function relations** between **attributes**) to conceptualise" (Ibid)

However, there are doubts about the practical use of the CSM when translated to a computational **method**.

The authors state that "basic metaphysical **assumptions** underlying the computational approach are the existence of a **language** of thoughts (FODOR, 1975) and the independence (based on the notion of computational equivalence) of a **cognitive process** performance from the medium carrying on the process itself.

The approach is based on the assumed similarity between the mind and a universal **Turing machine** (NEWELL, SHAW and SIMON, 1958) from which the notion of a physical **symbol** system as an **information** processing device has been derived.

A physical symbol system necessary and sufficient to produce intelligent **behavior** (NEWELL & SIMON, 1976) is a **set** of physical **patterns/discrete symbol** strings and a set of explicit **rules**. The rules can also be coded as **symbolic structures** and they describe how to manipulate the symbols" (ibid)

This seems in fact to be a quite simplistic linear and somehow nearly mechanistic view, very different from the nature of **neuronal net activity** in the brain (i.e. multisimultaneous processing, with **reinforcements**, dampenings, **parallel distributed processing**)

In fact, the classical computational approach evacuates the real **complexity** of modelled systems. This is why conventional **artificial intelligence** does not seem so "intelligent", after all.

2162

MODEL (Continuous or discrete)^{1) - 2)}

Formal or mathematical models can be continuous or discrete. Historically, continuous models based on differential equations have been the accepted **methodology** for modeling in science.

However, since the development of **digital** computing, "discrete models are influencing our conception of real world systems and the role classical mathematical **methods** are to play in modelling them" and: "In many applications of these discrete concepts the availability of theoretical results is replaced by the computational power of **digital computers**" (A.G. BARTO, 1978, or in G. KLIR (ed), 1991.p. 377).

Computers, becoming a kind of experimental laboratory tool, and being **digital**, offer (and require) a new **class** of models, frequently called "**simulations**". This offers at the same time, new **variety** and new **constraints** to **modelization**. BARTO, after a careful discussion, concludes that: "... computational power **alone** is not a substitute for the careful simplification and theoretical generalization that have helped make classical **methods** so fruitful" (p.395).

This clearly is a more polite, but still powerful caveat carrying the same **meaning** as the famous "Garbage in, garbage out".

In any case, both type of models are useful in their own right. Neither, however, tell us the ultimate "**truth**" about reality.

It is also possible that **connection machines** will introduce still another type of models in the future.

→ **Modelization by computer (Limits of)**

2163

MODEL MAKING¹⁾²⁾³⁾

Model making is possibly the most universal and basic mental **activity** of all people. Even superior animals probably elaborate some types of models of their **environment**.

We absolutely need models for our general orientation in life and as a bedrock for **behavior**.

They seem in fact indispensable for our very **survival**.

However a serious reflection about our ways to elaborate models, and even what we mean exactly by "model" is a very recent development. Still now most people make models in a quite naive way.

This is so because scientifically based models need considerable abstract **knowledge**, a fact that would block that basic activity for most people and put them at a loss, or even in danger.

However naive model making frequently leads to dramatically negative results for **communities** as well as for individuals.

A better **understanding** of our model making ability (or incompetence) is one of the most important result of various developments in cybernetics and systemics, among them:

- Autopoiesis (MATURANA y VARELA)
- 2nd Order cybernetics (von FOERSTER)
- Constructivism (von GLASERSFELD)
- Generic Design (WARFIELD)
- Co-participative Design (BANATHY)
- Genetic psychology (PIAGET)
- Gestalt psychology (WERTHEIMER, KOHLER and KOFFKA)
- Metamodeling (van GIGCH)
- Operational research (BLACKETT, ACKOFF)
- Systems dynamics (FORRESTER)

and of course a wide variety of more limited and specific techniques that have also been proposed (See the corresponding entries)

2164

MODEL TRANSFERABILITY^{2) - 3)}

The possibility to generalize a particular model in order to use it in a **variety** of cases.

P.M. ALLEN et al. propose the following – quite systemic – way to construct general models: "Instead of building a model of a particular system (New York, the insurance market in Belgium, the Aleutian ecosystem) in terms of the salient features of the moment, it may be more informative to study generic models (urban systems, markets, interacting **populations**...) and the ways that their constituent **elements** cluster, grow, and structure according to the series of "folds" that their **interactive mechanisms** impart to them, and the **attributes** which emerge for different branches of solutions.

"The study of such evolutionary trees may then show us that New York, Brussels, and other cities correspond to different branches of solution of **similar** models with different **parameter values** and different histories. Only a "transferable" model of this kind can be used predictively on a particular case, since a model built in terms of a particular problem, and calibrated on it, is a purely descriptive **construct** incapable of anticipating **change**. So,... a good model must be a **metamodel**!" (1985, p.76).

... Or at least derived of such a general frame in accordance with the specific situation under study.

And the best **metamodels** are those which retrace **analogies**, **homomorphies** and **isomorphies**.

2165

MODEL VALIDATION

→ **Validation (Model)**

2166

MODELER (Role of the)¹⁾

The role of the modeler should not be merely technical. Even if his/her **models** refer to quite simple **processes**, as for example **queuing**, he/she should at least seek **information** about the system within which **queuing** occurs, as for example in which conditions, when and for which reasons it occurs. Only then may the **model** be really understandable and useful to the **decision maker**.

It must however be conceded that the dialogue between the modeler and the **decision maker** is often awkward. Both could in many case benefit from the **systems approach**.

Modeling also implies **processes** of simplification and **abstraction** that should not remain merely implicit or hidden. In particular, sequential **modeling** in computers implies a certain **concept of causality** which may not take care of real **complexity** resulting from the different **rates** of propagation in **time** of the various interacting **initial conditions**. This problem is quite obvious in FORRESTER's **systems dynamics**.

On the other hand, no modeler is free of biases and, in D. MEADOWS et al.: "One can never be fully aware of all one's biases. But one can be aware that one is unaware and deliberately expose oneself to **situations** in which biases can be discovered (the best way is to 'hang out' with whomever one regards as the enemy). In the presence of all global modelers, the special preferences and phobias of each different global modeler become evident. Giving the thorough agreement that modeling is not and can never be a detached, totally objective **activity**, it would be a refreshing change to see modelers present themselves in person and in print as involved human beings instead of detached, objective mechanics" (1982,

p.278-9). These questions have also been considered, along with the subject of moral responsibility of the modeler, by F. KILE and A. RABEHI in their paper on "The Agenda of the Modeler" (1979, p.18-24).

2167

MODELING and METAMODELING²⁾ - 3)

J van GIGCH emphasizes the important distinction between modeling and metamodeling: "Modeling... implies that the **modeler** "abstracts" properties from things in order to obtain a **representation** of the physical world. It is easy to conceptualize that the **model** stands at a **level of abstraction** higher than the things from which the properties are obtained. The **process of abstraction** can be applied to modeling itself, to obtain a **model** of the modeling **process** which we call a **metamodel**.

"The **metamodel** embodies the properties which are abstracted from all **models** (There is more than one **model**). By metamodeling we imply a **process of design** which is carried out at the **metalevel**, and by which we define how the **process of modeling** (at the **object level of abstraction**), is to be carried out. **METAMODELING** defines the **epistemology** or **design** foundations of modeling. **Design** foundations consist of the reasoning **processes**, guarantees of **truth**, proofs, axioms of validity, or any other logic which underlies a **methodology**.

"Any discussion of modeling must, of necessity, involve metamodeling from which the former evolved" (1992, p.2-3).

If it does not involve it explicitly, it does it in an implicate – if not more or less unconscious – way. This can be risky, because:

- hidden **epistemological** assumptions may be unsound
- they may even be perfectly sound in the **modeler's** view, but not admitted by all **stakeholders**. This may remain unknown if the **metamodel** is not openly discussed.

This is still more important at the **meta-metamodeling level**, where **values** are paramount.

This "ladder" for **validation** is related to **GÖDEL's Theorem**, as shown by Ch. FRANÇOIS (1987), as well as with KORZYBSKI'S **structural differential**.

2168

MODELING (Interpretive Structural)²⁾

A **methodology** "used to enable the participant **group** to develop logical **patterns (structures)** of **relationships** among concepts produced by **Nominal Group Technique**" (J. WARFIELD, 1989, p.2).

The aim of this modeling technique is to limit as much as possible what WARFIELD calls "**Underconceptualization**" which includes remaining stuck in a too limited conceptual

frame; rationalizing so-called "problems" (which are generally "human **constructs** not subject to **observation**"; and shrinking **design** by limiting it to restrictive **contexts** (p.9 -10).

According to WARFIELD: "It is a powerful **learning method**, because it involves disciplined, detailed, examination of **relationships** among factors involved in the complex issue; accompanied by discussion and further clarification".

"The **patterns** produced by the use of this **methodology** can take any **variety** of forms. However a very common form of **pattern** that is produced is called a "**problematique**". This particular **pattern** shows how a **set of problems** all involved in the **issue** are interrelated to each other in an influence **pattern**. Specifically, such a **pattern** shows how a given problem may cause some other problems in the **set** to become worse. **Problematiques** typically contain "cycles"; i.e. **subsets** of problems such that each problem in the **subset** makes every other problem in the **subset** worse. Cycles represent (model) escalating **situations** that may only be susceptible of corrective **action** by working with all the members of the cycle as a **group**, rather than working individually and independently with problems, uninformed by their **interaction**" (1991, p.199).

2169

MODELING (Interpretive structural)

→ Interpretive structural modeling

2170

MODELING RELATION²⁾³⁾

The set of **mappings** in the **model** which reflects characteristics of the modelled **entity**.

This is however a matter of **criteria**, which themselves are used by a model builder in base of his/her **frame of references** (as it is when the model is made) and of his/her more or less adequate **perceptions**.

To appreciate the hidden postulates in models construction, the following viewpoints are specially useful:

- von FOERSTER's critique of the **observer's** intervention in the "observed system"²nd order cybernetics)
- KORZYBSKI's scrutinizing of our ways of **abstraction** through his **structural differential**
- KUHN's work on **changes of paradigms** also considered in other studies about our common use of the Cartesian and the Newtonian paradigms (R. ROSEN, for example)
- MATURANA's studies about our ways of perceptual and mental **relationships** with the "world out there" and the quagmire of our supposed **objectivity**.

Finally, it becomes crystal clear that our models can at most be **homomorphic** (in one or another selected way) to the modelled "**object**".

→ **Constructivism; Isomorphism**

2171

MODELING (Systemic)²⁾

G. KLIR explains the status of systems modeling as follows: "What does it mean to **construct** a system that is a **model** of something else? First, it means that a system, when considered on its own, is not a **model**. It becomes a **model** only in a **relationship** to another system, which usually is referred to as an **original**. Furthermore, this relation is not arbitrary, but it must be a **homomorphic relation**".

"A **homomorphic relation** (or **homomorphism**) between two systems is contingent upon a **function** from relevant entities of one system (the original) onto the corresponding entities of the other system (the modeling system), under which the **relation** among the entities is preserved. If the **function**, which is called a **homomorphic function**, is **bijective**, the relation is preserved completely (we say that the two systems are **isomorphic**); otherwise it is preserved only in a simplified form" (1991, p.77).

A perfect **isomorphism** is conceivable only between two (or more) **models**.

KLIR also states: "Systems models are constructed for the purposes of explanation, **prediction**, and sometimes, **retrodiction**" (p.83).

He also distinguishes between:

- 1) the **postulational approach**, in which "... a hypothetical **generative** system or an **epistemological** higher system is postulated ... (as) a result of the scientist's background **knowledge**, experience, insight, intuition and the like. It is a **frame** for a specific type of **deductive reasoning**" (p.83) and
- 2) the **discovery approach** which is **data-driven**: "That is, **models** are derived by **processes** that discover **patterns** in **data** and utilize them for making inductive **inferences**" (p.84).

KLIR adds: "Neither of the two extremes (and idealized) approaches is actually ever used in its pure form in praxis" (p.84).

2172

MODELIZATION: Analytic or systemic^{2) - 3)}

J.L.LE MOIGNE propose the following comparison between the analytic (i.e., applying a **reductionnist method** of successive decomposition) and the systemic (i.e. using a wholesale approach) modes of modelization (1990, p.9): see table next page

One wonders if the systemic way to "control" is not **regulation** or still better **self-regulation**.

Pleasantly, LE MOIGNE argues that cutting a sausage in regular slices can be satisfactory, but that the same method applied to a chicken would not give good results.

D. DURAND describes as follows the successive stages of modelization in systemic terms:

"- Identification and **classification** of the **elements** of the system (in order to distinguish) the **elements** in a number of **classes**... taking in account (their) dynamic as well as static properties ... and establishing a certain **hierarchy** among them.

"- Defining the **relations** among the **elements**... This is usually done by establishing a **matrix**... which moreover allows to define the direction of the **relations** from one **element** to another.

"- **Generalization** which is the extension to the most numerous possible **situations**, of a **model** which has been found valid in a number of observed **situations**.

"- **Induction**, a more ambitious **operation**... which aims at the replacement of one or various given **models** by one more abstract and more universal one" (1979, p.58).

2173

MODELIZATION BY COMPUTER (Limits of the)^{3) - 5)}

P. DENNING states such limits in the following way:

"As part of our modeling efforts, we must come to understand the **domains** over which a given **model** is reliable, partly reliable, or unreliable. We must also understand the **situations** in which modelization can be useful as a way of grounding speculations about the future **dynamics** of systems.

"Systems whose **rules** can evolve or change in unpredictable ways are unlikely to have a reliable predictive or speculative **model**.

"We must be careful with the **output** of **models**, being constantly skeptical that these **output** are "**facts**" or are accurate **descriptions** of the world. In our technological age, it is easy to accept the claim that every **phenomena** can ultimately be modeled, given sufficient **knowledge** and computational **resources**. There is reason to doubt this faith.

"If our mood makes us disinclined to accept **complexity**, it is easy to substitute the **model** for reality and to confuse our opinions with "**scientific facts**" supported by the **model**" (1990, p.498).

DENNING admits however that in limited **domains**, it is possible to create **models** of **complex systems** with human participants. But we do not know where the limits are.

This does not preclude using computers to gather and process **information** and make **conditional predictions**, whenever possible, "namely **domains** in which the **rules** are known in advance".

"In all cases, however, we must let the computer support the **decision-maker**, and not let the computer make the **decisions**" (Ibid.).

2174

MODELIZATION (Expediency in)^{2) - 3) - 4)}

J.W. SUTHERLAND describes as follows the unacceptable roots of expediency in modelization (a cause of not a few disasters in **human systems** in general):

"We need a solution but lack an effective instrument to arrive at a solution (a problem which has haunted those who, for example, are trying to develop **game-based models** to attack sociopsychological **behavior**).

"We need a solution, but to apply instruments congruent with the real properties (e.g., the true **complexity**) of the problem would be inefficient or economically infeasible – hence, for example, the tendency of **operations research** and industrial engineering practitioners to assume **linearity** in the face of evidently **nonlinear phenomena**" (1973, p.128).

The pseudo-solutions thus obtained are generally sub-optimal and sometimes, downright erroneous.

2175

MODELIZATION in System Dynamics⁵⁾

According to J.de ROSNAY, to modelize is to "construct a **model**, using the **data** produced by **systems analysis**: To begin with a complete diagram of causal **relations** between the **elements** of different **subsystems** is established (for example: ... influence of natality on **population**, of food rationing on mortality, etc.). Next, the equations which represent the **interactions** and **linkages**... are expressed in a convenient **programming language**." (1975, p.112).

The problem is to construct a "complete" diagram. If the **elements** (or the **subsystems**) are more than a very few, no complete diagram can be practically constructed. If we reduce the number of **components** by **aggregation**, we introduce the problem of establishing sound (in whom's view?) **criteria of aggregation**.

2176

MODELIZATION METHODOLOGY (Systemic)^{1) - 2)}

A. CASELLES MONCHO and J.L. USO DOMENECH propose the following general systemic modelization methodology:

"1. Identification of the **elements** to be considered according to the objectives of the modeler. Degree of detail or **aggregation**.

"2. To give a name, a unit of measure and a **range** of possible values to each **element** determined. So the **elements** are converted in mathematical **variables**.

"3. Identification of the causal dependencies among the **variables** considered.

"4. To assign an equation or table of values to each dependency previously identified.

"5. To **program** the **model** for a computer.

"6. To verify that the **model** fits real **data**.

"7. **Validation** of the **model** for another **set** of **data** obtained from another similar system.

"8. To use the model for testing user policies" (1993, p.457).

The authors aim is the study of **decision-making** problems in enterprise **management**. This type of modelization could however be also used in other fields, as for example, **ecology**.

Their proposals should possibly be somewhat observed. In complex **situations**, it would be better to begin with a **consensual** critical scrutiny of the various participants **objectives**, in order to avoid man-made disasters due to unilateral views of some autocratic **decision makers**.

As to the 2nd point, it is not sure that all **elements** can be converted into mathematical **variables**, specially the motivations of the participants.

Causal dependencies may well be variable in **time**, i.e. at **short, medium or long term**.

Computer modeling (as stated by P. DENNING – see above), has some limits.

Finally, the model should be frequently **re-cycled**: Napoleon once said that the best way to lose a battle is to try to repeat a former victorious one.

2177

MODELS (Dynamic use of)²⁾³⁾

G. MINATI writes: 'The notion of Dynamic Usage of Systems is related to the **situations** in which the system to be studied is so complex that it is not possible, in principle (because of its structural, unpredictable **dynamics**) fully describe it through a single model, nor through a sequence of models. each of which is a refinement of the previous one. In case of so **complex systems** (e.g. biological, social, cognitive systems) this approach makes reference to the ability to select, among the available ones, a number of different models of a given system, in order to simultaneously use them in a systemic way, i.e. the investigator, while being aware of the intrinsic limitations of each one of the models of the same system, makes, not withstanding, use of their results in a "crossed way", taking into account even the mistakes and not only avoiding them. The **strategy** is not to find the "right model, but to use the available ones (available **knowledge**) in an effective way" (2001a, 2002b)

It is possibly more a matter of comparing relative **inconsistencies** than to speak of "mistakes". Models are constructed in some specific way and depend on viewpoints. They can be useful in a complementary way, even if not perfectly "correct"

→ **Homomorphism; Isomorphism**

2178

MODELS (Functions and uses of)^{1) - 2)}

B. WALLISER (1977, p.179-80) distinguishes the four following functions and uses of systems models:

- **cognitive**: The model is used to understand the **interrelations** between the system's **input** and **output variables**;
- **decisional**: The model is used to investigate how the **output variables** should be defined, taking in account the probable **evolution** of the **environmental variables**;
- **normative**: The model is used to define and state the required **relations** between **input** and **output variables** of the system;
- **predictive**: The model is used to **forecast** the **evolution** of the system's **input** and **output variables** in relation to the probable **evolution** of the **environmental variables** and to the defined **command variables**.

These statements seem somewhat restrictive. Models can also be used to describe and investigate other characteristics of the systems, as for instance **limits** of **dynamic stability**, **growth** regimes and their **limits**, internal **constraints** and **adaptations**, etc... provided for the use in the process of model construction of more recent systemic concepts, as **chaos**, **catastrophes**, **fractals**, etc...

Such research could be beneficial for the different uses described by WALLISER.

2179

MODELS (Mathematical) of systems²⁾

A. RAPOPORT discussed the possibilities for creating adequate mathematical models for real systems (1965), in the following terms: "**G.S. theory**... is primarily concerned with the **structures** of systems as defined by the **relations** which the **parts** of a system have to each other, in the way these **relations** determine the dynamic **behavior** of the system (its passage from **state** to **state**), and with the **history** of the system, i.e., its own **development** as a result of the **interactions** with its **environment**.

"A mathematical **general systems theory** provides **descriptions** of these three aspects of systems, namely **structure**, **behavior** and **evolution**, in abstract mathematical language. A typology of systems, accordingly, becomes a mathematical typology. Two systems are identi-

cal if the mathematical **structures** of their respective models are identical (or **isomorphic** to use the mathematical expression)" (1966, p.9).

It had possibly been better to say that two systems may have *more or less* similar mathematical models because their **structures** are **isomorphic**. Of course, RAPOPORT appreciates this point, as he writes, immediately: "The degree of **similarity** between the systems is estimated by the degree in which their mathematical models are related" (Ibid).

→ ("**G.S.T.: Mathematical aspects**").

A unified and synthetic mathematical **G.S. theory** does not seem to exist. What we have are a number of mathematical theories related to some specific **structural** or **functional** aspects of systems.

→ (see also: **G.S.T.: Mathematical aspects, and hereafter**).

Even now, mathematical models for **complex systems** remain a tall order: very much remains to be done.

2180

MODELS (Qualitative)^{2) - 3)}

The progressive **emergence** of G.S.T. goes with the development of mathematical **models** of a more qualitative character than the traditional ones. This corresponds to the need to study the **forms** of structural **organization** as well as the dynamic **transformations** that affect them.

Thus, G.S.T. makes a growing use of:

- classical **topology** (Formerly POINCARÉ's **Analysis situs**)
- **graphs** theory (KOENIG)
- **fractals** theory (MANDELBROT)
- **fuzzy sets** theory (ZADEH)
- **catastrophes** theory (THOM - ZEEMAN)
- **percolation** theory (HAMMERSLEY- GILLES de GENNES)
- deterministic **chaos** (LORENZ, SMALE and many more)
- so-called **games of life** (CONWAY)
- a renewed theory of interconnected **cycles** (EIGEN)

All these theories are in slow **process** of interconnecting and a coherent **set** of typically systemic **models** is now emerging, within however two well different **classes**: static **models** and dynamic ones.

2181

MODELS (Qualitative Analysis of)^{2) - 3)}

J. ARACIL seeks a way out of limited quantitative analysis of **dynamical nonlinear systems** and proposes the following **method**: "... when a **nonlinear** dynamical system is analyzed, before adapting a quantitative **criterion** relative to a **behavior mode** (attractor) is it convenient to study the full class of **behavior modes** that the system can show. That is, before trying to make a **trajectory** generated by μ fit some ob-

servations on δ , it should be analyzed if all the **behavior modes** that can show μ correspond to the ones that show δ . This is the purpose of the **qualitative analysis** of μ .

"To carry out this analysis we use the **phase portrait** of μ , in which the **attractor's structure** of the model μ is shown. Associated with every **attractor** there is a **basin of attraction**. The **basins** are enclosed by **separatrices**. The **state space** is partitioned in the **set** of **basins**. The **phase portrait** supplies an overall view of all the **behavior modes** the system can show." (1986, p.245)

ARACIL bases his qualitative analysis on THOM's **elementary catastrophes**, taking in account **situations** characterized by two alternating **attractors**. It should be interesting to study what happens when the system undergoes a **process** of **dissipative structuration**: this is obviously the case of numerous **concrete systems**, especially complex ecological, economic, business and social systems.

2182

MODELS: Some taxonomies¹⁾

The French author B. WALLISER (1977 - hereafter W) and the Catalan systemist P. VOLTES BOU (1978 - hereafter VB) established different, but more or less complementary taxonomies of models. They have been completed by this compiler (Hereafter F) and coordinated as follows (alphabetic order used):

- **Analogic**: A model obtained by substitution of a **set** of **interrelated** properties by another, **homomorphic** of the former.(VB)

"A typical example are hydraulic **artefacts** used to represent economical or traffic systems" (VB).

- **Closed**: A model that only includes **elements**, **relations** and/or **variables** corresponding to **endogenous states** of a system (W).

- **Digital**: A computer model constructed according to a **binary language** (F).

- **Disaggregative**: A model that can be subdivided into submodels relatively independent from each others (W).

- **Dynamic transferential**: A **linear stationary** and **continuous** model connecting in vectorial fashion **inputs** and **outputs** (W).

These models can lead to problems when one of the conditions limitative to **dynamic stability** is not anymore valid.

- **Formal**: A model established in a logical or **mathematical abstract language** (F).

- **Global**: A model aimed at describing the system as a **set** as complete as possible.(W).

Systems dynamics models aim at globality.

Not for being "global" is the model a complete **description** of the system. It is necessarily obtained by **aggregation**, which implies simplifications. The way this is done reflects the conscious or unconscious **decisions** taken by the **modeler**.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Unfortunately, when the results are assessed, they are seldom put into perspective.

As observed with the "**Club of Rome**" models, they become easily controversial.

- **Hierarchical**: A model organized along various **levels of complexity** (F).

When static, they are called "organigrams" (in French and Spanish) and supposed to represent an **organization** in the form of a **pyramid**. When dynamic, they emphasize **regulations** and **controls**. (Flow charts)

- **Iconic**: A model in which the relevant **elements** and properties are represented in a figurative manner at some specified **scale** (VB).

Examples are photographs, drawings, **maps**, **scale** models, BOHR's "planetary" atom, stellar system models, etc... (VB).

- **Interdependent**: A model that may only be fragmented into closely interrelated submodels, representing very strongly **interconnected subsystems** (W).

- **Macroscopic**: A model including only **interrelations** among **variables** at the global **level** of the system (W).

- **Metamodel**: A model of a higher **level of abstraction** which maps the properties of lower systems models into propositions of a higher **level of abstraction** (J.P.van GIGCH, after St. BEER, - 1986, p.3).

van GIGCH states "Of necessity, the metamodel is conceptualised in a **metasystemic** language or metalogic which can decide propositions and reconcile arguments which cannot be decided or reconciled in the **language** or logic of lower systems models" (Ibid).

- **Microscopic**: A model including only **interrelations** among **variables** at the **subsystems levels** of the system (W).

- **Open**: A model that also includes **exogenous variables**, corresponding to **inputs** from the **metasystem** or **environment** and **outputs** into the same (W).

- **Partial**: A model describing merely a fragment of a **subset of phenomena** in the system (W).

- **Physical**: A physical **representation** of the system in form of concrete **processes** (W).

Good examples are reduced models of aircrafts for aerodynamic tests; reduced models of harbours or river basins for the study of currents, silting processes, etc...

- **Recursive**: A model that can be fragmented into *successive* models offering the same intrinsic characteristics (W).

- **Sequential**: A model usable to study **processes** chaining in **time** (W).

In practice, it is quite difficult to create very **reliable** sequential models (i.e. useful for **forecasting purposes**), specially in **complex systems** which may present **chaotic behavior**. Most sequential models study the variations of only one **process**, assuming that all other conditions will remain constant.

- **Short, mean or long term**: Models that emphasize different **time spans** in the systems **behavior** (F).

While it is practically difficult to do, ideally short mean and long term models should be interconnected, even if this may lead to very complicated **periodic** or **chaotic** dynamics.

- **Simultaneous**: A model that represent the **whole structure** of a system at a given moment (W).

Such models could also be called "structural", or "**synchronic**". They are instantaneous and **static**, and thus unfit to trace any **process**. It should never be forgotten that these models practically suppress the **time** dimension and tend sometimes to generate the illusion of total **stability**.

- **Symbolic**: A model that uses letters, numbers and other symbols to represent **variables** and their **interrelations** (VB).

In this sense, "symbolic" is practically equivalent to "formal"

Obviously, a model may include various of the characteristics previously described... Moreover, even WALLISER's and VOLTES BOU's listing remains partial (see former entries).

Other authors proposed different taxonomies of models, some of them more or less complementary, and some others offering finer subdivisions.

A. ROSENBLUETH and N. WIENER (1945) proposed two fundamental classes:

- **Material models**, i.e. simplified material **representations** of some of the characteristics of the original system;

- **Formal models**, i.e. mathematical simplified **representations** of structural or dynamic properties of the system.

D. and G.A. MIRHAM proposed an expanded classification as follows:

"Physical models

Replicas: Biological twins; earthen relief maps Quasi-replicas: Silhouettes; planetarium shows

Analogue: White noise generators, statues

"Symbolic models

Descriptions: Textbook; metaphorical essay

Simulations: Operational, procedural description

Formalizations: Differential equation: Poisson distribution

"Hybrid models

Analogue-similar: Hybrid computer model of river **flow** and **storage**

Replica-descriptive: War gaming exercise

Replica-similar: Operational, computerized, gaming model

Others: Board games, such as Monopoly" (1975, p.43).

So many classes are somewhat baffling, but reflect the considerable **complexity** in the field of model building.

2183

MODELS (Use of Generic and Concrete)²⁾

J. ARACIL explains as follows the use of generic and concrete models for the study of **nonlinear dynamical systems**:

"Once a generic model M has been adopted, we have to choose the model μ M that "best" fits the **concrete system**. The fitting **criterion** between δ and μ is established from **observations** of the **time behavior** of δ . The model $\mu(p)M$ whose **trajectories** best fit the ones observed on δ will be adopted. This fitting **criterion** can be quantitative, formalized through a mathematical expression of the discrepancies between the data observed on δ and the ones generated by μ . It is very common to use the quadratic value of this discrepancy. This **criterion** has a strongly local character as far as it refers to a **trajectory** (the measured one) which is adopted as representative of the **behavior mode**. However, it is well known that a *nonlinear dynamical system can have many attractors and therefore, can show different behaviors associated to them*. In that case, if one adopts a single **trajectory** as representative of the **behavior** of the system, then one is self-restricted to one **attractor**, forgetting the other ones, and the analysis of the system is unfailingly defective" (1986, p.245).

This is a characteristic problem presented by FORRESTER's **systems dynamics**: what happens when some systemic **process** escapes from its supposedly normal **range of trajectories**? and what should be done in such case?

ARACIL's qualitative analysis of models tries to solve this problem.

2184

MODULARITY (Weak)^{1) - 2)}

The existence in **subsystems** of moderately **constrained networks**, which carry out some more specific **activity**.

A **subsystem** in a **complex system** is generally made of **modules**, whose **interconnections** allow for the global functionality of the **subsystem**.

An example is sight, an **array** of interconnected **perceptions networks** referred to **form**, **size**, distance, color and movement.

Modularity must not be overly **constrained**, in order to allow for **adaptiveness** within the constitutive **networks**.

Weak modularity could probably become a useful concept for the study of **social systems** as, for instance, **organizations** or even for the future construction of **groups of artefacts** endowed with **distributed artificial intelligence**.

→ **Hora and Tempus parable**

2185

MODULATION ²⁾ - ⁵⁾

A variation in the **amplitude**, **frequency** or intensity of a **wave** or **oscillation**.

Modulation according to a law or **code** allows for the **transmission** of **messages**.

2186

MODULE ¹⁾ - ²⁾

Any standard structural **element** that may replace another **element** of the same type or **class** in a system or a **subsystem**, or be added to it.

Modules are generally of finite duration, as for example molecules, **cells**, snow flakes, or living beings.

According to L. CARLSON-SABELLI and H. SABELLI "The universe is formed by **classes** of similar entities (modules) at each **level of organization** (electrons, sodium atoms, starfish, system theorists). This is the principle of uniform **structure** of nature (MILL) also called the principle of mass production (J. THOMSON). For each **class** of modules there necessarily is a complementary **class**: cation and anion; sun and planet; woman and man; teacher and student, etc.)...

"Modules can be exchanged for each other as **parts** of systems. An entity may readily change the system to which it belongs, but not its **class**. One module may replace another in a system without affecting its overall **function**. Modules, even when equivalent to each other within the **context** of a given **interaction**, may not be equivalent in relation to other **interactions**, and may be completely unique (e.g. snow flakes, human beings, books). Systems are formed by modules of many types, and often contain many individuals of each **class**. **Complementary** modules interact harmonically, conflictually and co-creatively. Social classes are obvious examples" (1993, p.682).

→ **Hora and Tempus parable**

2187

MONAD ^{2/3)}

An entity made of only one **element**.

This abstract term was created by LEIBNIZ (1646-1716) to characterize an indivisible unit of some substance conjectured to be the fundamental **element** of physical **reality**.

LEIBNIZ admitted however that monads could not exist without **relations** which each other.

The leibnizian concept seems to announce the notions of "**whole**" and "**system**".

→ **for comparison: Entitation; System (Isolated)**

2188

MONEY A systemic definition ^{4/5)}

"An agreement within a **community** to use something as a medium of exchange"

(Bernard LIETAER: pers. comm. Oct. 28th, 1996))

LIETAER states: "Money as an agreement, lives in the same space as other social **constructs**, such as political parties, nationality, gender or marriage. These constructs are real, even if they only exist in people's heads. The money agreement can be attained formally or informally, freely or coerced, consciously or unconsciously...

"The agreement is always valid only within a given **community**... Such a **community** can be the entire global economy (as is the case of the U.S. Dollar by treaty as long as it is accepted as reserve currency), or a geographically disparate **group** (such as Internet participants).

"Finally, the key **function** that transforms the chosen object into a currency is its role as medium of exchange" (Ibid)

In archaic **cultures**, a wide variety of objects have been used as currency: cowries shells, lumps of salt, beads, pigs, cows and generally any type of objects that can be given a so-called **value** and handled over in transactions, which are a specific form of **communication**.

2189

MONITORING ¹⁾

Watch keeping and registering of specific **data** about the **activity of a system** and/or the **changes** in its **environment**.

On this last aspect W.D. GROSSMANN and K.E.F. WATT comment: "Monitoring of the **environment** provides the basis for two tasks: **homeostasis** and **adaptation**, and **error** correction. Monitoring is necessary because no perfect anticipation is available, otherwise it would not be needed. Capabilities for anticipation will be vastly improved, but will remain limited because of partial **unpredictability** of systems. In fact, it can be expected that anticipation will be wrong very often, perhaps most of the time in **complex systems**" (1992, p.20).

The authors recommend: "Development of a **set** of guidelines which specify the maximum tolerable **deviation** of indices of potential threats from their "standard values" or "standard long-run **trajectories**" (p.37).

This would be doubtless very useful. It should however be supplemented by a kind of "qualitative" monitoring, corresponding to basic **mutations** related to the **emergence** of new **structures** and **functions** through **dissipation** in a world in which natural **homeostasis** of

ecosystems and human ones cannot anymore be taken for granted.

Monitoring can be improved in **time** as the most significant possible **changes** affecting **short, medium and long term trends** become more manifest, and as the possible impacts of some hitherto ill known factors become more visible, i.e. when the **observer** learns *what to look for*.

The results should be translated in easy to understand **form** for the use of **decision makers**, insisting however on the always somewhat imperfect character of the conclusions that can be drawn.

Monitoring in systemic terms should never be limited to some selected **processes**, isolated from **context**: it is the system as a **whole**, whose **fitness**, **stability**, or even global **evolution** in relation to its changing **environment**, should be watched.

2190

MONOCULTURE ¹⁾ - ⁴⁾ - ⁵⁾

"The cultivation of a single crop to the exclusion of other crops on the land, i.e. in contrast to having a **variety** of different crops on the same land" (UNESCO - UNEP, 1983, p.18).

"Monocultures are often very susceptible to pests and diseases because of their concentration" (Ibid).

Monoculture is a typical violation of ASHBY's **Principle of Requisite Variety**. It is also a typical case of **suboptimization** in the name of **maximization**.

This problem is of much wider scope than agricultural. One could speak of mono-anticulture in the fight against pests and pathogens, where we produce evermore resistant strains by a kind of "inverse **selection**".

One may even wonder if the present human overwhelming **population explosion** is not the result of a kind of gigantic and unconscious "monoculture" experiment. It is at least characterized by a massive destruction of biological **variety** and seems to lead to an increased susceptibility to global "pests and diseases because of... concentration"

The UNESCO-UNEP glossary proposes "multiple use" as a corrective policy, i.e. the "coordinated **management** and **planning** for the most judicious and harmonious use of the land on a **long term** basis under the concept of combining two or more uses and/or **purposes** with attention to **sustainability** and nonimpairment to the natural **resources**" (Ibid).

A general **understanding** of the systemic and cybernetic concepts and **models** seems a prerequisite for the adoption by economists, politicians and social leaders of corresponding politics worldwide.

2191

MONOTONY PRINCIPLE (of Arnaud DANCHIN)²⁾

Only a limited number of internal different **translations** are produced by a pluralism of receivers. (J.C. TABARY, 1989, p.279)

2192

MORALITY⁴⁾

"In a **social system**, the totality of the conditions for deciding the bestowal of esteem or disdain within the system" (K. BAUSCH, Glossary, Pers. comm., 2002)

This definition has been inspired by N. LUHMANN's views. It clearly describes morality as a socio-cultural values defining code, most generally based on non-rational mythical beliefs or religious faith. Morality is a symbolic generalization that reduces the full reflexive **complexity** of double contingent ego/alter **relations**... and by this generalization opens up 1) room for the freeplay of conditionings, and 2) the possibility of reconstructing complexity through the binary schematism esteem/disdain".

Morality is thus essentially a social **set of constraints**. However, it is clear that the obedience to these constraints is basically a mere insurance against getting in trouble.

Ethics on the contrary engages personal **responsability** for one's own **behavior**, and may in some cases lead to a rebellion against social constraints imposed by moral in the **meaning** of LUHMANN.

Consequently, morality is not universal in an absolute sense. Some specific **behavior** can easily be praised, or even made obligatory in one **culture** and abhorred and even prohibited in another. Examples abound.

Any morality, specific to a culture, is transmitted by conditioning, generally since the most tender age. It thus becomes ingrained and escapes any critical reappraisal.

This leads to a set of standardized behaviors, not anymore discusses by anybody (in German "**Gleichschaltung**")

In this way many possible **conflicts** are avoided eliminated or at least made infrequent and much more easily evaluated and reduced within a **community** that obey stable and clear **rules** and prescriptions.

Morality is, or better, moralities are thus basically social devices and as such quite different and more limited in scope than **ethics**, which is more concerned with the deepest human nature, man's relation with his living the deepest human nature, man's relation with his living and non-living **environment** and the most existential question marks. (See H.von FOERSTER and M. BRÖCKER, 2002)

2195

MORPHIC FIELD²⁾

A field of **information** which would exert a formative power over **processes** (adapted from F. DAVID PEAT, 1988, p.62).

This still quite controversial concept has been introduced by R. SHELDRAKE. (1982)

F. DAVID PEAT writes: "It appears that WADINGTON was moving toward a notion of **development** in which living **matter** in some way responds to a **field of information** which exerts a formative power over the **processes** of the **cell**..."

"SHELDRAKE has proposed that such **fields of information** do exist and influence the **structures** not only of living **organisms** but of inanimate **matter** as well. According to SHELDRAKE, all **matter** has an associated **field of memory** which plays an active role in guiding the formation of **structures** and various **processes**. Clearly if SHELDRAKE's idea is taken seriously, then it would extend the nature of **matter** by introducing a new **level**, that of active **information**" (1988, p.162).

And: "These morphic fields are a type of **memory** that acts like a formative **pattern** with regard to material **structures** and **patterns of behavior**" (Ibid, p.166).

SHELDRAKE formulated his "**Hypothesis of formative causation**", of Aristotelian flavor, and derived from the different **morphogenetic field** concept, as a basis for his morphic fields. J. CASTI resumes it as follows:

"1. **Morphogenetic fields** are physically real;

"2. These **fields** shape and organize developing plants and animals, as well as stabilize the **forms** of adult **organisms**;

"3. Each kind of cell, tissue, organ, and **organism** has its own kind of **field**;

"4. The **morphogenetic field** results from the actual **forms** of previous **organisms**" (1990, p.175).

As observed by F.D. PEAT: "Little in the way of original research has been done, so that the overall weight of evidence is not particularly compelling" (p.164).

Features like **anagenesis**, Pasteurian **asymmetry**, **aura**, **licker noise** in **criticality**, **holograms**, homeoboxes (in embryology), **non-locality**, **order from order**, **pattern recognition**, MINKOWSKI's **space-time** diamond, or **stig-**

mergy could be considered as related to the morphic fields hypothesis, since all imply some kind of informative **action** at a distance in **space** and/or **time**.

However, the different problem of *instant correlation* in **space-time** remains unresolved.

2196

MORPHIC RESONANCE²⁾

An hypothetical mechanism of a nonenergetic **transfer of information** at a distance from one entity to another.

This is another hypothesis proposed by SHELDRAKE to sustain his "**morphic fields**" concept.

J. CASTI synthesizes it as follows: "Morphic resonance... takes place on the basis of **similarity**, and involves a nonenergetic **transfer of information**. Thus, it is a kind of action at a distance in **time** and **space**." (1990, p.175).

As observed by CASTI, such views are anathema to most mainstream biologists, who question the "nonenergetic" **transfer** as well as the mysterious character of this kind of **action** at a distance. Similar problems arise with BOHM's **implicate order**.

If SHELDRAKE's views should be admitted, they would quite probably imply a fundamental rehearsal of our **representations** of **time** and **space**.

2197

MORPHISM²⁾

A behavior and, or **structure** preserving **mapping**.

F. SUPPE, who resumes B. P. ZEIGLER's "Theory of **Modeling** and **Simulation**" explains: "In the case of *modeling*, the morphism is a **mapping** from *base models* to *lumped models*. The former are (usually unknown) isolated (i.e. **input-free**) **automata** systems that structurally characterize a portion of reality (a closed body of potentially acquirable **data**); the latter, the *lumped models*, are (simpler) **automaton** systems. Similarly, **simulation** is construed as an appropriate morphism holding between the **computer program** specification and the **lumped model**. One simulates reality by correctly simulating a valid **model** of reality or its **base model**".

"Morphisms are **mappings** between systems which preserve **behavior** and/or "**structure**", and, depending upon how much is preserved, a **variety** of different types of morphisms are possible" (1978, p.128).

It is thus very important to understand that only some specific **parts** of **behavior** or **structure** are mapped, which imply again, this time in **computer simulation** that "the map is not the territory".

2198

MORPHOCATALYSIS^{1) - 2)}

"A **morphogenetic change** in a system's **structure** conditioned by that system's contact or co-presence with another system, **variable** or **event**" (K. KRIPPENDORFF, 1986, p.51).

KRIPPENDORFF comments on his definition: "... neither causes the **change** in the sense of forcing an **adaptation** nor provides instructions directing that **change** in the sense of an **organizational input**" (1986, p.51).

Thus, morphocatalysis seems akin to **coevolution** and could be a natural result of **asymmetries**, as proposed by H. KUHN (1976).

2199

MORPHODYNAMICS^{1) - 2)}

The discipline that "deals with **complex systems** formed of many physical particles of various species"

R. FIVAZ, who gives this definition, states: "Such systems generally are endowed of **stationary states** in which they subsist in the mean **term**. During this **time**, they deliver definite **functions** at a constant **rate** that maintain them in permanent **interaction** with the **environment**... The generic assumptions of morphodynamics include that **order** is acquired according to the leading modalities found in physics, namely through *transitions on cusps*, and that the *structures* so acquired perform the *functions* belonging to the **stationary state**" (1993, p.35).

R. FIVAZ writes: "Morphodynamics specifically concerns **complex systems** where **structures** and **functions** generate each other, i. e. each **structure** supports all or part of a **function** and each **function** participates in the maintenance of one or several **structures**" and "Morphodynamics considers **complex systems** as assemblies of distinct physical **subsystems** embedded in the natural **environment**. A morphodynamical system satisfies three constructive hypotheses:

1. **Structural hypothesis**: Each **subsystem** is ordered in **structures** specified by **order parameters** q_i coupled to external **parameters**; in technical terms, **subsystems** are driven **far from equilibrium** and switch **structures** according to **bifurcation** theory.

2. **Functional hypothesis**: Each **subsystem** carries out a **function** p_i at a rate depending on its **order parameter**; in technical terms, **subsystems** are open and exchange **energy** and **matter** with the outside.

3. **Ergodic hypothesis**: The natural **environment** includes a large set of external **parameters** l_i that fluctuate randomly in **time** and/or in **space**; in technical terms, all **configurations** of this **set** of parameters are accessed in due **time** with equal **probability**" (1996, p. 128)

It should be observed that **fluctuations** need necessarily the **time dimension**. Also, while it appears basically correct, the **ergodic** hypothesis thus formulated is ambiguous: the "due **time**" is quite variable according to the different **configurations**..

As **structures** may interact in a **nonlinear** way, "in the **long term**, these compounded **behaviors** justify the repeated applications of the **ergodic** hypothesis" (Ibid).

FIVAZ proposes a formalism to sustain his ideas.

2200

MORPHOGEN²⁾

"A mathematical **model** involving the **process** of reaction and diffusion of various unspecified chemical compounds" (J. CASTI, 1994, p.71 – after A. TURING).

Morphogens are still purely hypothetical **models**, none having "ever been indisputably identified in the lab" (p.78). It seems doubtful that any will ever be, because if they are more than **computer models**, they must be reciprocal **self-organizing processes**, different in every case, while similar in principle. In biological examples, according to CASTI: "... concentrations... are assumed to be determined by a dynamical system describing how the morphogens interact and change their **levels** and **types** over the course of time" (p.71).

2201

MORPHOGENESIS^{1) - 2)}

The progressive buildup of the structural **organization** of a system and of the **interrelations** among its **parts**.

Already in 1952, A. TURING demonstrated, at least theoretically that some chemicals **homogeneously** distributed at the start, may, by reaction and diffusion, lead to different concentrations, which can then form spatial **structures**. Allegedly, and against what CASTI states, these "TURING structures" have been obtained in France in 1990. (S. DOUADY and Y. COUDER, 1993, p.32).

Morphogenesis, once started, is unavoidably a systemic **process**. It is also a social one because it organizes the differentiation of **parts**, **elements**, **individuals** or **subsystems** that will have to interact during the whole existence of the system.

Morphogenesis thus defined takes place in a system already endowed with **organizational closure**. It consists in the progressive **development** of a **set** of **catalytic hypercycles** – i.e. **periodic phenomena** – which expresses its potential to reach a final **level** of **dynamic stability**.

During morphogenesis, any **growth process** remains closely channeled within maxima and minima **limits** (WADDINGTON's **chreods**). **Structural organization** may be modified,

even deeply, through geometrical and topological **transformations**, but never in such a way as to alter the initial and basic **identity** of the system.

According to H.T. ODUM, morphogenesis is a result of progressive **selection** of successive **loops** which become stabilized if and when some **outputs** are repeatedly fed back into those functional **circuits** that are able to produce them anew. (see "reward loop"). As the initial cause of such **circuits** he sees "the initial proliferation of many possible **connections** more or less at **random** (which) constitutes the **choice** generation" (1977, p.154).

The most significant part of this statement may well be "more or less": Absolute **randomness** is obviously impossible, as any system has some specific antecedents. (See the critique of von FOERSTER's "order from noise" experiment).

However ODUM's view introduces us into the social aspects of **self-organizing systems**.

For A. WILDEN, morphogenesis is the characteristic of a complex and evolving system which adapt itself by transforming its **structures**.

According to WILDEN the term should be reserved for the **behavior** of "complex systems, such as societies... No individual **organism** is able to adapt and develop itself outside of narrow **limits** – in view that any **growth process** is a **positive feedback** which must be inhibited – while the morphogenetic system can adapt itself by transforming its **structures**" (1972, p.58).

Again here, "narrow" remains a matter of definition.

It could possibly be said that any system undergoes a period of social **organization** (biological, neural or groupal of some kind), corresponding with its **growth**, before it reaches its mature **state**. Some basic original **template** creates and transforms the **structures** of the system in a repetitive **process** of at least partial deconstruction and reconstruction, i.e. reorganization of **interrelations** among **elements**. It would seem that this is confirmed by the research in developmental genetics by the 1995 Nobel Physiology laureates: E. LEWIS, C. NÜS-SLEIN-VOLHARD and E. WIESCHAUS.

As this **phenomenon** is **energy**-dependent, it would be necessary to harmonize this **concept** with PRIGOGINE's one of **dissipative structuration** in **systems faraway from equilibrium**. The difference seems to be between some development limitations by pre-programming (for ex. genetic, technical, economic, or socio-cultural) and a nearly wholesale new programming, after an overwhelming shattering of previous **order** through **giant fluctuations** induced by massive **energy inputs**.

A similar potential contradiction is latent in MARUYAMA's concepts of morphogenesis in systems which present "**deviation- amplifying**" **processes** (which could be – or not? equated to PRIGOGINE's giant **fluctuations**) and **morphostasis** in systems with mutual **negative feedbacks**.

Morphogenesis is system-constructive while **morphostasis** is system-stabilizing. But, if morphogenesis is not somehow **constrained** within **channels (chreods)**, and limited in time, it becomes system-destructive, even if it may in some cases lead to **the emergence** of a more complex system.

→ **Autogenetic systems precursor; Zero system**

2202

MORPHOGENESIS as EMERGENCE²⁾

F. ROBB considers morphogenesis as the basic **process** leading to **emergence**: "Morphogenesis, the **emergence** of a system of higher logical **order** or the construction of the existant **order**, involves dissipating much more free **energy** and would be a much more powerful **attractor** than **morphostasis**, providing, as it does, many **positive amplifying feedback loops**. Once the conditions are ripe for morphogenesis there must follow a cascade of **events** leading to a more efficient **energy dissipating system**" (1990, p.141).

Dissipation, in the BÉNARD's sense, produces **structuration**, i.e. the appearance of new "**forms**". In this way the use of the word "morphogenesis" (shaping of **form**) seems justifiable.

2203

MORPHOGENESIS (ENVIRONMENT and ENVIRONMENT in)^{1) - 2)}

Provided the former **emergence** of an **archetype**, the construction of new **elements** or individuals of the same type seems to obey the two basic following **rules**:

1. There exists an internal **mode of organization** of the **endogenous parts**, based on an *implicit* blueprint of their **interrelations**, which leads to the production of characteristic **structures** and **functions**.

This seemingly tautological concept reflects probably an *aptitude* for **co-operation** at the superior **level of organization**, already present in the **archetype**.

2. Environmental **signals** serve as **trigger** factors or as **constraints**.

A good example is the construction of the neuron's axon and dendrites, as researched by M. KIRSCHNER and T. HUTCHINSON (1986, p.329-342).

2204

MORPHOGENETIC FIELD²⁾

"An assembly of functionally coupled **cells** whose **development** is under the **control** of a common regulatory **process**" (G. NICOLIS & I. PRIGOGINE, 1978, p.24).

Such a regulatory **process** in a growing living **organism** secures the coherent ordering of its **parts**.

Morphogenetic fields secure that the dog will have four legs, two ears, two eyes, etc. and that all these **parts** will be orderly located in the global **organism**.

Their nature and **operation** remain still ill understood, but is actively researched, notably in France in Germany, in the U.K. and in the United States.

In France, B. WEISSBERG distinguishes static **fields** from dynamical ones, all however characterized by **rhythms** and **rhythmic synchronies**. For him, spatial **organization** is borne out of the "separation of territories corresponding to opposed **phases**" (an idea reminiscent of SABELLI's complementarity of **opposites**), while "**periodical signals** lead to **periodical responses**". Moreover, dynamic **fields**, (or **toroids**, or **vortexes**, or whorls) result of the **interactions** between two or more **periodic fields**. Finally, "a disappeared **periodic field** may leave marks of its geometric **structure** in an appropriate **medium**". This seems to correspond to PRAT's "**aura**" (1968, p.3-19).

In England, B. GOODWIN states: "The spatial **organization** of the **whole** derives from principles relating to global **field behavior**, together with **constraints** coming from the properties of the entities which are generated as **parts**" (As quoted by J. CASTI, 1990, p.171).

Morphogenetic fields seem to be related to "the existence of inhomogeneous **distributions** of chemicals, the so-called **morphogens** throughout the morphogenetic **field**" (I. PRIGOGINE and P.M. ALLEN, 1982, p.19).

According to G. NICOLIS and I. PRIGOGINE: "This suggest that at least early morphogenesis is a **symmetry-breaking process** associated with the formation of spatial compartments in a hitherto **homogeneous tissue**" (1978, p.25).

Again, this seems in accordance with the 1995 Nobel Physiology laureates research in developmental genetics. (New Scientist, nr 1999, p. 6, 1995).

Morphogenetic fields should not be confused with SHELDRAKE's **morphic fields**, even if this author rely on morphogenetic fields to establish his "Hypothesis of formative causation".

2205

MORPHOLOGICAL RESEARCH⁵⁾

"A **forecasting** technique used in both **Operation Research** and **Market Research** which involves **forecasting** and **goal-setting**" (I.G. BLOOR, 1987, p.31).

This is a very systemic technique. BLOOR expresses: "The core part of the technique requires "total thinking" exploratory **processes** (i.e. gathering and analysing **data** in **context** and not isolation such as assessing the **effects** of a new technology on an industrially depressed area). The results are **predictions** relating to a "whole future" for an entire **organization**. **Morphology** is the science of the study of the **structure** or **organisms** in a complete **state**".

The FUSCHL Group proposed in 1984-85 the use of multi-dimensional **matrixes** to develop morphological analysis.

"Each multidimensional intersect would contain **information** on how the various **categories** of the various **taxonomies** of **parameters** (represented by all axes) interact with each other" (L. TRONCALE, 1985, p.73).

While this kind of **matrixes** – very complex in themselves – would not yield results of higher quality than the **inputs** themselves, they should at least offer an all-embracing **combinatorics** of **linkages**, some of them probably unexpected and interesting.

2206

MORPHOLOGY¹⁾

The **structure** and **forms** of a system.

The science of **forms** and their **transformations**.

The term was originally introduced by GOETHE (1749-1832), with the **meaning** of "Study of **forms** and their **changes**" (A. GOPOLD, 2000, p. 101)

The subject has been extensively researched in botany through phyllotaxis (by the brothers BRAVAIS, by HOFMEISTER during the 19th Century and more recently other researchers (S. DOUADY and Y. COUDER, 1993), and more generally by d'Arcy W. THOMPSON (1916/1952) and, at a higher **level of abstraction**, by CH. LAVILLE (1950).

Morphology is, of course, the progressive and final result of a **morphogenetic process** or, in D. BOHM's terms, of a "**generative order**", a possibly more general notion, because BOHM's global "implicate order" **embeds** every possible type of **morphogenesis**. In D. BOHM and F. DAVID PEAT's words: "... the inclusiveness of **orders**, one within the other, is no longer a mere abstract **subsumption** in the sense that a more general **category** contains its particulars. Rather the general is now seen to be present **concretely**, as the **activity** of the **generative principle** within the **generative order**" (1987, p.164) (emphasis ours).

Morphological properties – as a typical systemic subject – show quite interesting **isomorphies** between numerous systems and **organisms**. These can be framed within very general

underlying properties of **energy fields** and, at a still more abstract **level** by mathematical regularities through **FIBONACCI series** and the related **Golden Section**.

In a more specialized **meaning**, in linguistics and applicable to artificial intelligence, morphology is the study of word formation, derivations and flections.

2207

MORPHOLOGY (Dynamic)²⁾

Capacity of the system to maintain its **structures** and **functions** (or **organization**) during a long lapse of **time**.

This expression has been proposed by L.von BERTALANFFY (1969, p.81). It refers to the set of the **steady processes** which provide the **maintenance** of the system.

The subject has been enormously enriched first by classical **topology** and, more recently, by the concepts and **models** of **catastrophes**, **fractals**, **dissipative structures**, **bifurcations** and **chaotic behavior**.

2208

MORPHOMETRY (Geometric)²⁾

A discipline which quantifies the geometric **similarities** and dissimilarities among the **forms** of living beings.

The original idea belongs to W. d'ARCY THOMPSON (1916).

It was based on the study of **topologic** deformations, through the comparison of a number of **homologous** points taken on two **objects** (D. BRUNO & B. LAURIN, 1997).

It is now used in paleontology as a tool to measure the morphologic distance between species which are supposed to belong to a specific evolutive line.

It could however probably be applied to any evolutive series of objects, even man-made **artifacts**.

2209

MORPHOSPACE²⁾⁵⁾

The **domain** of space wherein a specific regional **regulation** imposes defined **processes** and **forms**.

This is a biological concept, related to the orderly **self-construction** of living beings. Its first inspiration can be however found in the 19th Century CHLADNI's magnetic figures and in W. d'ARCY THOMPSON's work on "**Growth and Form**" (1916).

2210

MORPHOSTASIS^{1) - 2) - 4)}

"The **processes** in **complex system-environment** exchanges that tend to preserve or maintain a system's given **form**, **organization** or **state**" (E. LASZLO, 1974, p.35).

"Character of a system which in spite of **perturbations** it must endure, goes back to one of the **states** included in its **repertory** and maintains its **organization** within clearly defined limits" (p.35).

To maintain itself in morphostasis, the system needs to be able to correct any **deviation** from the **set** of its admitted **repertory** of **states**. This is obtained by a predominance of **negative feedbacks** when the system is coming too close to some **instability threshold**.

Morphostasis is also a necessary consequence of **organizational closure** and **auto-poiesis**.

LASZLO gives the following example; "**Negative feedback** (morphostatic) **processes** dominate when **innovation** in a society is at a low ebb and the society is primarily devoted to coping with its **environmental** contingencies through the existing **norms** and **codes** of organized **behavior**" (Ibid, p.36-37).

2211

MOSAIC²⁾

A patchy spatial **distribution** of **elements** or conditions of different **classes** in an **environment**.

This type of **situation** happens in mostly **heterogeneous** and not strongly **hierarchic** and **integrated environments**, as for example **ecosystems**, **sociosystems** and global economic systems.

It is conducive to **variety** and **resilience**.

Mosaics correspond to:

- **heterogeneity** of **sets** of **elements** endowed with different characteristics.
- fluctuating and shifting occupancy of specific **territories**.

However a more general **homogeneous** common **substrate** or **medium** is a requisite.

Ecosystems, offering a wide **variety** of local conditions, are normally mosaics. It can be also the case of **socio-technical** and **cultural systems**.

→ "**Patchiness**"

2212

MOSCOW SYNERGETIC SCHOOL (The)¹⁾

This scientific school, a part of the Keldysh Institute of Applied Mathematics (Prof. S.P. KUDYUMOV) and the Institute of Mathematical Modeling (Prof. A.A. SAMARSKII) of the Russian Academy of Sciences, is the leading school in the field of synergetics (the theory of **self-organization** and **evolution** of **complex systems**) in Russia.

Its activity is centered on the exploration of very fast developing **processes** and of their self-strengthening in open **nonlinear** media, so-called blow-up **regimes** as well as various types of blow-up in the bibliographic section.

"The research is focused on the analytical methods of solution based on complicated **nonlinear** equations ... as well as on computer experiments with evolutionary **processes** in open **nonlinear systems**. **Synergetics** is developed ... as a theory of non-stationary localized **dissipative structures** which are a new type of ordered **structures** in systems with **nonlinear positive feedbacks**. (It is) viewed as a theory of fast evolutionary **processes**, the formation of localized **structures**, their **transformations**, **co-evolution**, **synthesis** and **decay**".

The main lines of research are defined as follows:

"1. The investigation of **mechanisms** of the **processes localization** in form of **structures** of an open **nonlinear medium**...

"2. The idea of **discrete spectra** of **dissipative structures-attractors** in open **nonlinear media** has been propounded...

"3. The exploration of very fast developing **processes** and of their self-strengthening in open **nonlinear media**, (so-called blow up **regimes**...)

"4. ... the principles of **integration**, construction of complex **structures** from **structures** which develop with different speeds and are at different stages of **evolution**.

"5. The revelation of the principles of **non-linear** management (the crucial role of weak, but **topologically** rightly organized influences upon **complex systems** for effective management" (Quotes from a pers. comm. by Prof. Elena KNYAZEVA, (knyazeva@iph.ras.ru)

2213

MOTIVATOR^{1) - 4)}

"The generator of system needs." (I.V. BLAUBERG et. al., 1977, p.163).

This term has been proposed by QUASTLER in his paper "General Principles of System Analysis" (see BLAUBERG et al., p.163).

It appears somewhat anthropomorphic, even if the genetic code in a **living system** could be an example as well as the basic **set** of **values** in a human **group** or the by-laws that reflect these **values** and constraint **activities**.

2214

MOTOR^{1) - 2)}

"The **subsystem** which moves the system or **parts** of it in relation to part or all of its **environment**, or moves **components** of its **environment** in relation to each other" (J.G. MILLER, 1978 p.3).

This is the ninth of J. MILLER's **20 critical subsystems** of a **living system**. It is a **subsystem** that processes **matter** and **energy**. In living beings, arms or limbs are motors. In **organizations**, examples are cranes, tractors, trolleys, moving assembly lines, etc... In the

supranational system railroads, airplanes, seafaring vessels, trucks, etc... seem to perform motor roles.

2215

MOVING AVERAGES²⁾

"A flexible mathematical **method** of smoothing statistical **data**" (E. Dewey & E. Dakin, 1952, p. 248)

This smoothing process is of great interest for a better understanding of the fundamental evolving **trends** in **growth** curves.

The authors give the example of a 2 year moving average applied to a collection of annual data. For instance, it can be done in a progressive way by adding series of 4 successive yearly totals and dividing the result by 4. Thereafter, pairing the results and dividing them by 2, the most extreme **fluctuations** of the base data are smoothed.

The authors state "...a moving average has no effect on the **period** or length of the series being averaged. But it does have an effect upon the **amplitude** of the **waves**" (p. 251)

Moving averages eliminate the apparent general **randomness** of data and show the basic **rhythms** of the **process** under study.

2216

MULTI-AGENTS SYSTEM^{1) - 2)}

A **network** composed of numerous interconnected **elements** or individuals.

This very general **model** is derived from the concept of distributed **artificial intelligence**.

As stated by J. ERCEAU and J. FERBER, it offers a frame for the study of: "... the **behavior** of a **set** of more or less expert entities, more or less organized along social type laws. These entities or *agents* benefit from a certain degree of **autonomy**, and are immersed in some **environment** in which and with which they interact. They are structured around three **functions**: to perceive, decide and/or act. They can be physical **entities** (sensors, processors, vehicles, ...) or abstract ones (tasks to be performed, movements,...). Through reciprocal information transmission, they become able to act on their **environment** and upon themselves, i.e. to modify their own **behavior**. To this end, they are endowed with a *partial representation* of this **environment** and with **perception** and **communication** means".

"As their **behavior** is based on an a priori or on *acquired knowledge*, agents include two main features. The first one is a *social tendency*, oriented towards the collectivity: this is the conversational and relational **domain**, and the corresponding **mechanisms** and associated **knowledge** bases are related to the **group's activity**. The other is the *individual*

tendency. in this case, the register is about **knowledge** and **behavior**, with **mechanisms** and **knowledge** bases including **rules** for the internal workings of the agent" (1991, p.752).

What the authors describe are **networks** of artificial agents (robots of limited individual abilities). But the **model** also strikingly suggests **analogies** with human and, probably, insects societies.

Networks of this type are most generally decentralized, since their **organization**, while in need and in search of **coherence**, is a result of more or less free, local and specific **interrelations**. As an example, R. BROOKS proposes micro-robots "societies" that would be used for planetary exploration, in which case the sideral distances make **efficient communications** with any earth based users quite difficult, due to **time lags** (1989).

2217

MULTI-AGENTS SYSTEM STRUCTURE²⁾

J. FERBER describes (1999) the multi-agents system, which includes the following aspects:

"1- an **environment**, that is, a **space** which generally has a volume

2-a set of **objects** that is situated, that is to say that it is possible at a given moment to associate any object with a **position** in the **environment**. Some objects are passive, that is they can be perceived, created, destroyed and modified by active objects (note of ed.: active objects are supposedly "agents")

3-an assembly of agents, which are specific objects, representing the active objects of the system

4-an assembly of **relations**, which link objects (and thus agents) to each other

5-an assembly of **operations**, making it possible for the agents to perceive, produce, consume, transform, and manipulate objects.

6-operators with the task of representing the application of these operations and the reaction of the world to this attempt at modification, which we shall call the laws of the **universe**" (1999)

To speak here of "the world" and the "laws of the universe" seems a bit of an overstatement. Possibly the author wanted to say "environment"

In any case, this proposed **model** seems applicable to a number of quite different types of **self-organizing systems** (natural or artificial)

→ **Artificial life; Parallel distributed processing; Relations; Stigmergy; Swarm; Zero system**

2218

MULTIDIRECTIONALISM¹⁾²⁾

A **communication process** which combines **top-down** communication with **bottom-up** (or sideways) feedbacks.

Basically, multidirectionalism needs and uses **networking** and gives voice to any participant who wants to take an active role. Such a stand moreover enhances the work of all participants and empowers the **group** as a **whole**.

It does not however necessarily implies that the group's **activity** is positive for the society as a whole.

→ **Multiperspectivism; Unidirectionalism**

2219

MULTIDISCIPLINARITY^{1) - 3) - 4)}

"A collective study by many specialized experts of a complex project or problem" (Ch. FRANÇOIS, 1986, p.114).

Ch. FRANÇOIS carefully distinguishes multidisciplinary from **interdisciplinarity**, or **transdisciplinarity**.

He writes: "Multidisciplinarity reflects the ever growing need for collaboration among many disciplinary specialists for the management of **complex systems**. Unfortunately, most of the multidisciplinary meetings – especially those which must produce some critical **decision** on practical projects – are merely confuse and confusing caucuses. Long debates may lead only to deep and damaging misunderstandings, due to the lack of a common conceptual **language** and an integrated view of the system to be managed (ACKOFF's *messes*)" (Ibid).

Thus, while the multidisciplinary approach is obviously a practical necessity, it may at the same time be clearly insufficient and in dire need for a systemic **transdisciplinary language**.

2220

MULTIDISCIPLINE GROUP^{1) - 4)}

"... a group of people who together possess all specialized skills necessary to perform the **operations** confronting them" (J. JOHANNESSEN & A. HAUAN, 1992, p.174).

About such groups, the authors emphasize that: "The main idea, however, lies not in the **design** of the group but in its functioning".

The MDG is useful only if its participants possess and use "**communication competence**", which allows for fruitful **interaction** and opens the possibility of **interactive planning** through **participative design**.

2221

MULTI-EQUILIBRIUM²⁾

Characteristic of a system which possesses various equilibrium points and is able to switch suddenly from one of these to another.

Each of these equilibrium positions is a punctual **attractor** and the **transitions** between them are the different elementary **catastrophes**.

The system can generally switch back to former positions. Each equilibrium position is characterized by a different **behavior** of the system.

→ **Ergodicity**

2222

MULTIFINALITY¹⁾

The possibility for a system to reach different final **states**.

Of course, a given system does reach only one final state, selected from the set of all initially possible ones through the successive specific conditions it encounters in its **environment** during its **history**.

→ **Equifinality**

2223

MULTIFOCALITY^{1) - 2)}

An organizational way "...characterized by numerous centers or foci of likely **interactions**, spread through an area, each focus being as far as possible self-sufficient" (S. BOYDEN, 1978 – quoted by W.D. GROSSMANN and K.E.F. WATT, 1992, p.8).

These authors state: "In a multifocal system, the **breakdown** of an **element** or of a whole focal point will not really affect the rest of the system because of the self-sufficiency of the **subsystems**" (p.9).

This may be over-optimistic, since the **breakdown** may affect a really critical **subsystem** (for instance the one securing **energy inputs**), but nevertheless it is generally a good bet. Multifocal systems however still need global **coherence**, **monitoring** and **regulation**.

Multifocality is closely related to **heterogeneity**.

2224

MULTILECTICS^{1) - 3)}

An intellectual **methodology** for the study of "qualitative **transformation processes** in which there are three or more systems that interact **synchronously**" (R. RODRIGUEZ DELGADO, 1991, p.8).

Introducing this neologism RODRIGUEZ DELGADO states: "**Processes of change** and qualitative **transformations** are not **linear**. In **complex systems** – individual and social – many **inputs** enter by different ways and are elaborated in many forms. Some **inputs** are preserved in **memories**. Multiple **outputs** impact on different **environments**. Therefore the **triadic** logical **structure** of dialectics appears as a **methodology** that can be useful only in some extreme cases" (p.8).

2225

MULTI-LEVEL DESCRIPTION^{1) - 2)}

The **modelization** of a complex system taking in account the different identifiable levels with their corresponding **subsystems** and the **interactions** between levels.

The best tool for multi-level description is J.G. MILLER **taxonomy of living systems** (1978).

For **ecosystems** H.T. ODUM offers useful tools (1971, 1976, 1983).

2226

MULTI-LOOP MODEL²⁾

A **graph** of interconnected **elements**, quantitative-qualitative **variables** or **concepts** representing some system.

M. MARUYAMA introduced these models in order to represent multi-loop **mutually-causal systems**. (1968, p.81-2).

Each **node** in the **graph** is connected in a selective way to some others by **in-** and **out-branches**. Of these, some represent **positive** and **others negative feedbacks**. **Flows** may circulate continuously, or not, between the **nodes**.

Models of the same kind have been widely used by J. FORRESTER in his **Systems Dynamics**.

Of course, the usefulness of these models depends on an accurate evaluation by the **modeler** of the **elements** to be integrated as **nodes** into the model, and of the characteristics attributed to the **branches**.

2227

MULTI-MODAL SYSTEMS THINKING¹⁾⁴⁾

V.DE RAADT writes: "Multi-modal systems thinking is a normative approach to systems science that draws from both conventional systems science such as that developed by von BERTALANFFY and his successors, and from DOOYEWEERD's theory of modalities"

"The aim of multi-modal systems thinking is to reform and expand science so as to add the norms of human life to our **understanding** of the determinative part of life. These **norms** address all areas of our life, including such things as marriage and child rearing, work, service to others, preservation of our heritage, **learning**, and ethically following our religious, cultural and social pursuits"(2001, p. 4)

Such a proposal seems to cover a basic-but widely forgotten-need, in western societies in particular. However, it implies the adhesion to specific **values** and norms **proper** to a specific **culture**.

There is probably a need to harmonize understanding of the values and norms systems across all **cultural systems** in order to avoid clashes between them, as a result of divergent **beliefs**

This will probably imply the arduous task of creating a **frame** of meta-**values** and meta-norms acceptable for all cultures and **rules** about transcultural reciprocities and respect

The most difficult issue is probably how to handle the seemingly natural intolerance frequently associated with strong unilateral belief.

→ **Methodology (Multi-modal systems)**

2228

MULTI-PERSPECTIVISM¹⁾²⁾⁴⁾

The most dangerous challenge that mankind will have to meet during the 21st C. is the growing confusion in all kinds of **issues**, worldwide.

A very sketchy sampling of these is as follows:

- the anarchic **growth** of megalopolis and the resulting numerous and intractable problems of most varied kinds
- the growingly complex ecological problems, turning evermore global (atmospheric pollution, water crisis, possible climate change, waste accumulation, etc.)
- the worldwide massive demographic **explosion**, possibly starting now to turn into an **implosion**
- terrorism, **anarchy**, warfare and massive corruption spreading in all continents
- growing hostility between some **cultures**
- foreign debt and financial crisis in many countries

All of these issues are known, but merely in a superficial ill-connected way. Their **interrelations** are ignored or ill understood.

This **situation** is now emerging in the **consciousness** of a growing number of people and systemic multi-perspective **models** are starting to appear.

H. BENKING, for instance, advocates the need to make a wide-embracing "**know-map**", in a coherently organized fashion, in order to become able to find the specific **information** we need (but within **context!**), and even possibly to discover more precisely what to look for". In this way, every "player" would know better where he is located in the general **frame** of **events**, with whom to start a **conversation** and eventually what to do and how to do it.

Benking adds that we do not only need a "good map", but also a compass to orient us when using the map and find (or become oneself) a good pilot in the cybernetic sense.

Other important proposers of multiperspectivism are:

- A. JUDGE, general secretary of the Union of International Associations (Brussels) who publishes an Encyclopedia about world problems and world **resources** to solve or manage them: <http://www.uia.org/uiadocs/aa-docdia.htm>
- The **Club of Rome** interconnected World Models, based on Forrester's **Systems Dynamics**

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

- J.de ROSNAY, who proposed his "**Macroscop**" as an integrative and also multiperspectival view of **wholes**
 - the "Systems Reasoning **Paradigm** of the Information **Image** and Nature" of M. BACEWICZ (Polish Systems Society at Wroclaw Technological University)
 - B.H. Banathy, J. WARFIELD, and I. MITROFF and H. LINSTONE's work on **Design** are also important contributions
- **Eco-cube/know map; Panorama; Scholasticism; Underconceptualization**

2229

MULTIPLE PERSPECTIVE METHOD ^{1) - 2)}

The use of different perspectives to study and manage some issue, **situation** or system.

Multiple Perspective Method has been proposed by I.I. MITROFF and H.A. LINSTONE (1993, p.97-108).

They propose three interconnected perspectives:

"T. The Technical Perspective.

O. The **Organizational** or Societal perspective.

P. The Personal or individual perspective." (p.99)

The authors define as follows the following key characteristics of their method:

"- The system **designer**, analyst or manager is a fundamental part of the system or **problem** being analyzed.

"- The **choice** of which particular perspectives to bring in a specific **problem** or to emphasize is a matter of one's ethical **values** and judgments, even though all complex **problems** invariably involve all three perspectives.

"- The value in using multiple T, O, and P perspectives lies in their ability to yield unique insights. None by itself suffices to deal with a **complex system**, but together they give a richer base for **decision** and **action**.

"- Any **complex problem** may be viewed from any perspective.

"- O. and P. differ in fundamental key characteristics from T. As a result, O and P inexorably move us beyond those features associated with basic science and engineering.

"- In the Multiple Perspective concept, we also cannot prove that a **set** of perspectives is the "right" **set**.

"- Two perspectives may reinforce one another or cancel each other: frequently they interact in a dialectic **mode**.

"- A perspective may change over time.

"- It is not easy to distinguish between an O and a P perspective: is the person giving his or her own or the **organization's** perspective?

"- In "real-life" **situations**, managing **problems** consists of at least three activities:

- a) analyzing alternatives,
- b) making **decisions** about which alternative to choose

c) successfully implementing the chosen alternative.

The T perspective focuses most strongly on (a) and least on (c); hence the gap so often deplored between analysis and **action**".

(For more exhaustive information, see reference)

Multiple Perspective Method is obviously part of a general systemic **methodology** of **problems management** and **systems design** presently forming.

2230

MULTIPLICATION ²⁾

"The **relation** of joining the **parts** so as to involve them with each other" (J. FEIBLEMAN & J.W. FRIEND, 1969, p.433).

This definition does not appear quite satisfactory in the sense given to it by FEIBLEMAN and FRIEND, as it implies an idea of **interrelation** of **synergetic** or *co-structural* type.

This may be seen clearly in the example they give: "The relation of skin, flesh, and seeds in a whole apple is multiplicative rather than additive because these **parts** are involved with each other in ways other than mere **aggregation**. (p.33)". The skin does not multiply the seeds, nor conversely.

One could understand that multiplication is an additive mode of **elements** or **parts of the same, or different** types, not any more under the guise of simple **aggregates**, as in **composite systems**, but as **structures**. For example, an increase in the number of clerks in an accounting service in a growing business may or may not increase the **complexity** of the accounting **subsystem**. But it generally does.

Eventually it could introduce the need for a new **control subsystem**, if the accounting division becomes too numerous and difficult to manage.

2231

MULTIPLIER (Social) ⁴⁾

The **effect** of enhanced collective **performance** on the performance of individual members of the group.

According to W.T. DICKEY and J.R. FLYNN (2001, p. 45-7) in human **groups** the betterment of the general performance of some kind produces an **environment effect** through **feedback** on the participant individuals. Those in turn, by enhancing their personal performance because they are thus stimulated, tend to positively affect the general performance of the **group**.

For ex. a society where the level of **knowledge** is increasing would incite the individuals to increase their personal **level** in order to avoid losing their **value** in relation with the global **activity** of the group.

Moreover this **effect** is becoming reiterative and accumulative and leads in turn to an increase of the general **level** of the group.

2232

MULTIPOLE ²⁾

"A more complex **black box** equipped with a certain number of **input** terminals of the same or different kinds" (M. BUNGE, 1979, p.254).

Compare with the "**dipole**", the simplest **black box**.

2233

MULTISTAT ²⁾

"A system formed by stable **subsystems**, associated through more or less lax **interrelations**".

As defined by B. WALLISER (1977, p.62), the difference with ASHBY's **homeostat** does not seem evident. WALLISER uses the concept to describe ecological **interrelations** between multiple species, or in economy to describe **constraints** between production and consumption.

2234

MULTIVERSE ¹⁾

A **consensual** vision and understanding of some **part** of the **universe**, obtained by a **group of observers**.

The concept has been proposed by H. MATURANA, within the frame of his physio-psychological study of the limits of **perception** and conceptualization, which led him to his "constitutive **ontology**".

It can be connected with G. JUMARIE **relativistic theory of information** (1980).

Moreover, according to MATURANA, also every individual lives in a multiverse (1988, p. 31, 1997), in accordance with the different selected **domains** of his/her experience, as for example scientific research, music, games, etc.

As expressed by J. MINGERS: "This appears to be close to SCHUTZ's (1967) ideas, within **phenomenological** sociology that individuals experience their lives within finite provinces of **meaning** and that consequently there exist multiple **realities**" (1990, p.577).

Of course, this view is a consequence of accepting only, or at least, to prefer, the subjective **meaning** of "**reality**".

2235

MUSIC FROM A SYSTEMIC VIEWPOINT ¹⁾

Musical works can be viewed from two different angles.

In the first place, a musical work has normally a **structure** defined according to certain **rules** of the art. For example, it can be western tonal music, or dodecaphonic, or jazz. Or it can follow the rules of the Indian Ragas. All these rules also imply typical **dynamics**.

Tonal music for instance has been thus described by LERDAHL and JACKENDORFF (1983) and by E. CAMBUROPOULOS in 1998

On the other hand, music is made to be perceived by auditors. While specific musical **perception** has not been widely researched, it is obvious that the people that we consider as musically "educated" are these who assimilated specific **frames of reference** corresponding to the acoustical nature of sounds and their combinations and/or the **rules** corresponding to a specific type of music (for ex. tonal or dodecaphonic rules of musical composition) (I. DELIEGE, 1999)

→ CASIS Journal, v.4, 1999, which contains 14 papers on music structures and perception

2236

MUTATION ¹⁾

A **structural, functional** and/or **behavioral change** affecting a **subsystem** or a system and, eventually their **interactions** with their **environment**.

Deriving from the biological **meaning** of the concept, in **systemics** it could be extended and modified: Any mutation affecting one **element** or **component** would normally induce a new general **structural** and **behavioral accommodation** of the system as a **whole** and **structural** and/or **functional** modifications of some of its **processes**.

Mutations may also have consequences for the **relations** of the system with its **environment**, provoking for instance modifications in its ethological **behavior**. It should be sometimes difficult to find out if **behavioral change** precedes or succeeds mutation and how is exactly the reciprocal **causal relation** between both.

2237

MUTUALISM ⁵⁾

A kind of complex **symbiosis** in **ecosystems** with numerous heterogeneous **components**.

Pollination by insects tends to maintain vegetal species which are necessary for the **survival** of the insects themselves as species. The same effect connects animals which bury seeds of the plants they eat, for example squirrels making stores of acorns.

There is also a kind of negative mutualism. Some trees defend themselves against insect

pests with biochemical emissions... and some pests even circumvent these defenses by enzymatically detoxifying these poisons... while the plant's emission acts as a call for the parasite's parasites! (P. GREIG SMITH, 1986; J.F. DOBRE-MEZ et al, 1995, 912-16).

Such natural **controls** are more than once destroyed by ill-advised human interventions, as for example the inadequately timed use of pesticides which kills not only the parasite, but altogether the parasites that could maintain them in check.

Mutualism is also a **relationship** between two **organisms**, which is beneficial for both.

For example, some trees obtain nutrients from fungi living on their roots. The fungi in turn obtain carbohydrates produced by the leaves of the tree

(It seems that some authors consider this collaboration as symbiosis)

Finally, mutualism may also exist among groups, as for example as reciprocal protection in fish **shoals**, or in herbivorous herds (zebras, antelopes) in which all members benefit from the collectively fostered vigilance against predators.

→ Commensalism; Cooperation; Herd effects; Parasitism; Stigmergy; Symbiosis

N

2238

NARRATIVES ¹⁾⁽³⁾⁽⁵⁾

An hypothesised capacity of the **brain** to construct more or less coherent histories about our successive experiences with the outside world (J. GRAY, 2002, p. 48)

This would be a typical **autopoietic process** and a general aid for **understanding** and subsequently coherent **action**.

This narratives upbuilding would seem to start very early in the brain of the baby and be a condition for further mental and psychic **development**.

It is very probably connected with the concept of "internal language" as developed by some psychologists.

And of course, no narratives could be expressed without a language. This introduces cultural **constraints** into the ways the narratives are constructed and evolve from childhood to maturity, as a **holistic** integrating process (L. VYGOTSKY; J. PIAGET)

According to M. GAZZANIGA it is the left hemisphere of the **brain** that "makes sense"

for us. It must thus be the origin of the narratives (J. GRAY, p. 49)

2239

NASH EQUILIBRIUM ²⁾

"A combination of **actions** by a **set of agents** such that, for each **agent**, granted that the other **agents** do not alter their own **actions**, its **action** is **optimal**" (S. KAUFFMAN, 1993, p.240).

However, John NASH, who first stated this rule around 1950, proved "that every game reaches a **state of equilibrium** where none of the players can improve his position.

Anyhow, according to KAUFFMAN, this **theory of games rule** has been used by J. MAYNARD SMITH as a **model** for an evolutive **strategy**.

"NASH (1950)... showed that in a "game" with any number of rational players who may have different aims but have full **knowledge** of the others' **actions**, there is at least one set of **strategies** which lead to an outcome where everyone's **aims** are fulfilled as nearly as possible" (Ch. ARTHUR, 1994, p.6))

"The Nash equilibrium was the mathematical basis for the nuclear standoff adopted by the major world powers from the 1950's onwards" (K. Devlin, New Scientist, sept.5, 1998, p. 48)

P. BAK observes however: "In the past, it has often been more or less tacitly assumed that large systems, such as those we find in biology and economics, are in a stable balance, like the sand on a flat beach. The leading economic theory up to now, the **general equilibrium theory**, assumes that perfect markets, perfect rationality, and so on bring economic systems into stable Nash equilibria in which no **agent** can improve his situation by any **action**. In the **equilibrium state**, small **perturbations** or shocks will cause only small **disturbances**, modifying the **equilibrium state** only slightly. The system's response is proportional to the **size** of the impact: **equilibrium systems** are said to be "linear". **Contingency** is irrelevant. Small freak **events** can never have dramatic consequences" (1996, p.28)

These assumptions must be considered sometimes as unrealistic and economic theories, for instance should be revised accordingly, in view of the deep technical and social evolution, worldwide.

The **rule** remains true as long as the basic conditions of the game do not change. In ecosystems this could explain the-at least theoretical- possibility of a climax.

But of course, environment change or mutations frequently alter the basic conditions.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

2240

NATURALISM ¹⁾³⁾

"The **belief** that all human faculties are emergent from the rest of nature and not dependent upon some special **operations** of a supernatural agency" (J.Z. YOUNG, 1978, p. 296)

YOUNG adds "Hence in **ethics** the belief that reliable criteria for right **actions** can be founded on factual **observations**, including **facts** about people" (Ibid).

Of course, in the long run, naturalism can be sustained only through experimental confirmation of specific **emergent effects**. Moreover, the very concept of **emergence** implies the appearance of more complex and integrating **phenomena** from so-called "lower" **levels** to "higher" **levels**. Accordingly, the study of this mechanism of **emergence** in itself is also the responsibility of the naturalistic approach, unless we would be back to **reductionism**.

→ **Falsifiability**

2241

NAVON ²⁾⁵⁾

A picture made of much smaller distinguishable **elements**. (see figure)

The **elements** may - or not - be similar to the global picture. Recently, navons have been used to test the **interactions** between perceptive and high attentional **levels** in the **brain** (J. McCRONE, 1999, p.27)

A navon can be **self-similar** at its two different **levels**.

A beautiful example is the engraving "Public opinion" by the Swiss painter and engraver Arnold BÖCKLIN wherein public opinion is repre-

New Scientist • www.newscientist.com

from: McCRONE, John: "Leftbrain, right brain" in New Scientist, Nr. 2193, July 3rd, 1999

Figure: see entry **Navon**

sented as a gigantic dragon made up of a myriad of much smaller dragons of a similar shape.

Navons present an intriguing perceptive **ambiguity** and has been used to study the effect of alternate **perception** in the brain. However this is a two-way **phenomenon**, i.e. "not a passive **process**. High-level attentional areas can tell low-level sensory areas what they should be concentrated on.

This **feedback** system can suppress the activity of some **cells** and increase the **sensitivity** of others. In effect, the **brain** can highlight what it wants to see"

And "There could still be a wiring bias, formed as the brain develops"(J. McCrone, 1999, p. 27-30)

see figure left column

As a source of **metaphors**, navons are suggestive of the subtle reciprocal **relations** between **levels** within **complex systems**.

→ **Brain circuits; Brain and Environment; Brain organization; Figure-ground; Intentionality; Neuron (Formal); Perception**

2242

NEARLY DECOMPOSABLE SYSTEM

→ **System (Nearly decomposable)**

2243

NEEDS ¹⁾

The basic requirements for a system to maintain its **identity** and **level of organization**.

E. LASZLO presents in a **hierarchic** form an "exclusive categorization" of needs, based on A. MASLOW's work. (1974, p.45).

This **hierarchy** is reproduced hereafter, but subdivided according to the growing order of **complexity** of the concerned **living systems**

- All living beings
- "Safety needs (protection from weather, other species)
- Social animals
- "Belongingness and love needs (family and social **group** membership)
- Humans
- "Esteem needs (having the respect of oneself and his/her peers in society)
- "Self-actualization needs (fulfilling one's potentials in his/her public and private capacity)
- "Cognitive needs (understanding one's relations to society and comprehending order in nature and the cosmos)
- "Aesthetic needs (perceiving beauty and order in experience)"

There seems thus to exist an **evolution** of needs toward progressive differentiation and **complexity** in **dynamic systems**, very probably related to the progressive **complexification** of the **brain**.

2244

NEGENTROPY ^{1) - 3) - 5)}

The measure of "quality or grade of **energy**" (L. BRILLOUIN, 1962, p.116).

Negentropy is, of course, the opposite of **entropy**, and represents the **availability** of useful **energy**.

It is also the opposite of **entropy** taken as statistical uniformity (so-called **disorder**). Negentropy can thus be interpreted as a measure of **order**. This led BRILLOUIN to connect the concept of negentropy with the existence of **information** (see **in-formation**).

BRILLOUIN writes, for example: "Whether he be a **Maxwell's Demon** or a physicist, the **observer** can obtain a **bit** of **information** only when a certain quantity of negentropy is lost. **Information** gain means an increase of **entropy** in the laboratory. Vice-versa, with the help of this **information** the **observer** may be in a position to make an appropriate **decision**, which decreases the **entropy** of the laboratory. In other words, he may use the **information** to recuperate part of the loss in negentropy, but the over-all balance is always an increase in **entropy** (a loss in negentropy)... This leads to the conclusion that both quantities are of similar nature" (1968, p.161).

The subject is however, as BRILLOUIN himself emphasizes, a thorny one: Negentropy cannot be simply equated with **information**. For a thorough discussion see BRILLOUIN's and SHANNON & WEAVER's works.

K. KRIPPENDORFF evaluates the term as "a non-recommendable near synonym for **information**. (It) has created considerable confusion suggesting that **information processes** negate the **2d. law of thermodynamics** by producing **order** from **chaos**" (In view of the recent development of "**chaos theory**", KRIPPENDORFF would now possibly write "**disorder**". He proposes as a "meaningful interpretation of negentropy... that it measures the **complexity** of a physical **structure** in which quantities of **energy** are invested, e.g. buildings, technical devices, **organisms** but also nuclear reactor fuel, the infrastructure of a society" (1986, p.52).

From a more specific systemic viewpoint, V.G. DROZIN wrote: "... negentropy is a measure of **complexity** of a system expressed in the number of its **parts** or **subsystems** and in their **variety**" (1975, p.9). This seems somehow insufficient: **constraints** over **interrelations** also are aspects of negentropy taken in this sense.

2245

NEIGHBORHOOD ²⁾

The **set** of all the points that surround a given point and are close to it.

Such a definition implies the necessity to define closeness in each specific case. Moreover, we also must decide if the points (or **elements**) that constitute the **boundary** of the neighborhood are or not **parts** of it.

This topological concept is important for the formalized **description** of systems and **sub-systems**. Also, **stable attractors** define neighborhoods, out of which a controlled **function** cannot normally escape.

("Vicinity" is also used)

2246

NEOTENY⁵⁾

The conservation in an adult organism of **embryonic** or juvenile biological **structures**.

One of the most curious case of neoteny has been observed in the mexican salamandra axolotl (*Amblistoma tigrinum*) that is able to reproduce itself at the larval state.

It has been conjectured that humans are neotenic anthropoids. If so, neoteny could be an evolutive **mechanism** through a longer maintenance of adaptive plasticity.

→ **Heterochrony**

2247

NERVOUS SYSTEM¹⁾⁵⁾

The study of the nervous system, specially in the human being, is obviously basic for the **understanding** of our **behavior**, our ways of thinking and our social **relationships**.

It is thus very significant for cybernetics and systemics. It is however not possible to develop the subject within the **frame** of this Encyclopedia (whose editor moreover is in no way competent to do it, even if he may have useful general **information**)

Only some more specific topics are presented in this work because of their seemingly central importance, but still in a very sketchy way. Among them are:

- the various entries about the brain
- frog's eye experiment
- HEBB's rule and reinforcement
- hippocampus
- learning as cerebral differentiation
- learning matrixes
- neural network
- neuron
- neuron (formal)
- synapse

Also closely related to the subject are:

- autopoiesis
- closure (organizational)
- constructivism and constructivist cybernetics
- coupling (structural)
- hypercycle
- intentionality (perceptive)
- memory
- model building
- observability, observation process, observer

- parallel distributed processing
- the various entries on perception
- reference frames
- synaptic weights

2248

NESTED INTERVALS²⁾

A sequence of intervals entirely included within a larger interval.

For example, the values of the terms of a convergent series are included within a maximum and a minimum value. Curves may also be nested: For example an **oscillation** between n and $n+1$, could be contained within an **oscillation** between $n-1$ and $n+2$.

→ **See also: Self-similarity in WEIERSTRASS function**

2249

NESTED SET²⁾

Any **set** which is contained in another **set**.

This is a rigorous condition in **hierarchies**, when every **element** of the lower **order set** must be included within the higher one.

2250

NESTING PRINCIPLE^{1) - 3)}

Any unit becomes, or is **embedded** as a **part** in some more global unit.

The principle is basic to J.J. GIBSON's way to understand **levels of perception**. In his words: "The smaller units are **embedded** in the larger units by what I will call *nesting*. For example, canyons are nested within mountains; trees are nested within canyons; leaves are nested within trees; and **cells** are nested within leaves. There are **forms** within **forms** both up and down the **scale of size**".

As a result: "The unit you choose for describing the **environment** depends on the **level** of the **environment** you choose to describe" (1986, p.9).

This is one more expression of the quite general **perception** of **levels of complexity**, very basic for any **systemic description**. The concept, which offers a dynamic as well as a static aspect, is closely related to those of **criticality**, **embedment**, **fractals**, **niche**, **subsystem**, **suprasystem**, **wholes** and **parts**, etc...

2251

NET²⁾

A **structure** including a number of **elements** and the **interconnections** among these **elements**.

Any net includes a limited number of **elements** and of **interconnections** as permitted by the existing **constraints**.

It distinguishes itself from its **environemnt** by the great number of its internal **interconnections** in comparison to the quite more reduced number of its external **connections**. It may become integrated in a **hypernet**. In that case, it is sometimes called a "subnet".

The **elements** in the net take their **decisions simultaneously** according to what they know about the global **state** of the net at that moment.

→ **Communication**

2252

NET (Access problem in a net)²⁾

In a parallel processing net, numerous independent **programs** need to communicate in a coordinated way. However they need also to obtain access to those **parts** which are of common use for the **whole** system and thus start to compete for general **memory** facilities or peripherals time.

J.P. SANSONNET writes: "(As) these interactions are asynchronous, this turns unpredictable their global **behavior**... It may happen, for example, that different tasks compete for common **resources** in a disordered manner and in this way very quickly critical situations appear, such as those called "Famine", or "Fatal embrace".

"Famine: Some tasks never obtain the **resource** they need - for ex. never accede to the printer to produce their **output**.

"Fatal embrace: Two tasks wait indefinitely for each other" (1988, p.1304).

Organizing the net and making compatible its interconnections is thus a fundamental requirement for correct and efficient **operation**. SANSONNET writes that, to avoid access problems "each processor may be endowed with some local **memory**. Each pair **processor/memory** thus becomes a small and relatively independent computer" (p.1303).

It is noteworthy to observe, when **simultaneity** replaces sequentiality, how the need for general **organization rules** pops up immediately.

→ **Contention; Parallelism; Processing: simultaneous or sequential; transputer**

2253

NET (Connection modes in a)

→ **Connection modes**

2254

NET (HYPER-)²⁾

A net including a number of lesser nets

In general, the hypernet defines the **connections** among the integrated **nested** nets and controls the **connections** with the global **environment**.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

2255

NET (NESTED)²⁾

A net contained entirely within another net.
Also sometimes called "subnet".

Generally various **interconnected** nets are included within the **global net** and some **communication** is possible among a number of **elements** pertaining to the different nets.

2256

NET Stabilization^{2) - 3)}

L. PERSONNAZ et al., who study the **learning process**, in relation to the network **model**, write on this topic: "If the **learning process** is correctly conducted, the **energy function** of (such) a net takes minimal values precisely for these **configurations** which have been presented to the net during the **learning process**." (1988, p.1369).

The **learning process** thus *defines* the net: This is equivalent to the "Lern-Phase" in **Steinbuch matrixes** (but in a more elaborated way).

The authors moreover state: "In other words, the net did compute its synaptic **efficiencies** in such a way that these **configurations** that it must memorize are minimal **energy stable states**,... **attractors** in the net's **space of states**." (p.1370).

The net thus reaches the minimal **level of entropy** production compatible with its specific nature.

2257

NETWORK^{1) - 2)}

A **structure** of **communication** links that allows for exchanges of **energy**, **matter** and/or **information** among the **elements** (**processors**) or **subsystems** in a system.

Basically, networks are: a) combinatorial, according to **rules**;

b) **auto-catalytic** by spontaneous construction of functional **cycles**.

Normally, each **processor** acquires a specific **activity**, i.e. specific links with other **processors**, which either act upon it, or are acted upon by it. This is why networks are easily represented by **graphs**, and particularly, oriented ones.

As noted by J.A. GOGUEN and F.J. VARELA, the network **model** is closely related to the concept of **recursion**, but in opposition to the restricted vertical concept of **hierarchy**: "The reciprocal **connectivity** of a **net** suggests the **coordination** of a system's **elements**; a **tree structure** suggests the sequential subordination of a system's **parts**, each **part** having its own well defined **input-output behavior description**". Consequently, these authors define a network as "a directed **graph**" (1979, p.36).

Any network must be pre-defined by appropriate **constraints**, i.e. a selection of the actual or potentially useful **links**, excluding those who should not be significant for a proper working of the system.

L.H. KAUFFMAN states: "A slight **disturbance** creates conditions of local imbalance through the net. The net preserves itself by correcting these imbalances, but in the **process** may create further imbalances" (1977, p.179) and... "... networks... are characterized by a **self-referential interdependence of parts** and the **whole**. The **behavior** is a matter of balance among the **parts** and the preservation of this balance under internal and external **perturbations**" (p.187).

Starting with an initial **situation** and quite simple **rules**, many systems generate themselves by constructing their own **intercommunication** network through a progressive **process of trial and error**, applied to successive **inputs**. See: "**Genetic algorithms; order from noise; Boolean functions**".

Conversely however, networks are difficult to program in the habitual sense, because the introduction of a ready made **algorithm** should inhibit their self **training** ability.

On the contrary, **processes** of self-**training** appear to be at work within the learning **brain**, the **perceptron** and the more recent so-called neural computers, as well as societies (human, ecological, and probably of robots in a not too distant future)

Nets **elements** work in **parallel**. Thus, at the same instant, many different **events** happen within the network. This leads to **chaotic determinism** in the **behavior** of the system.

A network has generally very numerous potential **states** implicit in the multiple possible combinations of its **elements**.

St. KAUFFMAN states that "Because all the **elements** act simultaneously, the system is... said to be **synchronous**. A system passes from one unique **state** to another. The succession of **states** is called the **trajectory** of the network" (1993, p.66).

Moreover networks have a *finite* number of **states**: "A system must therefore eventually reenter a **state** that it has previously encountered" (Ibid.).

This should possibly be somewhat qualified: Very **complex systems** have so many possible **states** that they may practically never reenter again a former **state**, while however some of its stable **parts** ("**frozen cores**" in KAUFFMAN's terminology) may do.

Once the network is organized, i.e. has acquired some specific **function**, this **function** responds to a **matrix of state transitions**.

Closely related subjects are: "**Connectionism**", "**Constructivism**" and "**Neural networks**".

2258

NETWORK ANALYSIS^{2) - 4)}

"A **planning** technique... used to plan and control complex projects, especially in the construction and engineering industries" (I.G. BLOOR, 1987, p.32).

There are different versions of this technique (see for ex. **P.E.R.T.**). In all cases, a global **space-time graph** of the successive projected tasks is established in view to define orders of priorities, compatible **simultaneities**, **time** schedules; to select the best **combinations** and to evaluate relative **costs**.

The technique requires a global view of the considered project and of its general **environmental** conditions, the present and as much as possible, the future ones.

2259

NETWORK and PARTS^{1) - 2) - 4)}

No part in a network is able to understand fully the network. This is the case for everyone of us, as an **element** of social networks of different kinds. We may only form working hypotheses about any network of which we are part.

Networks acquire **emergent** properties. H.T. ODUM writes: "The network of society has a form of thinking since it is a computer network in itself, quite over and above those it encompasses - the electronic computers of industry and the even more remarkable computer, the mind of man" (1971, p.245).

The **metaphor** could be somewhat overstretched, but in due time it may prove correct... and is in any case suggestive.

H.T. ODUM adds: "The network is doing things to keep itself regulated, adapted, and consistent with energetic laws that the individual cannot envision" (p.245).

2260

NETWORK BEHAVIOR^{1) - 2)}

R. ROSEN observes: "... the essential thing... is that the behavior of (such) a network is always the outcome of an **interaction** of pairs of antagonistic **activities**, one of which excites a particular **response**, and the other inhibits it" (1974c, p.171).

ROSEN uses the terms "**inducer**" and "**repressor**" to name such paired but antagonistic **processes**.

Thus the network behavior is basically **digital**, or **binary**, even if this aspect may be quite obscured by the numerous simultaneous **interactions** that constantly occur.

From another angle, it seems that natural networks, as for instance a river basin, or a system of geological plates, are globally able to minimize their **energy** expenditures, in accordance with some few implicit **optimization rules**. (YAM, 1994, p.17). This recently discovered and intriguing feature is still under investigation.

2261

NETWORK (Boolean formulation of a)

→ Boolean formulation of a network

2262

NETWORK (Causality in a)^{2,4)}

Causality in a network is kind of distributed.

Each **element** is a **causal agent** in its own right. It is however constrained in its **behavior** by the **inputs** it receives from the other elements. And in turn it will constraint the behavior of those elements which will receive its **outputs**.

Moreover, not all elements will receive or emit directly to each others. Some may even never receive some types of inputs. In such cases, specific **localizations** may appear in the network. This is possibly a **model** in the case of the progressive **organization** of the **neural network** in the **brain** (see "neurode"). On the other hand, no **transmission** is instantaneous and the resulting **time lags** will insure different conditions in different places in the network, as a result of differential spatial and temporal **propagation of effects**. In this way, the general **determinism** of the network can be somewhat disrupted locally.

A result is that any network will readapt permanently, somehow in the way of ASHBY's **homeostat**.

However the general behavior of the network would remain within the global - but lax - **constraints** imposed to the network either by the **context**, or by its constructor (in this last case, for ex. by a **back propagation algorithm**).

This model of network **causality** could possibly be also useful for research on complex social **interactions** in human **groups**.

2263

NETWORK: Described as a graph²⁾

St. BEER writes: "... the most useful scientific **language** for discussing ... networks... is really the theory of graphs..."

"... the graph as a logical entity, consisting of an arborescence of **binary relations** (is) to be treated by **Boolean functions**. Now, the modern mathematical statement of graphs is achieved with the help of the theory of **sets**, and it looks like subsuming all the other **descriptions** in one. (The **vertices** of a graph are regarded as **elements** of a **set** which is mapped into itself, of which **set** the whole graph is then a multi-valued **function**)" (1968, p.218).

Three different, but related, graph **descriptions** of a network can be thought of:

- The static "vertical" arborescence representing a supposedly invariable **hierarchy** (Example: the structural **representation** of an **organization**);

- A dynamic "horizontal" arborescence, representing the **flow lines** of the interconnected **variables** of the system in **time** (Example: **Critical paths** graphs);
- A closed **cyclical** graph, also allowing for the **representation** of the **dynamics of feedbacks** between **elements**. (Example: M. EL-GEN's **Hypercycles** graphs).

2264

NETWORK DIAGRAM²⁾

A global **representation** by a **graph** of the **flows** within a network.

Flows circulate from some compartments or boxes to others within the network. As an organized network is defined by specific **constraints**, not every compartment is communicated directly or indirectly with all other compartments.

H.T. ODUM states: "The number of possible boxes and the number of boxes actually utilized in the system are properties of the **complexity** of the network" (1971, p.37-8).

Quantitative **representation of flows** is better done through a **matrix**, which is however more abstract.

2265

NETWORK (Evolutionary)²⁾

"...an assembly which acts as the immediate **environment** and the material substance of an evolutionary system" (G. PASK, 1961, p.82).

According to PASK: "The network itself cannot be said to evolve (its possible **states** are always evident). On the other hand, the **active region** in the network which is the **system** we refer to as 'learning' does evolve" (Ibid).

Any network that is able to increase or modify its internal **connections** is a **learning system**. It should however seem better to distinguish "learning" from "evolution".

The basics of the subject was thoroughly explored as early as 1960 by G. PASK and H.von FOERSTER in their paper on "A predictive **model for self organizing systems**" (1960-61)

It has been renovated since 1985 by the study of the **neural networks** and the **connection machines**.

2266

NETWORK (Hopfield)²⁾

For a good introductory graphical description of this network, see P. DENNING (1992b, p.427-8).

HOPFIELD introduces **nonlinear dynamics** in computational networks. In DENNING's words: "HOPFIELD showed that his network can memorize **patterns** by storing them **directly** into the weights; no **training** is needed. There is a **feedback path** from the **output** of each unit to the **input** of every other unit, and all of these **paths** are assigned individual weights... Ultimately the network settles into a condition of **equilibrium**... If an **input pattern** does not ex-

actly match one of the memorized **patterns**, the network will reach **equilibrium** at the nearest memorized **pattern**. This **behavior** provides a means for restoring a **pattern** from a noisy or a partial version" (Ibid).

HOPFIELD's networks are somehow reminiscent of ASHBY's **homeostat**.

2267

NETWORK (Learning)^{2) - 4)}

G. PASK states that learning networks (which are **self-organizing systems** - see above Network, Evolutionary) need "...input **filters** which must be able to detect **arbitrarily chosen attributes**". (1961, p.86). In the case of the **brain**, for instance, those arbitrarily chosen **attributes** are selected through the sense **organs**: we are able to register red or blue light, but not infrared or ultra-violet one. Moreover, we must be able to pick up **distinctions** as for example differentiate red and blue, or in natural **languages**, specific sounds: a, i, u. (Characteristically, these written **signs** represent *different sounds* in different **languages**).

PASK observes moreover: "In our social **environment** we learn, not new **attributes**, but the yen to regard certain values of the **attribute** as identical" (Ibid).

Thus, the English sound 'a' is different from the French 'a' and, even from the Australian or North-American one. What one hears or sees is what one has been culturally trained to hear or see, within the basic genetic **determinism** of human speech or sight sensorial **structures**.

The same must be true - even if in a very different setting - for electronic networks constructed to recognize words or sounds.

2268

NETWORK (Matrix of a)²⁾

The **representation** of the **flows** within a network through a matrix.

The matricial **representation** is complementary to the graphical one, as it emphasizes the quantitative aspect of the **flows**. As stated by H.T. ODUM "The absence of a pathway in the **network diagram** is a zero in the matrix" (1983, p.20).

2269

NETWORK (Parallel- processing)^{1) - 2)}

A network in which "all **elements** compute their next activities at the same moment".

S. KAUFFMAN comments about this type of networks: "If we find order in **random** networks, than **random** parallel networks with **random** logic have **order** despite an apparent cacophony of **structure** and logic" (1993, p.192).

This **order** would be most probably **ergodic**.

¹⁾general information²⁾methodology or model³⁾epistemology, ontology and semantics⁴⁾human sciences⁵⁾discipline oriented

KAUFFMAN also observes: "... the current enthusiasm for **connectionism** and for **parallel-processing neural networks** is precisely that any such system almost inevitably classifies,... has internal **dynamics** whose **attractors** represent alternative **asymptotic states** of the network" (p.233). And the following statement may possibly be considered as another formulation of **autopoiesis**: "The alternative **attractors** in a fixed **environment** from which the network receives **inputs** can be thought of as alternative **classification** of the same **environment**. Similarly, alternative **environments** which **map** to the same **attractor** can be seen as **classifications** of those different **environments** as "the same" by the network. Thus such networks inevitably classify and have internal **models** of their worlds" (Ibid).

2270

NETWORK (Psychosomatic)

→ Psychosomatic network

2271

NETWORK (Random)²⁾

It has been defined as a network in which all **nodes** have about the same number of **links**. However, G. PASK quite to the point, wrote as early as 1961: "I do not condone a lot of loose talk about 'random networks'. Random network should mean a very definite initial **structure** determined by a random number table, presumably because the initial **structure** does not affect those features of **behaviour** that interest us, providing the **behaviour** is averaged over an ensemble of artifacts" (1961, p.84).

A fully random network should not present any **constraint** at all and thus be totally unpredictable, even in the statistical sense of a **Markovian system**. Such a network could not learn, not lead to any **organizational closure**... and, after all, could not be a network at all.

Practically however, **randomness** is always framed within some determining **constraints**.

2272

NETWORK RESILIENCE

→ Resilience in Networks

2273

NETWORK (Scale -Free)²⁾

A network with many **nodes** with few **links** and a few nodes with many links.

→ Scale-free networks

2274

NETWORKING⁴⁾

The spontaneous **coordination** between **groups** realizing different tasks in a **society** or **organization**.

It has been observed in insect societies (ants, termites or bees) that different **activities**, needed for the global **survival** of the society, become automatically harmonized. When needed, individuals may and do shift from one specialized **group** to another, through a *spontaneous process* of tasks allocation.

Such **patterns** also vary according to the maturity of the society, i.e. tend to stabilize when it reaches **dynamic stability**. See for ex. D. GORDON (1995, p.50-57).

Networking **adjustment** is also quite obvious in human **organizations**, especially in time of **strain**.

2275

NETWORKS AS IMPERFECTLY CONNECTED SYSTEMS²⁾

No working network could be totally and perfectly connected. It cannot be functional without a (limited) degree of leeway, or laxness. As said in terms of popular common sense: "All roads lead to Rome"(or anywhere else, or nowhere in particular)

In such a condition of indefiniteness the network is indetermined and cannot be usefully put to work.

And of course, if there are no **connections** at all between the **elements**, the network does not exist as such.

To become functional it must must acquire a more or less defined **dynamic organization**

It becomes partly determined in such a way when **rules** are introduced, defining a more or less wide variety of possible, but conditional **transitions**, together with other rules defining an **adaptive dynamics** (for ex. **parallel distributed processing**)

On the other hand, the specific conditions of **space** and **time** of the network limit the possible reaches of the rules.

→ **Ecosystems dynamics; Graphs; Homeostat; Inter-influences; Isochronic; Isotropy; Markovian system; Multistat-Network (Parallel Processing); Stability (Poly-); Synaptic weight**

2276

NETWORKS ORDERING²⁾

Networks are, by definition, sets of a number of **elements** and their **interconnections**. This is amenable to factorial **combinatorics**.

When the elements are very few, the number of all possible interconnections is quite limited. For ex., 3 elements can combine in $1 \times 2 \times 3 = 6$ different ways (AB - BA - AC - CA - BC - CB).

However, when elements become more numerous, the number of possible combinations grows inordinately. For ex. for 8 elements, we have

$1 \times 2 \times 3 \times 4 \times 5 \times 6 \times 7 \times 8 = 40.320$ ones. If all these interconnections - or corresponding **interactions** - are admitted, the net loses any specific definition and the number of operations gets out of **control**.

A natural solution is to introduce **constraints** (ASHBY, 1958, 1960 - GREY WALTER, 1953, p.27-28). This can be done:

- by creating a **meta-** (or **hierarchical**) **level** in the network in order to define a reduced number of "blocks" grouping a number of elements with a common **positional value** characteristic of the "block". For ex. A, B and C form a group L; D, E, and F form the group M and G and H form the group N. In this way the interconnection and **communication** problem is again reduced to factorial 3. The **process** can be repeated by creating **meta-meta-levels** and so on.
- by cutting some **links** between some elements., for ex. inhibiting direct **communication** between C and G, between A and F, etc... In this way, the network needs no hierarchical **nodes**. But it needs those constraining **rules**, that must be somehow stated or imposed.

both devices could moreover coexist. This seems for ex. to be the case for the neuronal network in the **brain**. Not all **connections** are possible or effective, and more or less specialized centers of **activity** shape up.

Obviously, **hierarchical** meta-levels signal the **emergence** of increased **complexity**. Meanwhile **inhibition rules** have somehow equivalent effects as hierarchization, with some more leeway. Ashby reformulated these **interconnections rules**, speaking of **richly** or **poorly joined** systems.

2277

NEURAL COMPUTATION^{2) - 3) - 4)}

"The construction of **invariances** by means of neural **mechanisms**" (St. KATZ, 1976, p.44).

St. KATZ adds: "When these **invariances** are assigned a name and given significance or **meaning** within some framework, they become what POWERS calls "controlled quantities" (Ibid).

In other words, the **neural network** constructs its **algorithms**, through its own activity. In psychology, POWERS field, neural computation may be redefined "... as a constructive **activity** occurring *within the subject*" (Ibid).

KATZ observes that the **subject** "... may attach **ontological** significance to the items it knows, (but) those who see the **subject-environment relation** within the framework of neural computation believe differently" (Ibid).

Neural computation can be considered as the root of **connectionism**. G. FERRY writes: "The connectionists...believe that systems can be developed, which, if connected together and endowed with sufficient **complexity**, will automatically process **information** and manipulate

knowledge. Connectionists are strongly influenced by biological systems. These biological **models** give hints about how **information** is stored and then processed in the **brain**". G. FERRY traces back this idea to D. HEBB views about the weighed **flexibility** of neurons **connections** with their neighbours and the **reinforcement** of pathways by continuous use (1986, p.36).

The basics of neural computation could introduce a new concept of **Artificial Intelligence**, not anymore relying on strict **preprogramming**, but based on progressive **training** through numerous examples of **objects** or **processes**, i.e. closer to natural intelligence.

2278

NEURAL NETWORK²⁾

"An array of **processors** interlinked by **connections** that can be strengthened or weakened" (H. COLLINS, 1992, p.40).

(Different types of similarly constructed networks are also known as **connectionist models** or **machines**, artificial neural systems or **distributing parallel processors**)

P. DENNING explains: "Neural networks are **structures** consisting of highly interconnected elementary computational units. The networks **map input patterns**, are encoded as vectors of **bits**, into **output patterns**. They are called *neurons* not because they **model** the nervous systems of animals but because they were inspired by them. Most authors do not emphasize the biological **metaphor**: they talk of units and **connections** rather than neurons and synapses" (1992b, p.426).

R. ROSEN offers the following short synthesis about the origins of neural networks **models**: "They were initially introduced by McCULLOCH and PITTS in 1943, as discrete, **Boolean** versions of the continuous-time dynamical network introduced earlier by RASHEVSKY (1960, p.230-41) and his collaborators. Technically the passage to **discrete time** served to sidestep the then insuperable analytical problems arising from the systems of **nonlinear** differential equations which characterize the continuous-time case: the study of neural **nets** requires only algebra and **combinatorics**. It quickly became clear that the neural networks not only furnished key insights into the **operation** of the **brain**, but also indicated how one might fabricate new systems which could behave in a brainlike fashion. Consequently, neural networks became one of the primary motivations of the theory of **automata** in all of its ramifications, especially in computation" (1979, p.181).

As to the **operation** of the **brain** W.J. FREEMAN (1975), (as quoted by S. GOONATILAKE, 1991, p.20) showed that "collectivities of nerve cells up to the **level** of ten million nerves ... have been studied as **dissipative structures** and shown to be **self-organizing** with **autopoietic** properties".

Presently, the analogy between neural networks (biological) and massively **parallel computers** (constructed **artifacts** assimilated to neural networks from a functional viewpoint) works in both directions.

S. STROGATZ and I. STEWART make the following and suggestive comment: "Neurons often act as **oscillators** and so, if central **pattern generators** exist, it is reasonable to expect their **dynamics** to resemble those of an **oscillator network**" (1993, p.73).

COLLINS, in turn, states: "...the concept takes its inspiration from the interconnected neurons of the **brain**. A neural network is "trained" by being given a series of examples of correct **responses** and the **connections** between its **processors** are strengthened or weakened according to its success of reproducing what is wanted".

... and "The neural network is never given an explicit body of **rules** to follow" (1992, p.40).

In other words, a neural network, is **trainable**. It does not receive an **algorithmic program** and its **behavior** is not precisely specified, nor standardised. It "learns", i.e. acquires **patterns of activities**, by progressive **adjustment** of **connections** between **inputs** and **outputs** through **feedbacks** and "**synaptic weighing**". It must not however present a completely **random behavior** if it is to reach some operative **state**: no *rigidly deterministic body of rules* does in effect mean no **rules** at all, since networks generally become functional through **Boolean switching functions** of either the type AND or the type OR.

D. GREENWOOD enumerates the following advantages in **information processing** by neural networks:

"1) **Information** learned by a network (i.e., stored in network **memory**) can be, as in biological systems, very tolerant to hardware failure and can be insensitive to arithmetic rounding problems...

"2) Existing network **learning methods** can circumvent the ordinary difficult problem of **programming parallel processors**. Networks learn by example and computer **algorithms** often are not required.

"3) **Pattern recognition** can occur in **parallel** and **patterns** with missing or distorted **components** can be completed.

"4) Feature extraction or **abstraction** can result as a by-product of the network **learning process** or from specially configured "competitive" networks.

"5) Neural networks can perceive and recognize spatial and/or temporal **patterns** in the presence of **noise** and with distortion. They also can process **discrete** or **continuous data**.

"6) **Hierarchies** of **data structures** can be represented as **layers** in a multilayer network.

"7) Conflicting aspects of **information** can be accommodated through network **self-organization**. Competing hypotheses can be represented, evaluated and selected in one network.

"8) Neural network classifiers can be non-**parametric** and make relatively weak assumptions concerning the shapes of underlying probability **density functions** compared to traditional statistical classifiers. Networks can learn multidimensional probability **density functions**.

"9) Networks can act as **controllers** in **environments** with several **constraints**" (1991, p.3).

Most of the former objections to **perceptrons** by M. MINSKY and S. PAPERT have thus been overcome.

However, D GERNERT observed recently that: "... the neural network still associate an **output pattern** to any given **input pattern**, such as the neural network itself can be considered a **model** of the original system. In a lot of practical applications this idea works with sufficient precision" (1994, p.128). But: "As far as can be seen presently, implicit **models** in neural networks do not open a way toward explicit **understanding**. A network can be prepared such as all internal weights and connection strengths at a certain instant can be measured, but such **data** offer no chance of an interpretation - no **rules**, **correlations**, or similar elements of our customary explicit **models** can be derived.

"Even worse, implicit **models** remain valid only as long as the conditions of their formation persist... Unfortunately... very often, the **decay** of such **models** creeps up slowly and unnoticed" (p.129).

It also seems probable that neural networks are submitted globally to **power laws**.

Neural networks are now much more that a kind of **metaphor** or abstract **model**.

D. FLOREANO writes: "by neural networks, it must of course be understood "nets of artificial neurons". These can be materialised either as electronic **components**, or computer simulated"(2002, p. 24)

FLOREANO and his team at the Federal Polytechnic School in Lausanne, Switzerland, have in fact created a real mobile mini-robot (**Khepera**) equipped with two wheels, eight luminous devices observing its **environment** and contacts conceived for spontaneous **connection** with electrical sockets when the robot is in need of **energy**.

Khepera's incorporated neural network is made of electronic components that may become interconnected in different ways, receiving any emitting **signals**, and transmitting them in a way similar to the **behavior** of biological neurons (2002, p. 24-26)

→ **Automata nets, von NEUMANN's architecture**

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

2279

NEURAL REPRESENTATION MODEL¹⁾⁽²⁾⁽⁵⁾

A device - formerly known as Wisard, and later Magnus - constructed by Prof. I. ALEKSANDER of Imperial College, London.

It was originally a "neural **pattern recognition machine**, an intelligent machine without a mind, just a layer of **neurons** which took a pattern in and labelled it".

Professor ALEKSANDER 's final goal is to modelize and study **consciousness**, as he goes on improving his **machine**. (2000, p.42-45).

This work is clearly related to so-called "**Artificial life**".

2280

NEUROCYBERNETIC PERSPECTIVE^{3) - 4)}

"A **metaphor** that emphasises active **learning** and **control** rather than the passive **adaptation** that characterises the "**open system**" view (R.L. FLOOD and M.C. JACKSON, 1991, p.10).

These authors stresses the interest of this view for **management** and **organisation** theory. They compare the positive and negative aspects of the same:

"Useful

"- It promotes self-inquiry and self-criticism and therefore the possibility of dynamic **goal-seeking** based on **learning**

"- When there is a high degree of **uncertainty** it encourages **creativity**

"When and why does it break down in practice:

"- It tends to forget that the **purposes** of the **parts** may not always be the same as the **purposes** of the **whole**

"- Adopting recommendations based on this **metaphor** would require most extant **organisations** to undergo significant **changes** that would threaten those that are favoured by the status quo; so they will be resisted

"- It neglects to recognise that **organisations** are socially constructed **phenomena**" (p.11)

As to this last point, it seems however that the neurocybernetic **model** could also help to reach a better **understanding** of social **constructs**.

2281

NEURODE²⁾⁽⁵⁾

A local processing **node** in an artificial **network**.

Neurodes have been inspired by **neurons** in biological (**neuronal**) **networks**. Accordingly, they have many incoming **connections** from other neurodes in the **network**, but emit only one outgoing **signal**, as the product of a single computing operation. The neurode thus executes a **transfer function**.

2282

NEUROMIME^{2) - 3) - 5)}

A "synthetic system which can generate and propagate an **action potential**, and hence exhibit excitability" (R. ROSEN, 1979, p.181).

ROSEN comments: "... the relation between such **model** systems and their biological prototypes cannot reside in any identity at the particular **level**, but must reside in common functional or relational properties which are preserved **invariant** when we replace the prototype by the **model**. Thus the wide employment of **model** systems already reveals the tacit recognition of analytic alternatives to **reductionism**" (Ibid).

2283

NEUROMORPHIC ENGINEERING⁵⁾

A new technology aiming at creating chips modelled in accordance with **brain structures** (Economist, sept.22, 2001, p. 24)

Neuromorphic engineers construct devices that contain **elements** functionally equivalent to **neurons**, axons and even "a primitive rendition of brain chemistry" (p. 24)

These devices are **analog machines**, not digital ones, and their **output** is a **behavior**, not a logical calculus.

The Economist's reviewer writes: "What neuromorphic engineering seeks to do is to build tools that think for themselves- making **decisions** the way humans do"

Besides this somewhat anthropomorphic way to express the idea, the reviewer adds: "...the neuromorphic approach may be the only way of achieving the (elusive) goal to build efficient "**adaptive intelligent control systems**..."

It would rather seem that this technique is leading to active and **autonomous self-organizing** electronic systems

The subject is closely related to so-called **artificial life**.

→ **Parallel Distributed Processing**

FIG

2284

NEURON¹⁾⁽⁵⁾

A cell of nerve tissue whose parts are a nucleus, afferent **receptors** and an efferent axon.

Neurons communicate with each others through intervals called **synapses** (where complex biochemical exchanges take place), and within very intricate **networks**, particularly in the **neocortex**, the most organized part of the human **brain**.

C. KOCH and G. LAURENT state: "Exquisite molecular machines endow neurons with complex **nonlinear dynamical** properties, regardless of the animal's size or evolutionary lineage. Moreover, these properties are not static, but adaptively tunable" (1999, p.97).

see figure above

→ **Brain; Brain circuit; Brain metaphor**

2285

NEURON (Formal)²⁾

Model of the biological neuron made up by a binary **element** whose state is +1 (active) or -1 (inactive). (L. PERSONNAZ et al., 1988, p.1364).

These authors explain: "It was conceived by W. McCULLOCH and W. PITTS, from Chicago University in 1943... It updates its **state** periodically in the following way: It computes the sum of its **inputs** (which are the **outputs** of the formal neurons to which it is connected). The value of every **input** being modulated by the corresponding synaptic **efficiency**, it takes a decision by comparing this sum with a **threshold** of its own. If the sum is superior to the **threshold**, the neuron adopt its active **state** (+1); in the opposite case, it remains in its inactive **state** (-1)" (Ibid).

The formal neuron is thus a totalizer of impulses, combined with a simple **binary decider**, or an "**all or nothing**" model, as stated by H.von FOERSTER (1981, p.33).

(For more precise and detailed description and comments of this important **model**, see H.von FOERSTER, 1981, p.33-42)

→ **Parallel Distributed Processing**

2286

NEXUS²⁾

The link or links existing between the **elements** of a **network**.

Also sometimes referred to as "plex" or "plexus".

Generally, **systemics** and **cybernetics** study nexus (plural). The term "nexialism", for the study of complex, unexpected and supposedly unmanageable situations, was even proposed in 1952 by A.VAN VOGT in his science fiction novel "The Voyage of Space Beagle" (thus introducing this compiler first to KORZYBSKI's **General Semantics** and later on, to the Society for General Systems Research!)

2287

NICHE^{1) - 2)}

"That **part** of the actual **environment** relevant to the unit's **survival** (i.e. its continued **organizational closure** without **desintegration**) (R. HARNDEN, 1990, p.299). He writes: "... niche has to be separated out from **environment** in the same **process** that structured **mechanisms** relevant to **survival** become visible in terms of the **observer**... The first step in handling any **complexity** is to reduce the general **noise** of the total **environment**. Indeed, that is precisely how perceptual and **cognitive processes** function (e.g. **Gestalt**)" (p.300).

In short, the niche is the specific sector in the general **environment** wherefrom the basic **determinisms** of the system do emerge. J.J. GIBSON distinguishes clearly "**habitat**", from "**niche**": "A niche refers more to *how* an animal lives than to *where* it lives. I suggest that a niche is a set of **affordances**" (1986, p.128).

In a more specific way and, somewhat surprisingly, giving to the term quite an active sense, the UNESCO - UNEP "Glossary of environmental education terms" defines the ecological niche as follows: "The role, status and position of a species in the **environment**, its **activities** and relationships to the biotic and abiotic **environment**" (1983, p.9).

S. MARTINEZ observes: "... what is important is the extent to which any *growth* niche is linked and in what ways to others by invasion, exchange, or incorporation, perhaps even a **random encounter**" (1993, p.401).

Niches are not static since its occupants - plants, animals and also human **populations**, trades, products, techniques or concepts - cross-fertilize, evolve and co-evolve.

Clearly, "**niche**" is more an ethological than an ecological concept, even if both are interdependent.

2288

NICHE (Empty)²⁾

A potentially useful, but unoccupied part in an **environment**.

In an ecological environment, such empty niches may appear after important **perturbations**, as for example a cyclone, a bush or forest fire, or on new alluvial islands in a delta.

In human **activities** many unoccupied or underoccupied parts of all continents were once empty niches, apt for colonization.

Technical innovations are also frequently creating new empty niches in economic activities. The whole sector of electronics and computation is an impressive example.

2289

NK MODEL²⁾

A formal model of "rugged **fitness landscapes**".

This model has been introduced by S. KAUFFMAN to represent the internal **constraints** of a **complex system**. "In this model, *N* refers to the number of **parts** of a system - genes in a genotype, amino acids in a protein, or otherwise. Each **part** marks a **fitness** contribution which depends upon that **part** and upon *K* other **parts** among the *N*. That is, *K* reflects how richly cross-coupled the system is... *K* measures the richness of epistatic **interactions** among the **components** of the system" (1993, p.40).

KAUFFMAN's development and uses of his model (in genetics) are quite technical, but the model seems to be potentially very general.

An interesting development about this type of model, related to evolutive **fitness landscapes** can be found in P. BAK's 1996 book "How Nature Works" (p.118-27).

These models are also known as NKC models, *C* being the number of **couplings** between some particular trait in various interacting species.

→ **Co-evolution; Red Queen Evolutive parable**

2290

NODAL ACTIVITY^{2) - 4)}

The specific **processes** that take place at some defined points within a **network**.

The concept has been proposed by the sociologist A. STINCHCOMBE (1968, Ch.VI). This author, considering commercial and economic activities, emphasizes the existence of critical "**connections spots**", where some specific **operations**, mostly related to transportation and communication, are done in a better and easier way.

Obviously, the need for efficiency in the displacement or any kind of commodities or **knowledge** within a system (existing or self-organizing) tends to favour nodal activity. The nodal activity model appears in the works on **hexagonal space filling** of W. CHRISTALLER (1933; 1937) and A. LÖSCH (1944; 1954).

It also permeates the works of the French historian F. BRAUDEL (1982), who shows the successive **nodes** of commercial and financial **activity** in Western Europe from the 16th to the 18th century: Venice, Antwerp, Rotterdam, London, etc.

The concept is clearly related to the **neural networks models**.

2291

NODE^{1) - 2)}

A connected spot or **element** in a **graph** or in a **network**.

Atoms in a complex molecule, words in a **language**, people in an **organization** and generally any **elements** more or less selectively **interconnected** with others, become nodes, i.e. add **positional values** to their proper nature.

H.M. PAYNTER thus explains the properties of the nodes: "Most generally they might be unlabeled and therefore uniform and undistinguishable. However, in any **directed graph**, some of the **branches** incident on a given node will be directed toward it, others away. But it will always be observed that for unlimited richness of **structure** all **graph** systems must have at least one (type of) node with three or more **branches**, and that if the **graph** is **directed**, at least two **branches** must be directed toward this node. Moreover, as the American philosopher and logician C. S. PEIRCE discovered

nearly a century ago, but one **triadic node**-type, with two **in-branches** and one **out-branch** is necessary for infinite **variety of structure**" (1968, p.76).

→ "Node (Triadic)"

This node **model** does now appear as absolutely fundamental for the understanding of **neural nets**, which in turn are basic **models** for any interpretation of **complex systems** formed by numerous interacting **elements** (each of which can be considered a node). On the other hand, PEIRCE'S **model**, which is the most elemental summation device, anticipated, for instance, the Mac CULLOCH-PITTS neural transmission **model**.

Complexity of **networks** grows factorially in relation to the number of their nodes and the **connexions** between these.

2292

NODE (Critical)^{1) - 2)}

A node whose suppression in a **network** impairs its functionality.

Impairment can be partial or complete, temporary or definitive. Generally, subtracting (or adding) a node in a **network** may implicitly affect the whole **network**, but not necessarily in a critical way. Three main possibilities exist:

- The **change** produces the **network's** destruction;
- A progressive **damping** absorbs the modification;
- the **change** triggers the **emergence** of a **network** on a higher level of **complexity**

Redundancy in the **network** may allow for its sufficient reorganization in case of partial destruction. Examples are the spontaneous reordering of the **brain** after a non-fatal cerebral haemorrhage, or of a military unit after a rout.

2293

NODE (Triadic)²⁾

A node "... with two **in-branches** and one **out-branch**" (H. PAYNTER, 1968, p.76).

The **concept** of triadic node was introduced by C. S. PEIRCE.

H. PAYNTER emphasizes: "At the level of **binary logic**, PEIRCE himself anticipated SCHEFFER in the discovery of the alternate denial and joint denial **operators** (the modern NOR and NAND)... A universal triad must be both associative/dissociative and symmetric with respect to **in-branches**" (p.77).

2294

NOISE¹⁾

A **random** non-rhythmic **disturbance** in a communication **channel**" (J.Z. YOUNG, 1978, p. 296)

"The perturbing **part** in a temporal **signal**" (R. VALLÉE, 1992).

or, with more detail: An environmental **disturbance** which reduces the **reliability** of the **message** transmitted through the **communication channel**.

VALLÉE's definition gives the general sense of the term, not merely the technical one.

The noise is the part of the **signal** which is not understood, or seems still senseless. VALLÉE states that the complete **signal** is the sum of its significant and non-significant **parts**.

About the concept of "**order from noise**", he writes: "Noise does not create **order**, but it is an excellent developer (in the photographic sense) of **structure**... It can also, through the **fluctuations** that it provokes, become a "**structure trigger**" (Ibid).

This is **nucleation** in conditions of **dissipative structuration**.

Other interesting comments about noise are:

"All that is not **information**, not **redundancy**, not **form** and not restraint – is noise, the only possible **source** of **new patterns**" (G. BATESON, 1973, p.386)

"... in my restaurant, **self-organizing systems** do not only feed upon **order**: they will also find noise on the menu" (H.von FOERSTER, 1981, p.15).

"It is not bad to have noise in the system. If a system freezes in a specific **state**, it cannot anymore adapt, while this final **state** may easily be faulty and it will not be able to adapt to anything that would be an inadequate **situation**" (H. ATLAN, 1972, p.24, quoting von FOERSTER, 1960, p. 31-50)

According to C. ZIMMER (1999, p. 86) "**non-linear dynamics** seems to amplify noise"

Apparently, the significance of noise is deeply modified in **deterministic chaos**.

It becomes either enhancing and constructive, or on the contrary destructive, in particular in relation to some peculiar conjunction of environmental conditions acting as **amplificator** or **constraints**.

2295

NOISE GENERATOR^{1) - 2)}

Any **source** which produces an unpredicted sequence of **events**.

D. MacKAY considers the case of the noise generator as **information** producer in these terms:

"a) A noise generator... is a **source** not primarily of **information** but, if we must call it a **source** of something, simply of surprise

"b) it becomes a **source** of **information** if and insofar as it leads to representational **activity**, and its "**output of information**" is to be measured relatively to the ensemble of **representations** on which it evokes selective **operations**

"c) a **source** does not, however, produce significant **information** unless the representational **activity** evoked has significance for some **receiver**" (1969, p.137).

Further on, Mac Kay states: "... a noise generator can be regarded as a **source** of completely original, but **meaningless information**" (p.137).

2296

NOISE in a channel⁵⁾

Any **random disturbance** originated in the **environment** which reduces the **reliability** of a **message transmission** in a **communication channel**.

SHANNON'S so-called 10th Theorem states: "If noise appears in a **message**, the amount of noise that can be removed by a correction channel is limited to the amount of **information** that can be carried by the channel

This is quite similar to ASHBY'S "**Law of Requisite Variety**"

Many practical examples are well known, for example in radio, T.V., telephone, fax, etc... **transmission**.

K. KRIPPENDORFF comments: "The **analogy** between noise and **thermodynamic entropy** is suggested by the fact that in any **communication process**, noise can only increase and it does so at the expense of the amount of **information** transmitted from a sender to one or more **receivers**" (1986, p.53).

In some cases, noise **disturbances** may endanger the functional **reliability** of **parts** or even the **whole** of a system: a lightning may put an electric circuit out of order, or a jumbled **message** may impair some critical **action**.

R.L. ACKOFF and F.E. EMERY distinguish **semantic**, **syntactic** and pragmatic noise. On this last they write: "Pragmatic noise (is) anything that appears in a **message** or its **environment** that was not produced by the sender and decreases the probability of the **receiver's** responding in the way intended by the sender" (1972, p.182).

T.F.H. ALLEN and T.B. STARR go further and define noise as "Any aspect of a **signal** string which is not considered significant" (1982, p.274)

Or: "That part of the **signal** which is not considered to be associated with **meaning** for the **purpose** at hand" (Ibid).

The word "considered" introduce (rightly) a doubt, as in this case, either the sender, or the **receiver** – or both – may well miss something significant in the **message** only because they do not *consider* it – or simply do not understand it – to be significant!

It must however be admitted that "significance" is a characteristic of the **observer**, which moreover, may subtly depend on her/his interpretative ability. BECQUEREL'S veiled photographic plates where spoiled by "noise", until he did understand the **correlation** with the (radioactive) samples that he had stored in the same drawer, without noticing their peculiar **behavior**.

2297

NOISE in a SYSTEM²⁾

A **perturbation** "which interferes with the otherwise **deterministic behavior** either additively, or through some of the **parameters** characterizing the system" (G. NICOLIS and I. PRIGOGINE, 1978, p.30).

Such a noise can generate an **oscillation** that can be **damped**, or lead to the destruction of the system, or play a critical role to orient **dissipative structuration** at a **bifurcation point**.

From this viewpoint, and according to G. BATESON, quoted by E. MORIN, anything which is neither **information**, nor **redundancy**, nor **form**, nor **constraint** is noise. (1972). However BATESON considers that noise is the only possible **source of new patterns**.

This view is expressed by H.von FOERSTER in this way: "Thus in my restaurant, **self-organizing** systems do not only feed upon **order**, they will also find noise on the menu" (1960, p.31). H. ATLAN puts it as follows: "It is not bad to have noise in the system. If a system freezes in a specific **state**, it becomes unadaptable and the final **state** may easily be faulty. It will not be able to adapt to anything that would be an inadequate **situation**" (1972, p.24).

While this is acceptable, let us remember that too much is too much! ...and that it may be difficult to know when a critical **threshold** of noise is too close for security.

Noise can also be generated within the system, which possesses internal **communication channels**. This is doubtless the case in biological and in **social systems**.

2298

NOISE (Sensibility to)¹⁾

As systems become more complex, their capacity to perceive become more differentiated, and they register more **signals** originated in their **environment**.

Some of these **signals** are immediately significant, because similar **signals** were previously incorporated to meaning **sets** already organized within the system.

Others are not and must be considered as noise. Complex systems, when registering noise in increasing quantity and diversity, can survive only by enhancing their capacity to create **complexity** in their internal **representations**, i.e. by assimilating these noises in a significant way. How this is done is not yet very clear. However this process seems indeed to be a very general trend in **evolution** and may even be the cause of what F. MEYER described as **evolutive acceleration** (1954)

→ "Order from noise"; "order parameter".

2299

NOMINAL GROUP TECHNIQUE

→ **Group Technique (Nominal)**

2300

NOMOGENESIS²⁾³⁾⁵⁾

"Directed increase of **complexity** (pre-adaptation) and immediate effect of the **environment**" (as defined by V.V. NALIMOV, 1985, p. 32)

Nalimov relates nomogenesis to **Bayesian probabilities**: "The Bayesian syllogism, in accordance with Nomogenesis, ignores the creative role of **natural selection**. However, what we keep in mind is not complete rejection of natural selection as a factor of **evolution**, but the abandonment of the concept of evolution as a **random search**" (Ibid)

It seems obvious that evolution, i.e. any kind of evolution, must necessarily be a compromise between **processes** and **structures** that self-constructed as results of **constraints** in the past (but still in force) and the possibility or need for innovation.

It would be interesting to compare these views with the concept of **deterministic chaos** and **self organization**.

→ **Artificial life; Co-evolution; Morphic field; Neoteny; Network behavior; Parallel distributed processing**

2301

NON-, NO-³⁾

The French philosopher G. BACHELARD, in his "Philosophie du non" (1949), was one of the very firsts to state clearly the progressive but unavoidable escape of most sciences from the limits of the aristotelic and mechanistic thinking. He emphasized the importance of **connections** and **complementarity** (as for example in HEISENBERG's **indeterminacy**) as leading to the need for "non-analyticity". He also discussed KORZYBSKI's non-aristotelician logic (1933) and O.L. REISER's "Non-aristotelician logic and the crisis in science" (1937). This led him to extol the synthetic value of no-, or non-positions in the sciences, meaning a general conceptual extension outside the boundaries of classical **reductionist** ones, but without excluding these latter.

We are now able to better understand his proposals, for an inductive and synthetic **epistemology**, after the discovery of non-newtonian **dynamics**, **non-equilibrium** chemistry, **non-homeostatic** systems, **nonlinear** and **non-deterministic** macrosystems (i.e. **chaotic determinism**) (all of these already preceded by non-euclidian geometries during the 19th century!).

→ **Non-Principles**

2302

NON - PRINCIPLES^{2) - 3)}

The French biologist H. PRAT made a census of a number of negative principles which contributed or could contribute to open new horizons to 20th (and 21st) Century sciences:

"1. Principle of non-identity: In experimental sciences, identity does not exist (two **objects** or **elements** can never be identical). ... A mitosis, for example, is never strictly equational. Ignoring this fact led to many persistent errors in the interpretation of animal and vegetal organogenesis".

"2. Principle of non-repetition: As the **set** of causes corresponding to an experience A can never be identically reproduced in an experience B, only a more or less great probability can exist for **confirmation** in B of the results obtained in A; but never an absolute certainty. The probability increases with the number of concurring experiences, but never becomes infinite".

"3. Principle of non-extrapolation: All laws and concepts that we formulate are only valid within given **limits**: those accessible to our **observations on space, time energy, information scales**. Beyond these **limits** we should not extrapolate".

"4. Principle of non-independence: All **elements** and **parameters** in the universe are interdependent. Any modification of one, modifies in some measure (big or small) all the others".

"5. Principle of non-constancy: In the universe, nothing is absolute: there are no universal constants; nothing is totally **invariant**".

(This revolutionary statement leads its author to emphasize a totally abstracted formulation of $E = mc^2$, that should make it practically disembodied... and useless).

"6. Principle of non-limitation: No **limit** may be imposed to any **magnitude** in the universe, which is limitless in all the hyper-space scales: **space, time, matter, energy and information**" (1968, p.3-4).

While these ideas should be taken "cum grano salis", as "food for thought", it should be noted that other non-principles were formulated by HEISENBERG and EINSTEIN, as well as by the **non-aristotelician** Polish-American logician A. KORZYBSKI, the Austrian mathematician K. GÖDEL and the French philosopher G. BACHELARD... not forgetting PRIGOGINE's **non-equilibrium thermodynamics**. They are undoubtedly present in systemics, where "the **whole** is *not* merely the sum of the **parts**" and in cybernetics, where **causality** is *not* anymore **lineal**.

Somehow, non-principles are related to **complexity**, as we finally met it in our minds.

→ **NO-, NON**

2303

NON-ARISTOTELICIAN THINKING^{3) - 4)}

A. KORZYBSKI, who introduced what he called non-aristotelician thinking wrote: "The... non-aristotelician system is based on fundamental **negative** premises; namely, the complete denial of "identity", which denial *cannot be denied* without imposing the burden of impossible

¹⁾general information²⁾methodology or model³⁾epistemology, ontology and semantics⁴⁾human sciences⁵⁾discipline oriented

proof on the person who denies the denial. If we start, for instance, with a statement that 'a word is *not* the **object** spoken about', and someone tries to deny that, he would have to produce an actual physical **object** which would *be the word*... This general denial of the 'is' identity gives the main fundamental non-aristotelician premise... The status of negative premises is much more important and secure to start with than that of the positive 'is' of identity, found in the aristotelician system, but easily shown to be false, and involving important delusional factors.

"Any **map** or **language**, to be of maximum usefulness, should, in **structure** be similar to the **structure** of the empirical world. Likewise, from the point of view of a theory of sanity, any system of **language** should, in **structure**, be similar to the **structure** of our nervous system. It is easily shown that the aristotelician system differs structurally from these minimal requirements, and that the non-aristotelician system is in accordance with them.

"This fact turns out to be of psychophysiological importance." (1950, p. 10-11).

KORZYBSKI insistently recommends training in non-identification as a way to protect psychological and mental sanity and gives numerous practical ways to do it. He views abusive identification as the root of most psychological and socio-political problems.

→ See also: **map-territory relation; non-identity principle; self-reference; structural differential; time-binding.**

Autopoiesis and **organizational closure** are obviously non-aristotelician concepts. So are most modern scientific theories related to **complex systems**. (See "**Non – no**").

KORZYBSKI's fundamental work on non-aristotelician concepts is undoubtedly a corner stone for **general systemics**.

2304

NONEQUILIBRIUM¹⁾ – 2)

The condition of a system undergoing ever wider **fluctuations** until it reaches some critical **unstability threshold**.

The basic understanding of nonequilibrium evolved considerably in the recent years. Before, as stated by I. PRIGOGINE et al, it was "considered as a **perturbation** temporarily preventing the appearance of **structure** identified with the **order at equilibrium**" (1975, p.17).

However, as stated by I. PRIGOGINE "nonequilibrium may be a source of **order**" in its own right, through the mechanism of **dissipative structuration**" (1978, p.1/2).

Widely fluctuating systems, writes E. JANTSCH: "... try to maintain their capability for **energy** exchange with the **environment** by switching to a new dynamic **regime**" (1976, p.38).

This occurs through **dissipative structuration** and may lead to higher **organization**, in accordance with the principle of **order through fluctuation** established by I. PRIGOGINE. This higher internal **organization** of the system implies inevitably a higher **level of entropy** production.

N. ZELENY and N. PIERRE state: "Both nonequilibrium and **instability** are essential for **self-organization** of higher **complexity**" ...and by the way "Human systems **management** is **not** optimal **control** theory or theory of **conflict** resolution" (1976, p.164).

In the same vein, A. TAYLOR writes: "Nonequilibrium systems are characterized by a high degree of **energy** exchange with the **environment** (and can therefore be termed **dissipative structures**). Thus, nonequilibrium **dynamics** is moving toward a theory of **self-organization** of **processes** and **structures**, applicable not only to the physical but to the biological and social **domains** as well" (1976, p.176).

2305

NON-ERGODICITY¹⁾ – 2) – 4)

The characteristic of a non-strictly **deterministic** system which offers only **long-term** non-repetitive **behavior** to the **observer**.

According to K. KRIPPENDORFF this **situation** involves only "**transient states** which are unique,... or **transition** probabilities (that) are so variable that there are not enough **observations** available to ascertain them" (1986, p.53). While both types of **situations** are very different, they are practically undistinguishable in most cases.

And: "**Evolution** and **social processes** are inherently non-ergodic. To understand non-ergodic **behavior** requires either reference to the underlying **organization** of the system exhibiting it or the study of a large sample of systems of the same kind" (p.53).

The precise **limits of ergodicity** have been better defined by the use of LYAPOUNOV's **exponents** (in theoretical **modeling** at least). Moreover, the perspective on non-ergodicity is now modified by **chaos theory** and its reference to the oblivion of **initial states**, as well as by **dissipative structuration**.

As to **social systems**, their "**underlying organization**" is still quite enigmatic, even in terms of **networks**. It is also practically impossible to study "large samples of systems of the same kind". Non-ergodicity remains a great challenge for systemics.

2306

NON-IDENTITY PRINCIPLE²⁾ – 3) – 4)

This principle was quite graphically expressed by A. KORZYBSKI, when he stated that "The map is not the territory" (i.e.: the **label** is not the **object**, and **label** on **level 2** of **abstraction** is not to be confused with **label** on **level 1** nor

with **label** on **level 3**). The Belgian surrealist painter R. MAGRITTE who painted a pipe with the caption: "This is not a pipe", made the same point.

The non-identity principle is the only way out of the paradoxes provoked by **self-reference**, whose pernicious effects were described by A.N. WHITEHEAD and B. RUSSELL in their "Principia Mathematica" and further considered by H.von FOERSTER, who in turn inspired H. MATURANA in his work on **autopoiesis** and F. VARELA in his **calculus for self-reference**.

The non-identity principle leads also to a **recursivity** of expanding logical **layers**, as a result of GÖDEL's **incompleteness theorem** and is related to D. BOHM's concept of **generating order** (1987).

On psychological ground non-identity leads to non-identification, i.e. to avoid the identification fallacy, which, as shown by KORZYBSKI, opens the road toward mental illness.

2307

NON-INTEGRABILITY²⁾

Condition of a system "...characterized by a continuous spectrum and the presence of continuous **sets of resonances**" (I. PRIGOGINE et al, 1991, p.3).

Such systems are complex, having a number of interconnected **internal** conditions. In the authors words: "As is well known, non-integrability leads to the appearance of **random trajectories** and **chaos**" (Ibid).

This feature led recently the authors (in the referenced paper) to introduce an **internal time** in their classical and quantum mechanics **models** "... describing the **relations** (the "**correlations**") between the particles (Ibid).

The **internal time** – in a biological **context**, and based on empirical observations – was described in the thirties by the French biologist P. LECOMTE du NOÛY (1936).

2308

NONLINEAR²⁾

Character of a system whose **parameters** do not vary in arithmetic proportion.

This nonlinear character is generally ignored in many **models** because assumed **linearity** enormously simplifies **modeling** and produces simple solutions.

J.W. FORRESTER observed: "There has been a reluctance to give up the **linear** mathematical procedures, with the result that **models** have been biased to fit the **linear** procedures at the expense of faithfulness in representing the real world" ... and "Accepting nonlinearity tends to force a person out of the world of theorist into the world of the practitioner" (1973, p.104).

In effect, **linear** approximations become unreliable near nonlinear **thresholds**.

In A. McROBIE and M. THOMPSON words: "If we include the nonlinearities of the system in the analysis, then more than one **steady-state** solution is produced and the one on which the system settles will depend on its **initial conditions**" (1990, p.42).

2309

NONLINEAR DYNAMICS

→ **Dynamics (Chaotic); Dynamics (non linear)**

2310

NONLINEAR PARADIGM³⁾

L. DOUGLAS KIEL proposes to label in this way a **methodological** framework which already includes a **variety** of theories as for instance nonlinear **dynamics** and **chaos theory**. (1992, p.28).

He could add **self-organization in nonequilibrium systems** (PRIGOGINE et al); **networks** theory (RUMELHART and Mc CLELLAND); **catastrophes** theory (THOM and ZEEMAN); **synergetics** (HAKEN); **Hypercycles** theory (EIGEN); **fractals** (MANDELBROT) and possibly some more.

2311

NONLINEARITY^{1) - 2)}

Characteristic of a relation in which the **variable** is multiplied or divided by coefficients themselves **variable**.

"What comes out of a nonlinear equation isn't proportional to what goes in; unlike linear equations, they may contain **feedbacks** and **thresholds** and other features that can yield complicated results"(C. ZIMMER, 2000, p.84)

Some examples are: exponential, or **logistic**, or asymptotic **growth**, **cyclical variations** and **chaotic behavior**.

According to F. BAILLY, F. GAILL and R. MOSSERS, "Nonlinearity corresponds to the growing **complexification process** associated with **iteration**, as in **morphogenetic complexification**. A mere linear **iteration** would be purely additive and unable to account for a progressive, **structural** and **functional complexification**." (1991, p.58).

Any **iteration**, in order to lead to **complexity**, must go with the creation of specific **links**, i.e. restricted ones in relation to all the potentially possible ones, but still not merely additive.

L. DOUGLAS KIEL observes: "(their) **sensitivity to initial conditions** means that nonlinear systems are **historical systems**. Furthermore, nonlinear systems are a result of both **determinism** and **chance**. While the **history** of the system determines its **evolution**, the **element of chance**, ranging from the nature of external shocks to changing internal **dynamics**, plays an essential role in the **evolution** of the system" (1992, p.34).

This formulation seems somewhat ambiguous.

It should be clearer to say that, in the history of any system, pure **determinism** is perceived as having reigned until the present moment, because the system reached its present **state** through one and only one line of **transformations**, while more or less **chaotic determinism** becomes dominant into its future.

Moreover, while the term "**evolution**" is very frequently applied to the adaptive transformations of systems, this use is questionable: *Individual* systems do not undergo **evolution**, but merely some occasional **mutation**, which becomes immediately fixed (*if* not lethal and *if* transmitted).

2312

NON-LOCALITY^{2) - 3)}

The boundless influence of an **element**, **event** or system in **space** and **time**.

The status of the concept – generalized by D. BOHM – is still somewhat obscure and controversial.

In BOHM's words, there is an "implicate **order**... This order is not to be understood solely in terms of a regular arrangement of *objects* (e.g., in rows) or as a regular arrangement of *events* (e.g., in a series). Rather, a *total order* is contained, in some *implicit* sense, in each region of **space** and **time**" (1980, p.149).

BOHM exemplifies this as follows: "Thus, in a television broadcast, the visual image is translated into a **time order**, which is 'carried' by the radio wave. Points that are near each other in the visual image are not necessarily near in the **order** of the radio **signal**. Thus the radio wave carries the visual image in an *implicate order*. The function of the **receiver** is then to *explicate* this **order**, i.e. to 'unfold' it in the form of a new visual image" (Ibid).

An **hologram** offers another insight in non-locality, as its **whole information** content is scattered in its **whole** extension.

I PRIGOGINE observes that some **transformations** are non-local as they replace "a point by an ensemble" and "break the temporal **symmetry**" (1986, p.10). This is an interesting clue.

The non-locality concept is somehow endorsed by H. SABELL: "In the language of **Process theory**, only the material **component** of a system is local, whereas the **energetic** and **informational** aspects irradiate boundlessly" (1992 b, p.682). It is debatable if this is exactly BOHM's idea.

If finally well confirmed, non-locality will very probably become a cornerstone for a cosmic generalization of **systemics**.

In the recent years, research on non-locality and the related **phenomena** of **entanglement** and decoherence in quantum mechanics has entered in its experimental phase.

However, particles behavior and the macroscopic world of classical mechanics remain still at odds for our common **understanding**.

As stated by S. HAROCHE in a paper explaining research in course: "The results of all these experiments are counter-intuitive"(1998, p. 36-42)

→ **Quantal representation; Quantum hologram; Quantum vacuum**

2313

NONSPECIFICITY^{2) - 3)}

A type of **uncertainty** brought about by the existence of a set of alternatives.

G. KLIR states: "Nonspecificity is exemplified by the HARTLEY measure in classical **set** theory: the greater the **set** of alternatives that are left undecided in a **situation** (e.g. **predictions** or prescriptions), the less specific the **situation** is; when only one alternative is possible, the **situation** is fully specified" (1991, p.118).

Nonspecificity can easily remain unrecognized in complex **situations**, leading to **under-conceptualization** (WARFIELD) and serious mistakes in diagnosis, **forecasts**, **design** and **planning**.

2314

NOOSPHERE^{1) - 4)}

"The sphere of **interrelations** between society and nature within the **limits** of which the wise human **activities** become the main factor of **development**" (UNE.1, p.19).

The definition from the "Glossary of environmental education terms" of UNESCO – UNEP seems optimistic.

While the existence of the noosphere is evermore evident and human intervention upon nature evermore intense, it is far from evident that it is always "wise" and that it leads finally to a **development** which is supposed to be **sustainable**.

A harmonious noosphere would need quite a better **understanding** by man of the **effects** of his interferences with natural **processes** now and in the future (specially at **long term**).

The word and concept was introduced by the well-known French Jesuit and paleontologist P. THEILARD de CHARDIN around 1950.

2315

NORM³⁾

1. A behavioral standard or **model** applicable to a specific **class** of systems.

Norms systems are practical **codes** for any type of transactions at a wide social **level**.

Norms translate **values** to the **level** of enacted **behavior**. They settle down as a **consensus** through repeated interactive **feedbacks** between users, because they permit a great economy of **resources** by avoiding uncertainties, incompatibilities, **conflicts**, and un-

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

necessary iterative experiences and **complexity**. They also increase the systems **predictability** and make it more easy, i.e. less costly, to maintain.

Hierarchies of norms may appear, as encompassing global norms are produced through the **interactions** of local and specific **needs** of systems entering a more global one. (e.g. European norms superseding national ones).

Norms may however need to evolve as for example technical ones. This is generally a difficult **process**, because they precisely are designed to enhance **stability**. As a result, there is a general tendency to cling to established norms and to resist new ones.

2. The most common **behavior** of a system, as defined by "normal" **distribution**.

This is a mathematical concept, which is in no way connected with the former one.

2316

NORMATIVE ETHICS

→ **Ethics (Normative)**

2317

"NOTHING BUT " FALLACY ¹⁾²⁾³⁾

The kind of superficial **analogy** that blocks the mind in a restricted and excluding **schema** about some **entity** or **issue**.

This fallacy was strongly denounced by K.L.von BERTALANFFY. An example is: "An **organism** is nothing but a **machine**". Vague analogies should be replaced by the **perception** and clear **understanding** of specific and limited **similarities**.

Even the term "**isomorphism**", proposed by Bertalanffy himself, should be used carefully. In fact any "isomorphic" model of an entity is no more than **homomorphic**. It represents merely some selected and seemingly significant aspects of the entity.

Only models of two or more different entities could be isomorphic models. A good example are the isomorphisms between levels in MILLER's **taxonomy of living systems**.

To avoid mere analogical fallacies, Bertalanffy resorted to mathematical expressions as far as possible. M. DAVIDSON, (quoted by M. MULEJ) wrote: "By using differential calculus, he was able to provide mathematical precision to such GST concepts as **dynamic equilibrium** (the **steady state**), the import of **energy** from the **environment** (**negentropy**), and self-restoration in response to external **disturbances** (**equifinality**)"

Topology is now also a source of precise **modelling** for isomorphisms in **processes**. Examples are **attractors** or **Poincaré sections**. Other useful precise models are **networks**, **power laws**, **renormalization transformations**.

Graphs and **matrixes** are also useful.

2318

NUCLEATION MECHANISM ^{1) - 2)}

A mechanism by which a new **structure** establishes itself first in a limited **region** and than invades the whole **space**.

According to G. NICOLIS and I. PRIGOGINE, the concept originates in physico-chemistry as "... the **phenomenon** of *nucleation* familiar from **equilibrium phase transitions**" (1977, p.323).

It appears when a system submitted to widening **fluctuations** becomes **unstable**, which leads to **dissipative structuration**. The new **structure** will be a more or less randomly result of the antagonism between the **instability** that tends to amplify the **fluctuation** and "the effect of the large outside **environment** in which **fluctuations** may be neglected. The outside world thus acts as a mean **field** that tends to **damp** the **fluctuations** through the **interactions** which occur on the **boundaries** of the **fluctuating region**... In the case of small size **fluctuations**, **boundary effects** will dominate and **fluctuations** will regress. On the contrary, for large scale **fluctuations**, **boundary effects** become negligible.

Between these limiting cases lies the actual **size** of nucleation. This is the reason why a general law of **fluctuations** independent of size, such as given by a **POISSON distribution**, is no longer valid" (PRIGOGINE et al., 1978, p.52).

The same mechanism is obviously present in **population genetics** and in technical innovation, for instance. P.P. GRASSÉ's **stigmergy** also is an example of a nucleation mechanism.

2319

NUCLEATION PRINCIPLE ^{2) - 4)}

"Any **structure** has a minimum **size**, which is its "**nucleus**" (K. BOULDING, 1956, p.70)...and "which results of a "mysterious initial act of nucleation" (p.71).

BOULDING states that the term comes originally from physics, but has a quite wider sense. He writes: "Once a **nucleus** has been formed, it is not too difficult to understand how **additions** to the **structure** are made. The formation of the **nucleus** itself, however, presents many problems which are quite different from those involved in the **growth** of an already established **structure**".

He gives the example of the crystal, whose minimal **nucleus** is, by necessity, an ordering of atoms which, as individuals are not crystals and cannot be a **nucleus**. He adds: "In the case of the **cell** the problem of nucleation is almost completely unsolved" (ibid).

On this matter, some important progress has been made since 1956. See: "**Autogenetic system precursor**"; "**Morphogenesis**".

BOULDING also points out that the same **phenomenon** appears under the guise of social innovators "those mysterious individuals who establish religions, cultures, nations, techniques and ideas" (ibid).

→ **Zero system**

2320

NUCLEUS (Original) ^{1) - 2)}

The minimal initial **structure** from and around which the system will construct itself by **replication** and, in many cases, by **differentiation**.

This concept was introduced by BOULDING in 1953, but until V. CSANYI's work (1989, 1993), it had never been duly scrutinized, at least in its systemic sense. The original nucleus seems to contain a kind of basic **algorithm** needed to guarantee the **autopoietic** future of the system, i.e. its permanent identity and **coherence**.

However, the potential of this **algorithm** does reveal itself by progressive **differentiation** and structuration through **interactions** of the system with its significant **environment** (which becomes also defined by the original nucleus).

In very **complex systems**, the potential of the **algorithm** is so enormous that it can never be completely expressed during the **life-time** of the system, which must make "**choices**" frequently and generally cannot retrocede to anterior forms of **organization**. These **choices** imply a progressive limitation of the virtual possibilities of the system. Such comments apply to individual personalities, **organizations** and cultures.

BOULDING also observes that the nucleus is generally some **heterogeneous element** or "impurity", wherever it appears. This seminal comment, in turn and unfortunately did never arouse much attention.

2321

NUMBER (Random)

→ **Random Number**

2322

NUMBERS (Law of Great) ²⁾

H. SIMON has stressed the importance of the Law of Great numbers as an **aggregation** tool, or **variety reductor**. He gives statistical mechanics as an example of this simplifying potential. By its use "it transforms the enormous **complexity** of a mechanical microsystem into the relative simplicity of **macroscopic thermodynamic** regularities.

"Through **stochastic processes**, we simplify the **description** of a **dynamic system's history** by ignoring temporal **trajectories** of its various **elements** and by considering solely their **distribution** among the **states** of the system and the **transference** probabilities from one **state** to another. Another important simplification is obtained by considering only the

equilibrium states of such systems, which can be frequently calculated without taking in account the **trajectories** used to reach these **states**" (1990, p.140).

2323

NUMBERS (Prime) ^{1) - 2)}

As **incommensurability** in conjugated **periodic processes** in a system seems to be a condition for **chaotic behavior** (P. BERGÉ and M. DUBOIS, 1992, p.120), it also seems that the **interrelations** between prime numbers are a basic subagent factor of **complex systems organization**.

Non-ergodic behavior in **complex systems** with a superposition of **processes** of different **periodicity** could be related to prime numbers.

If the various **periodicities** are defined by different prime numbers, their interferences produce an apparently **random behavior** for very long time before any possible repetition of the original **sequence**. Such repetition would be determined by the minimal product of the different **periods**. Thus the basic global **determinism** will remain hidden and very difficult to discover when a very long **observation period** is not yet available.

0

2324

OBJECT ^{1) - 2) - 3)}

1) A physical and observable entity endowed (by the **observer**!) with specifiable **morphological** and **functional** properties.

2) "A **set** of forces, with finite values, coordinated by a **regulation** system, in such a way as to produce stable and **observable** qualities, when left to itself in its natural surroundings" (C.P. BRUTER, 1973, p.33).

According to J.J. GIBSON we distinguish between objects as they lend us, or not some specific capabilities of **action (affordances)** (1986, p.133).

H.von FOERSTER sustains that "objects are representations of **relations**", an opinion that he even extends to "**events**" (1982, p.265).

Thus, the notion of object hovers at the confines of reality and **subjectivity** (individual or collective).

According to the given definitions, the object is not very different from the system (in its most general sense).

J.L.LE MOIGNE resumes as follows some of C.P. BRUTER's comments: "Within the **fields** of forces that occupy the **environment** (surroundings), the instantaneous **equilibrium** of these forces which create the observable object re-

sults from and is maintained by the object itself, which escapes somehow from its "parents" and develops its own identifiable project of existence" (1990a, p.151).

This concept is very close to LAVILLE's (1950), who however expresses it in a less tautological manner. LAVILLE shows moreover how "antagonistic **fields** of forces" give rise to the **forms** of the "objects".

This is also perceived by G. KLIR who states: "... the object, which is the subject of our interest, is never completely isolated from its **environment**" (1965, p.31).

J.von UEXKÜLL gave this lapidary definition, which confirms however that any object is an **observed** one: "An object is what moves together" (Quoted by K. LORENZ, 1962, p.47). We should maybe correct this statement as follows: "An object is what we perceive as moving together". In A.L. GOUDSMIT words it is the result of: "multiple **recursive** coordinated **actions**. We will, thus, regard objects as **elements** of **consensual domains** in that they consist of intricately stabilized **patterns of interrelations**" (1989, p.175).

G.P. SHCHEDROVITZKY distinguishes however between the "object and the "thing known", in these terms: "The object exists independently of **knowledge**. The thing known, on the contrary, is formulated by **knowledge** itself" (1966, p.32). There is a danger of semantic confusion: We should better consider the "object" as the result of our **observation** of "that thing there outside" (As proposed by A. KORZYBSKI - 1933 - 1950).

In the art photographer W. BULLOCK words (quoted by E. JANTSCH, 1975, p.90): "An object is actually a visual or mental **concept**. It has no independent physical existence. Only **events** exist". This view is very close to KORZYBSKI's ones.

H.von FOERSTER made the same point in his paper "Objects: **Tokens** for Eigen behaviors" (1976)

→ "**Organization, (the nine levels of)** (of **objects or systems**).

2325

OBJECTIFICATION ¹⁾²⁾³⁾

J.van GIGCH writes: "In EINSTEIN's science, "objectification" consists of inventing mathematical equations whose "**objects**" are mathematical **entities**. The senses and **perception** do not intervene in any way, except to the extent that observational **data** become "objects" of theoretical statements" (2002, p. 202)

van Gigch comments: "The extend to which these objects are conceived independently of perception or of empirical data is somewhat debatable" (ibid)

According to von FOERSTER such independence is a delusion. Einstein himself "conceives a threefold distinction between:

a) the external world

b) the **observer's** perception of that external world; and

c) our notions of it" (ibid)

Accordingly, EINSTEIN wrote: "As far as the laws of **mathematics** refer to **reality**, they are not certain, and as far as they are certain, they do not refer to reality"

The test is not about certainty or **truth**, but about practical usefulness.

→ **Mathematical truth; Objectivity; Ontological skepticism; Reality (Riddle of); Reference frame**

2326

OBJECT-IN- TIME ¹⁾²⁾³⁾

From the **phenomenological** viewpoint as presented by HUSSERL we perceive what we call "objects" only due to their relative **permanence** in time (Zeitgegenstand)

This can be compared with the way gravitational **fields** allow us to perceive space by structuring it.

More generally, we cannot definitely separate **matter** (objects"), **space**, **time** and **energy**. Anyone of these four phenomenological **percepts** is absolutely needed to make sense of the others. Their **whole** is our inevitable basic **frame of reference**.

From another- but related- viewpoint, our **brain** reflects this multi-complementary. As to the perceived time **flow**, the **hippocampus** is the seat of the **short-time memory** and the instrument of the development of the long-one. Without its **action**, we could not remember anything in a mental way. We would not benefit of what HUSSERL calls "retention".

→ **Correlation; Exclusion Principle; Interoception; Observation; Perception**

2327

OBJECTIVE ^{1) - 3)}

"... a preferred outcome ... which can be obtained over a longer **period of time**" (Adapted from R.L. ACKOFF - 1972).

As stated by ACKOFF, objectives are proper to **purposeful systems**.

He also understands that an objective encompasses a succession of intermediate **goals**: "Pursuit of an objective requires an ability to change **goals** once a **goal** has been obtained. This is why such pursuit is possible only for a **purposeful system**" (ibid).

For K. KRIPPENDORFF an objective is "the **goal, purpose** or **criterion** a **decision maker** uses to evaluated alternative courses of **actions**. The **choice** of objectives **constrains** possible **behaviors**" (1986, p.54).

In relation to his **metasystem** concept, J.van GIGCH writes: "The objectives of high-level systems will be labeled "high level" objectives; those of low-level systems "low-level" objectives. High-level objectives are not necessarily better than lower-level systems objectives...

"In a **hierarchy** of systems, it would be unusual to find that systems objectives or objectives in a **hierarchy** of objectives are independent of each other. Unless the **independence** of systems objectives can be assumed, their **values** cannot be incorporated in an **additive function**" (1978, p.376).

2328

OBJECTIVES (Multiple)^{1) - 4)}

S.S. SANGUPTA and R.L. ACKOFF consider that: "Perhaps the most important problem in the normative analysis of **man-machine systems** is the one presented by the multiplicity of objectives" (1965, p.44).

As noted by these authors, this is at least a two-sided problem: It depends on **optimization criteria** at the **management level**, but also, in not very decentralized systems, of **sub-systems** decision makers and even, in some cases, on individual participants objectives.

However, according to SANGUPTA and ACKOFF: "... it is not the existence of multiple objectives but the uncoordinated pursuit of these that typically causes **conflicts** within an **organization**". And: "The **complexity** that arises out of the pursuit of multiple objectives is due to the fact that there are **interactions** among the **goals** that are defined either for the system or its **subfunctions**" (Ibid.).

As stated by T.R. BURNS and L.D. MEEKER: "... multiple objectives cannot be satisfied simultaneously... No one course of action or outcome will maximize the achievement of – or possibly even manage to accomplish – all the objectives" (1976, p.114).

All this suggests that policies should be based on a sound **perception** by all the members of the **organization** of the objectives, not only those of the managers, but also those of the other members of the **organization**. Moreover, a good **understanding** of the global **organization** as a system and in systemic terms is a must, as well as at least a minimal **consensus**.

J.G. MILLER **taxonomy of subsystems and translevel hypothesis** could be very useful to such a discovery.

→ **Heterarchy and Holography as a metaphor**

2329

OBJECTIVITY^{3) - 4)}

The supposed capability of the human reason to observe and register reality as it is in itself.

In fact, this is a belief. For H. MARGENAU (as quoted by van GIGCH, 2002, p. 202), to EINSTEIN himself objectivity meant "the **belief** in an external world, independent of the perceiving **subject**, (which) is the basis of all natural science".

As we are all "perceiving subjects" and as such unable to escape this condition, we must unavoidably accept it as a postulated foundation for all **knowledge**. It is however clear that the postulate serves us quite well to understand and manage our surrounding **environment**...at least as long as we do not delude ourselves.

Objectivity was the bedrock of classical 19th. Century science: "The characters of the **observer** should never intrude in his/her **observations**", which imposes the absolute separation of the **observer** and the observed.

D. Mc NEIL writes: "Despite the persistent myth of perfect objectivity left over from the idealization of **mechanism** during the nineteenth Century, it has long been understood that, whether it be in quantum **uncertainty** or in social **interaction**, every **observation** is an intervention... more or less. Furthermore, it is absurd to claim that scientific endeavor is detached as long as it strives for "**prediction and control**" (1993b, p.4).

From a different viewpoint, H.von FOERSTER states that "objectivity" "... is the cognitive version of the physiological **blindspot**: we do not see what we do not see. Objectivity is a **subject's** delusion that observing can be done without him" (i.e. as an **observer**) (American Society for Cybernetics Declaration 1983).

The French economist J. FOURASTIÉ called this "ignorance of ignorance" and the Dutch systemist G.de ZEEUW developed a similar **concept** under the name of "**invisibility**".

The possibility of objectivity is indeed a **belief**, that leads to an **ontological** postulate. P. DELATTRE, (also quoted by J.L.LE MOIGNE) observes: "The very notion of objectivity is not so limpid as it seems to be. The **concept** of objectivity is closely linked with the one of more or less universal **consensus**, but this is certainly not sufficient" (1971, p.8).

This can be more or less easily done in the "objective world of classical science... subsumed as a special case of weak **interaction**" (i.e. between the **observing** and the **observed** systems) (R. GLANVILLE, 1979, p.37)

In other words, that which we call reality seems merely to mirror our most generally shared views about the equivalence of our respective **perceptions** and the interpretations that we elaborate on them: "objectivity" at its best is merely more or less enlightened and well founded agreement between shared **subjectivities**. As such, it can exist merely as "... a **systemic** property of the system of science taken collectively. Objectivity, if it results, occurs from a **process** of weeding out our conflicting claims" (I.I. MITROFF and H.A. LINSTONE, 1993, p.89).

Practical consequences in any human **activity** – scientific or other – are portentous: Presence of objectivity from the part of any **stakeholder** in any **issue** is merely either ignored **subjectivity** or, worse, a attempt to silence anyone proposing different views.

Also C.W. CHURCHMAN came to the conclusion that, as **subjectivity** can never be excluded, it should be included in any definition of objectivity (1971, p.169-72).

We are led in this way to **ontological skepticism**, which does not deny the existence of objective reality, but considers that is only possible to know it in a relative way, through more or less shared **models**, ever susceptible of further revisions.

This is of course the lesson of the whole history of science and, still more generally of human reason.

2330

OBJECTS OF REFERENCE¹⁾⁵⁾

"Virtual objects **representation** (that) becomes the **references** to anchor the **path** of intentional movement and to bind the visual **constancy** in object **perception**"(C.A. STECKNER, 1999, p. 101)

Objects of reference are obtained through a "**mapping process** (that) cuts the **action-relevant** external object qualities from the **environmental background** to constitute the needed true objects of reference within the **organization** of the personal **space**"(Ibid.)

A good example is the way the driver observes a red traffic light, awaiting its switching to green to proceed on his way.

The rest of the scenery recedes from his intended perception, but his attention focused on the traffic light is simultaneously **anticipatory** and **intentional**. It is a step in the construction of a complex **sequential behavior**

→ **Intentionality**

2331

OBLIVION EFFECTS¹⁾⁵⁾

There is a progressive erosion of **memory** in systems.

Two aspects seem most important:

- 1- No system has an unlimited capacity for memorization. It will tend to remember only that which has been repeatedly useful for practical **purposes** in its **behavior** (**HEBB's rule**) However, **long-term memory** may retain for very long time some unused **information**
- 2- In complex systems the **sensibility** to remembered **initial conditions** may lead to **chaotic behavior**. Losing memory of these **initial conditions** may deeply alter the behavior of the system

2332

OBSERVABILITY (Constraints on)³⁾

M. NOWAKOWSKA states (1986, p.52-4) as follows the observability problem: "The **phenomenon** to be observed is assumed to be described in terms of n **attributes**, say $y_1...y_n$. To determine the **state** of the **phenomenon** at any given **time**, one needs to know the **values** of all **components**."

"The constraints on observability may be of three types. Firstly, it is quite common that **values** of a given **variable** can be known only up to some precision" (p.52).

Practically this is *always* the case. For this reason, as noted by this author, it is generally necessary to use statistics. But in this case, it is implicitly admitted that a mean between **observations** of many similar **states** of many similar **phenomena** can validly be used.

"Another kind of restriction on observability is of conditional character: it is typified by a constraint that, if y_i assumes a **value** in some **range**, then one cannot observe the **value** of variable y_j ... In practice such situation occurs when some **values** (usually the extreme ones) cannot be observed at all, or prevent **observations** of some other **variable** or **variables**" (p.53).

"Finally, the third type of constraint concerns joint observability; it is typified by the situation where y_i and y_j may each be observed, but not jointly" (p.53).

This is basically the **indeterminacy** (or **uncertainty**) problem, very basic at quanta level.

"Of course, all three kinds of constraints may operate at the same **time** in a given **phenomenon**" (Ibid).

The use of the concept of "**state** of the **phenomenon**" clearly shows the fundamental **ambiguity** of any **observation**, that is always trying to "solidify" a dynamic succession of **events** into a sequence of static **states** (sorry for the pleonasm!).

In synthesis, even leaving aside physiological limitations, we are always trapped within our mental **dichotomy** between **time** and **space**.

2333

OBSERVATION (Conditions of)^{2) - 3)}

At our **macro-level** the observing act does not affect *sensibly* the observed (so-called) **object**. In any case, the **perturbation** produced by the observing act is normally infinitesimal and even generally escapes any possible **measurement**. However, this is true only for physical observations at **macro-level**, but not for **micro-level** ones.

In a different sense any mental component in an observing act modifies the **perception** of the so-called **object**. The **observer** and the observed thing or **event** can never be completely and clearly dissociated (S LUPASCO, 1972, p.104).

As stated by H.von FOERSTER, we thus need "an observational **epistemology**" (1992, p.44).

At least the following aspects should be taken care of:

- intentionality of the **observer**
- physiological limitations of the **observer**
- psychological and cultural bents (**mind-scapes**) of the **observer** (conceptual **organizational closure**)
- selected **level** of observation (grossly: **micro-, macro- or mega-**)
- characteristics of the observational device used. (these show us what their construction allows for and we translate according to our **knowledge** of their characteristics)
- **paradigmatic** orientation of the **observer** (for ex.: mythical, mechanistic, **reductionist** or **holistic** bent)

K. POPPER recognized the same situation: "The belief that we can start with pure observation alone, without anything in the nature of theory, is absurd... Observation is always selective. It needs a chosen **object**, a definite task, a point of view, a **problem**. And its **description** presupposes a descriptive **language**..." (1981, as quoted by M. DODDS and G. JAROS, 1994).

2334

OBSERVATION PROCESS: A Constructivist Interpretation³⁾

F. HEYLIGHEN explains: "In a realist interpretation, a **state** is an intrinsic property of a system, which is independent of the **observer**"... This may indeed be correct per se, but it is of no practical use, since "...In a **constructivist** interpretation, a **state** is a **construct** resulting from an **interaction** between the system and the **observer**, which is such that it allows the observer to find a maximum of **coherence** between the different results of observations (i.e. **subject-object interactions**). In general, no construction (**representation**) is optimal, and the advantages and disadvantages of a particular **representation** may be counterbalanced by different advantages and disadvantages of another **representation**." (1990b, p.498).

2335

OBSERVATION (Self)¹⁾³⁾⁴⁾

In the tracks of SOCRATES, E. MORIN states that we need a rationality that be not only critical, but also self-critical.

He writes: "**Learning** of self-observation is part of learning lucidity" 1999 (p. 55). If we cannot do it, we are condemned to self-deception in the guise of very "imperfect **perceptions** and hallucinating rationalizations"(ibid.)

Of course, the basic condition for self-observation is the acquisition of **awareness** under the guidance of systemic understanding of our own **complexity** (biological, mental and psychological) and of our interrelation with our natural and **socio-cultural** environment.

Self-observation by the **observer** is certainly a most needed endeavor...and at the same time probably the most difficult; as so many people are loath to question themselves.

It is however a systemic and cybernetic absolute necessity. We need a permanent **revaluation** of our views and **frames of reference**. And this amounts to a mental and even more difficult psychological disjunction from ourselves.

We would need **feedbacks** on our own thoughts and **decisions**, in order to try to avoid being puppets of ourselves (and, by the way, of other people)

This should start by self-inquiry, answering questions as for instance:

- why do I (drink, smoke, quarrel, etc.)?
- why did the results of this or that **decision** be so adverse?
- in which way did I misunderstood this **issue**?
- why is this fellow so hostile to me?

We should always remember J. FOURASTIE's comment: "There is something worse than ignorance; it is the ignorance of ignorance". And still worse is the ignorance of the causes of ignorance.

What we need basically are mental, behavioral and even physiological feedbacks to ourselves. If we don't know how to create and understand them, we cannot become good systemists, nor managers of ourselves or anything else.

→ **Autopoiesis; Behavior (Self-organizing); Cybernetics (2nd Order); Double-bind; Psychology (Systemic); Self-exception fallacy; Self-reference**

2336

OBSERVATION: The autopoietic view²⁾³⁾

O. THYSSEN (1995, p. 20) explains as follows the nature of **observation**, as understood by N. LUHMANN, in his **autopoietic** interpretation: "LUHMANN does not base his systems theory on **ontology**, but on **distinction**. Even being, or what is observed as real, is a distinction between being and not being.

"In **observing**, **autopoietic** systems use **codes** to distinguish between positive and negative values of a distinction, artificially doubling the world (+/-, true/false, government/opposition, good/bad)... They use **programmes** in order to distribute the +/- **values** of the **code** to positive and negative prototypes. And they use **interpretations** in order to link the prototypes to real world **events**"

Moreover:

"Any **observation** is based on the fundamental **distinction** between **self reference** and external **reference**. The two types of reference imply each other so that no **materialism** (only external reference) and no **idealism** (only self-reference) is possible. At the same time, the system **environment distinction** is an *internal* distinction, as no system can operate outside

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

itself. So, the world is at the same time "out there", as external reference, and "in here", as the re-entry of the distinction system/environment in the system.

"The "world" is a borderline concept which cannot be negated"

→ **Model; Models; Recursion; Recursivity**

2337

OBSERVATION WINDOW²⁾

T.H. F. ALLEN and T.B. STARR explain: "... an observation window is determined for a given observation principally by the extent in **time** and/or **space** of **integration** used by the **observer** as he observes" (1982, p.274).

2338

OBSERVATIONAL LANGUAGE^{3) - 4)}

The descriptive and interpretive language a culture uses during some period of its **evolution** to connect itself with **reality**.

This concept has been established and discussed by G.de ZEEUW, who describes it as a **set** of **rules** which state **constraints** in the way the **observations** are done, registered, ordered in some coherent mental **frame of reference** and communicated among members of the culture (1992).

Of course "... the observational language limits itself...by imposing **models** on the actors in an **interaction**, that is, imposing **criteria** for **interaction**" (Ibid.,p.1077).

As a result, no observational language gives an unrestricted access to **reality** and always leads to the impossibility to observe certain **situations**. As no language is perfectly transparent, there always some measure of "**invisibility**" (de ZEEUW's terminology).

de ZEEUW states that the observational language evolves through time, generally under the pressure of new necessities. He argues that we find ourselves in such a period of **transformation** of the observational language, in relation to the emergence of numerous new features in science and cultures.

The same point what made in a quite different way by the French philosopher M. FOUCAULT (1966).

The slow shift of observational languages, of which we are generally unaware, is probably universal and permanent.

2339

OBSERVER¹⁾

Any percipient **organism** able to acquire a degree of awareness and obtain some **understanding** of its **environment** and **invironment**.

The first who emphasized the peculiar situation of the observer was R.J. BOSCOVICH in his "De Spatio et Tempore" (1758). In R. FISCHER's words: "BOSCOVICH claimed that the observer can never observe the world as it is – only the **interface** (or difference) between him and the

world... the observer does not see the world as it is: only a "transform", that depends of his own **state** of internal motions, will be accessible to him in principle" (1991, p.96). Basing himself on experiences on sensory attenuation, FISCHER ends up with a "principle of neurobiological relativity", according to which "**changes** in **states** of **consciousness**... reflect perceptual-conceptual **adjustments**, i.e. relativistic **transformations** to the changing ratio of internal vs. external excitation" (p.99).

An observer always selects some **elements** from the **set** of all possible (for him/her) **observations**. He/she is thus what J. WHEELER (quoted by F. DAVID PEAT, 1988, p.37) calls a "participator". Why and how this **selection** is made, is a very basic foundation for the ulterior use, **reliability** and **validity** of the obtained conclusions. The weight of the "participator" in the **observation process** depends, under other aspects, on his/her relative **size** in relation to the observed **phenomenon**: this explains, for instance, why celestial mechanics looks so "**objective**". But there are also physio- and psychological distortions. These became a serious concern for all thoughtful systemists and cybernetists.

In synthesis: "... in making an **observation**, the observer is operating as a cybernetic **control** and **communication** system for the observed system" (R. GLANVILLE, 1979, p. 37).

In turn, the observed system reacts to the observation act. Thus the observed system "can no longer be thought as an independent and isolated system in the classical scientific sense" (Ibid).

The permanent use of some controls may provoke a progressive **resistance** of the controlled factor. This has been observed in the numerous cases in which a parasite or pathogen evolved new strains, resistant to ever-growing doses of the control drug.

A way out of this problem could be the application of the control factor in an irregular way in **time**, thus avoiding the constant exposure that leads to pest resistance. Another way is to apply the control factor only when a **threshold** of infestation is crossed.

This **model** could be useful every time a **control** is proposed in a naturally fluctuating **situation**.

H.von FOERSTER, and H. MATURANA and F. VARELA developed a systemic-cybernetic concept of the percipient conditions of any observer. According to this viewpoint, an observer perceives *basically anything* in **function** of her/his own internal **organization**, physical and/or cerebral-mental.

According to von FOERSTER: "Qualities that we believe finding in **objects** lie within the observer". As an example, he uses: "Obscenity: I show a picture to somebody and ask him if it is obscene. He says "Yes". As a result, I now know something about him, but not about the

picture" (1992, p. 85). We must however start by believing that the picture does exist! In any case, as noted by J.J. GIBSON: "The observer and his **environment** are complementary. So are the **set** of observers and their common **environment**" and "The **environment** persists in some respects and changes in other respects. The most radical **change** is going out of existence or coming into existence" (1986, p.15).

Moreover, we need to find out how these Foersterian "qualities" came in existence within the observer and even how the observer himself came into existence. The **autopoiesis** and **organizational closure** concepts give merely some inklings into these topics.

Another theory of the observer has been developed by G. JUMARIE (1980). Its basic features are:

- Any system can be defined only in relation to a given observer. Thus the **same object** would be perceived differently by different observers;
- An observer receiving **information** from his/her **environment** uses it to modify his/her internal **structure**. JUMARIE comments: "This axiom merely systemize the fact that all systems are more or less **adaptive**".
- To a higher degree of **knowledge** that an observer has of his/her **environment** corresponds a higher capacity to extract **information** from it.
- Any **universe** is blind to itself, i.e. unable to observe its own **transformations**. According to JUMARIE, this proposition is equivalent to **GÖDEL's theorem** relative to the **incompleteness** of the formal systems.

All this, when duly pondered, is more or less subtly related to the **organizational closure** concept.

2340

OBSERVER (Collective)¹⁾³⁾⁴⁾

According to K. BAUSCH, "the concept of **observer** may be considered at three **levels**

- 1- as generator of **relativity**, of **subjectivity**
- 2- as architect of **models** of other systems
- 3- as multi-systems having **components simultaneously** belonging to more than a single system, making different systems emergent even contemporaneously, such as occurs in flocks, **swarms** and social systems" (Glossary-Pers. comm., 2002)

So called collective observers are in most cases also collective actors, **agents** or **operators**. In fact, the model could be applied to all collective **behaviors**.

However such behaviors are frequently quite unstable (or even fickle): flocks, **swarms** or **crowds** are easily broken up...and reordered in a different way

In the case of crowds they are notoriously inconstant, unpredictable or apt to be manipulated (a good example is Marc Antonio's discourse to the roman crowd after the murder of Julius Cesar, in SHAKESPEARE's drama)

In fact there is always a shifting and unstable behavioral relation between any individual and the crowd he/she happens to mix up at any time.

Membership itself is frequently dubious and provisional. A reconsideration of the proposed concept in the light of **autopoiesis**, **conversation** model and **structure coupling** seems to be necessary

2341

OBSOLESCENCE ^{1) - 4)}

The characteristic of an **artifact** or technique which cannot anymore compete with more efficient newer ones.

Obsolescence started being merely a result of moderate technical **evolution**, as for example, for stage coaches being slowly replaced by motorized vehicles, or transoceanic liners by airplanes.

However, it is now a much more intricate systemic problem. First, capitalist economic dynamics introduced covert "planned obsolescence" as a way to foster early renewal of durable **artifacts**.

Now, the acceleration of technical progress is generating "non-planned obsolescence", as still very usable and not yet duly written-off **artifacts** are turned non-cost effective by new appliances.

The classical **model** of **life-cycle** is consequently no longer valid. As a result obsolescence must now be considered a **time-binded** systemic **situation** that introduces new types of **constraints** (and **stresses**) in economy and in society, which should become a subject of research.

2342

OCCUPANCY RULE ⁴⁾⁵⁾

The number of species able to maintain themselves in a specific area grows logarithmically in proportion to the area. (E.O. WILSON, 2000, p.15)

While this is originally an ecological one, it can be considered as a very general systemic occupancy **rule** since it corresponds to the growing number of permutations of the possible relations between a growing number of **elements** of some specific related kinds, as related to the diversifying **carrying capacity** of the area.

It is obviously valid for human establishments at different **levels**, from a small village to a great metropolis, and even the planet as a **whole**.

→ **Space Syntax**

2343

Ockhams' RAZOR ¹⁾²⁾³⁾

The exigency to explain any result - experimental or conceptual - using the smallest possible number of **concepts**. (Adapted from P. CHECKLAND, 1976, p. 28)

This method and philosophical principle is attributed to William of OCKHAM, the 14th Century's english monk philosopher.

The principle can be applied to "**top down**" **explanations** as well as to "**bottom up**" ones. This means that it should not be invoked to justify exclusively **reductionist** or systemic-holistic viewpoints. These in fact reflect an **asymmetrical complementarity**.

While very different, Ockham's Razor could be compared with G. CHAITIN's "**algorithmic complexity**", both are inquiries into the nature of simplicity in explanation.

Anyhow, some aspects of Ockhams's Razor should be scrutinized in a closer way:

- The most simple is not generally the most immediate ... and the most immediate is frequently not the most simple

- In the words of A. RAPOPORT: "Seek simplicity, but distrust it"

The most simple **explanation** may in some cases hide some unsuspected aspects, in need of some more complex **modelling** or **description**.... which could be the most simple, but at a wider or deeper **level of understanding**.

We may also seek and understand **simplicity** either at the typically **reductionist** or, on the contrary, at the **wholeness level**.

2344

OLIGOPOLY STATES (Law of) ^{1) - 2) - 4)}

"If there are competing **organizations**, the **instability** of their relations and hence the danger of frictions and **conflicts** increase with the decrease of the number of those **organizations**." (L.von BERTALANFFY, 1956, p.8).

This law, which was first stated by V. VOLTERRA (1931), is applicable for example to competitive **populations**: thus ecological systems with numerous complementary species are more stable than those which count with only some few (This is why monocultivation brings along so many problems). VOLTERRA showed that in systems scantily diversified, destruction of the prey species by the predatory can lead to the disappearance of the latter altogether, due to the lack of any alternate **resources**.

The application of the law to economical oligopolies is not so obvious, but would be an interesting subject for scrutiny. Moreover, while **conflicts** between a reduced number of very big **organizations** can be very costly, it should be interesting to consider other aspects as for example the total costs of numerous small local

conflicts between **organizations** of a lesser **size**, or what could be the significance of a prey-predator analogue relation between differentiated **organizations**.

2345

OLYMPIAN STANCE ³⁾

The position of a researcher that imagines him/herself in an absolutely separate and objective position in relation to the **object** of his/her research.

This attitude is also known as self-excepting fallacy. Such stance ignores the various perceptive **limits** that obstruct our full **knowledge** of reality. It also ignores our internal perceptive and cognitive **organizational closure** that conditions our concepts formation, mental **frames of reference**, **models**, viewpoints, psychological biases, etc...

The Olympian stance leads easily to mind blocks, illusory **objectivity** and even intolerance for others' opinions.

This expression was introduced by the anthropologist G. DEVEREUX

→ **Blindspots**

2346

ONTOGENESIS ^{2) - 5)}

The **process** of **self-organization** of a biological system, starting from an initial **structure**.

E. JANTSCH defines the very similar term of "ontogeny" as "the **evolution of self-organizing space-time structures** in a coherent way through **changes** in the dynamic **regime**" and adds that "It arises from **dissipative self-organization** which, in principle, defeats any structural permanency (NICOLIS and PRIGOGINE, 1977) and may be interpreted as **dynamical self-reference** - not with respect to a single **structure**, but with respect to an evolutionary **path of structures**. The system is **self-referential** in terms of its own **evolution**" (1982, p.344).

It would be interesting to translate the concept into the study of animal and human societies: How do they organize themselves in coherent **complex systems**?

2347

ONTOGENY ¹⁾⁵⁾

"The **process** of **development** of the individual: embryology plus whatever changes in **environment** and **habitat** may impose" (G. BATESON, 1979, p.229)

The interesting point thus made clear is the importance of the direct and indirect (habitat) impacts on the original **structure**.

But does the ontogenic **process**, as thus understood, finally ends at some precise **time** in the system's life?

¹⁾general information²⁾methodology or model³⁾epistemology, ontology and semantics⁴⁾human sciences⁵⁾discipline oriented

2348

ONTOLOGICAL SKEPTICISM or AGNOSTICISM³⁾

Classical science is founded on the firm belief in our possibility to observe nature in an objective way, which is not the same as the postulate about the objective existence of nature.

The difference lies in the classical standpoint that ascribes an absolute **objective value** to the observed "**facts**" without being aware that these "**facts**" are *constructed* through perceptive and conceptual **filters**, in accordance with human physiological and cerebral *characteristics*.

This point – already made by BOSCOVICH in 1758, in his "De spatio et tempore"!, as quoted by R. FISCHER (1991, p.96) – is neatly stated by E.von GLASERSFELD: "The fact that we can coordinate our own sense **data** (very low-level mental **structures**) into recurrent **structures** (low-level mental **structures**) can never prove that these **structures** are ontologically real – it only proves that the individual **data** occur frequently enough in our experience for us to establish *invariant* co-occurrences" (1988, p.13).

von GLASERSFELD himself quotes this significant paragraph in L. WITTGENSTEIN's "Tractatus logico-philosophicus": "In order to discover whether the picture is true or false we must compare it with reality (...). How could one possibly carry out that comparison?"

And he concludes in a rather radical way: "Ontological **reality** is a matter of belief" (1991, p.115)

According to M.C.LE DUC "mental **structures**" should be understood as concrete **structures** in the nervous system" (1992, p.918). We cannot know anything if not in a physiological way.

This also justifies A. EDDINGTON observation that we only can see what our **epistemology** allows for, i.e. on the base of the value we recognize to our own **perceptions**.

It seems anyhow natural and even unavoidable to *postulate* the objective existence of nature (i.e. our **environment**). E. SCHWARZ writes: "... human **knowledge** is a gradual human construction, shaped in **interaction** with the **environment**; it is thus a co-construction which reflects the **attributes** of the knowing **subject** as well as these of the **object of knowledge**" (1994, p. 582). It is thus certainly foolhardy to attribute an absolute **value** to that which we believe we know about our surroundings.

Similarly, St. KATZ observes that: "Though the **subject** may attach ontological significance to the items it knows, those who see the **subject-environment relation** within the framework of **neural computation** believe differently" (1976, p.44).

Ontology of **knowledge** is definitely a slippery subject. The systemist seems thus doomed to a prudent ontological agnosticism or skepticism, but should avoid nihilism altogether (FEYERABEND's for example).

2349

ONTOLOGY (Constitutive) (H. MATURANA's)³⁾

R. HARNDEN explains constitutive ontology in this way: "Instead of making claims to go beyond or transcend **understanding** by pointing toward eternal, immutable verities, a constitutive ontology rest its claims for reality with whatsoever is brought forth by the individual **observer**, in the course of the **consensual** coordinations of **actions** in a **community of observers**" (1990, p.294).

"When used as a synonym for "**objectivity**", ontology is ascribed a transcendental status. It suggest something over beyond what is known, something that might be referred to as Reality or as **Truth**. This Platonic legacy is what is denied by MATURANA's insight into a constitutive ontology. When we place **objectivity** in brackets, we are left with a world or better, a series of individual **cognitive spaces**, in dynamic relations with one another and the global **environment**." (Ibid, p.294).

and finally...

"No statement for or against **Objectivity** is being made." (Ibid.).

When one objectivizes in an absolute way, what he/she really does is create a theater of ghosts, with a dangerous potential for self-deception, illusory **idealization** and, easily, ideological intolerance.

2350

OPENNESS²⁾

The more or less free **flow of matter and energy** from the **environment** into the system and vice-versa.

A. COLLEN et al (1994, p.65-68) make the following relevant points: "Most **concrete systems** have **boundaries** which are at least partially permeable, permitting sizable **magnitudes** of at least certain sorts of **matter-energy** or **information transmission** to cross them. Such a system is an **open system** (in which) **entropy** may increase, remaining in **steady state** or decrease. The classical notion of openness can be named the **thermodynamic** one..."

"A system can be opening or closing, which emphasizes the **processes** of the system.

"With respect to the **hierarchy** a system can be open or closed at different **levels**..."

The authors distinguish various types of openness: passive or active; tactic or strategic, and establish a table comparing closedness to openness, as follows:

"From closedness

Passive
Insensitive to its **context**
No learning
Object-oriented
Inflexible
No changing of **rules**
Avoiding contradiction

to openness

Active
Sensitive to its **context**
Learning
Process-oriented
Evolving
Changing of **rules**
Using contradiction to evolve
Generating multiple hypothesis
Inductive
Cannot be disassembled and reassembled
Inclusive of the **observer**, who is inside the system

2351

OPERAND²⁾

An **element** on which an **operation** is performed

The **element** can be material or abstract, simple or complex.

2352

OPERATION²⁾

"A basic **process** that applies to an **operand** and yields a transform" (K. KRIPPENDORFF, 1986, p.54).

KRIPPENDORFF gives as examples "the multiplication of two numbers, driving a nail with a hammer, baking" (Ibid).

R. ACKOFF gives the following descriptive definition of the term: "Loosely put, a **set** of acts can be said to constitute an operation if each act is necessary for the occurrence of a desired outcome and if these acts are interdependent. The nature of this **interdependence** can be precisely defined. The relevant outcome involved in an operation can each be defined by a **set** of properties which can be treated as **variables**" (1960, p.2).

ACKOFF wrote this in 1960. One wonders if this quite deterministic attitude, proper at the time of **operations research** could still be maintained nowadays in view of what we are learning from **chaos theory** (even in man-managed systems), particularly in systems with various and more or less independent **initial conditions**.

2353

OPERATION LAG¹⁾

The **time lag** "caused by the actual functioning of the **components**" (R. ROSEN, 1966, p.39).

R. ROSEN distinguishes operation lags from transport or other **lags**, which results of **delays** in the **transmission of effects** between **components** or **subsystems**.

He explains that: "If a **component** produces more than one **output**, then each of its **outputs** will have its own operation lag. Further, in the most general case, the **time** required for a **component** to produce an **input** depends on the particular **input** materials with which the **component** was supplied" (Ibid).

Like any **time lag**, the operation lags introduce **heterogeneity** in **space** and **time** into the system. This can be damaging or, on the contrary, useful for its **coherence**.

Different operation lags normally introduce a certain **indeterminism** into the system.

2354

OPERATION RESEARCH⁵⁾

L.von BERTALANFFY gives the following definition: "Scientific **control** of existing systems of men, machines, materials, money, etc..." (1962, p.3).

St. BEER, in "Decision and Control" is quite cautious and recoils from any limitative definition. He prefers to describe what O.R. does: "Operation research is the attack of modern science on complex problems arising in the direction and **management**...- of what exactly?" His reply is "Of enterprises" but he immediately ask himself: "What is really an enterprise, as seen from the scientist's viewpoint?" (1968, p.89).

BEER's subtle view is systemic-cybernetic in the most complete sense, since O.R. must construct **models** and that no **models** of **complex systems** as enterprises or **organizations** can be constructed (and put in perspective) without the help of multiple systemic and cybernetics concepts.

O.R. uses tools such as **linear programming**, **games** and **computer simulations**, developed through specific theories thus enumerated by R. ACKOFF: "...allocation, queuing, sequencing, routing, replacement, competitive, and search theories" (1974 b, p.57).

R. ACKOFF describes O.R. in the following terms: "The essential characteristics of this **interdisciplinary** activity lie in its **methodology**. Out of an analysis of the desired outcomes, **objectives** of the **organization**, it develops a measure of performance (P) of the system. It then seeks to **model** the **organization's behavior** in the form of an equation in which the measure of **performance** is equated to some **functions** of those aspects of the system which are subject to **management's control** (C_i) and which affect the desired outcome, and to those controlled aspects of the system (U_j) which also affect the outcome.

"Thus the **model** takes the form:

$$P = f(C_i, U_j)$$

"From the **model**, values of the **control variables** are found which maximize (or minimize) the measure of the systems performance:

$$C_i = g(U_j)$$

"The solution, therefore consists of a set of **rules**, one for each **control variable**, which establishes the value at which that **variable** should be set for any possible **set** of values of the uncontrolled **variables**" (1974, p.5).

Operations research has proved quite useful in numerous cases. However it knows of severe limitations, as stated by ACKOFF, himself a recognized leader in O.R.: "It will be recognized that this procedure is one by which equipment systems should be ideally designed... Unfortunately, in many cases such a **model** of a desired equipment system cannot be constructed because of our ignorance... Nor is there sufficient **knowledge** to relate any of the less perfect available measures of **performance** to the large number of **design variables**... As a consequence, **design** is currently accomplished by a combination of scientific analysis, intuition and aesthetic considerations".

Even so, in his 1960 paper, ACKOFF was optimistic: "It should be recognized however, that current **design** procedures are only an evolutionary stage which will be replaced as rapidly as possible by effective **modelling** and the extraction of solutions from the resulting **models**" (Ibid).

ACKOFF himself later contributed with his **interactive** or participative **planning** a new approach that tries to mend some of the O.R. problems.

However, more than 30 years later hopes for better solutions seem to have been at the same time furthered and dashed with the development of **chaos theory** and **thermodynamics of the irreversible systems faraway from equilibrium**: **Complex systems' behavior** can never be forecasted in a perfectly accurate way. However, the limits to **predictability** are now better understood.

On the other hand, one of the first O.R. enthusiasts, C.W. CHURCHMAN, recognized in 1979 (as quoted by M.C. JACKSON, 1992, p.255) "that the original intention of a **holistic, interdisciplinary** experimental science adressed to **problems in social systems** was betrayed as O.R. degenerated, in the 1960s, into little more than mathematical **modeling**".

Many practitioners would even be surprised to learn that it was ever intended to be more than that!

The practically insoluble difficulties encountered by FORRESTER's **world dynamics** were a early harbinger of this situation.

2355

OPERATIONAL RESEARCH (OR) reconsidered¹⁾²⁾

In a recent article, I. MUNRO reconsiders the history and the present state of organizational research (1999, p. 513-532)

As to the historical aspects, after retracing the origins of OR during World War 2, he argues that it quickly derived into a mechanized view of **reality**, even if most research teams included people from many disciplines.

The basic six-stage recommended **methodology** was as follows:

1. Formulate the problem
2. Construct a mathematical **model** to represent the system under study
3. Derive a **solution** from the model
4. Test the model and the solution derived from it
5. Establish **controls** over the solution
6. Put the solution to work"(p. 516)

Of course, such a **methodology** is highly formalistic and **mechanistic**, specially when the "problem" is considered without any reference to the many human aspects (developed -for ex.- in J. WARFIELD's Generic Design).

MUNRO states: "(the) models tend to be constructed entirely from things that have been quantified and measured"...which is fine when the "problem" is for ex. the build-up of a new production line for a new car model (in a non-technical and human **environment** whose **stability**- or even asepsy!- is taken for granted)

MUNRO proceeds with a study of the cultural settings which led to this kind of OR, including economic and social biases that become even clearly reflected in **language** (p. 518)

He then retraces the advent of more integrated views in so-called "soft OR" and refers himself to authors like CHURCHMAN, ACKOFF and CHECKLAND and goes so far as quoting Samuel BUTLER's "Erewhon": "May not man himself become a sort of parasite upon the **machines**. An affectionate machine-tickling aphid?"(p. 521)

Finally, it shows clearly that man-machines systems classical OR is much more about machines than about men. As a result we should remember ACKOFF's quip about "doing perfectly things that should never have been done in the first place"

MUNRO advocates in the last part of his paper for reworking of the basic idea of **man-machine system**: Men use machines and the ways machines are used- or could, or should be used - cannot be ignored in soft OR. He quotes MINGER'S approach according to which "...problem solving in the real world does not simply involve finding the right **code** of conduct or the right **methodology** to suit the circumstances, but requires that questions be asked about the experience of the **agents** involved, their past history and their various commitments" (p. 529) and the need to discuss "technologies of the **self**".

One wonders if such a new kind of OR does not totally escape the limits of the technical **aims** and tools of OR itself. Again, J. WARFIELD (and other authors like ACKOFF, MITROFF and LINSTONE and CHECKLAND himself) seems nearer to the point with his **Generic Design**.

2356

OPERATIONALISM

A philosophical doctrine holding that the **meaning** of a **concept** can be defined only by a set of actual experimental **operations**.

In its most radical interpretation, operationalism demands that such operations be measurable.

From a systemic view point, this seems to be too restrictive, as it prohibits not only **metaphors** or **analogies** but altogether seemingly qualitative **models** as for example **topological** ones.

It is also quite difficult to see how the traditional **frame of reference** of thought in general **-logic** for instance- can be redefined in operationalism terms.

But the unending-and many times doubtful, if not contradictory-meanderings of all kinds of philosophies undoubtedly explains and justify the need to find a stronger bedrock for thought.

Accordingly the basic tenet of operationalism is the need to find a way to eliminate all concepts that cannot be connected to some empirical **reality**. This exclusion apply mainly to those "ghostly" internal psychological concepts whose meaning is perpetually controversial because of their more or less imaginary, or limit-edly cultural, or imprecise character.

The main root of operationalism is in Ch.S. PEIRCE (1839-1914) original version of **pragmatism**. However, its principal proponent has been the american physicist P.W. BRIDGMAN (1882-1961)

H. MATURANA and F. VARELA's views about the ways of **cognition** and its autopoietic character ("**Santiago theory**") reset the whole of operationalism in a new light: Cognition may never become really measurable, but at least it is becoming more rationally- and "operationally"- understandable

2357

OPERATIONISM³⁾

A philosophical doctrine holding that the **mean-ing** of a concept can be defined only by a set of actual experimental **operations**.

In its most radical interpretation, operationism demands that such **operations** be measurable.

From a systemic viewpoint, this seems too restrictive, as it prohibits not only **metaphors** or **analogies** but altogether seemingly qualitative **models** as for example **topological** ones.

2358

OPERATOR²⁾

"A **transformation** or **transition rule** mapping initial **states** upon subsequent **states**" (F. HEYLIGHEN, 1990a, p.426).

The operator determines "... a **time-parametrized trajectory** in the **state space** representing the **states** of the system at subsequent instants" (Ibid).

The **concept** of operator is close to the one of **algorithm**. An operator is a specific part of an **algorithm**. Its total or partial activation at some moment depends on the **dynamics** of the **constraints**.

"An operator corresponds to a **distinction** between the **state** before the operator was applied and the **state** afterwards" (Ibid).

In a **recursive machine**, as for instance a **TURING machine**, the operator is the significant **element**, not the **input**, which is merely the **trigger**. The **input** must however be "legible" by the operator.

The previous comment suggest interesting parallelism with human "operators".

J.L.LE MOIGNE advocates for the development of a specific notation for different types of systemic operators, as for example:

- the **recursion** operator, proposed by E. MORIN
- the **distinction** operator (G. SPENCER BROWN)
- the **autonomy** operator (F. VARELA)
- the **combinators** (H.B. CURRY)

He also mention the conservation **symbols** used by J. FORRESTER in his **Systems Dynamics** (1990, p.115).

2359

OPERATOR (Decision)²⁾

A decision **process** operated by a system in correspondance with its **observation** of the **set** which includes its **environment** as well as itself.

R. VALLÉE, who introduced the concept, writes: "If we want to model the decisional **process** which follows the **observation process** (**processes** which are artificially separated for intellectual commodity but, in fact, are only one) we must go on from y , a **function** describing the **evolution** of **perceptions**, to **function** z describing the **evolution** of **decisions** or **controls** decided at each instant (in a way considered here as automatic for the sake of simplification) which must act upon the **effectors**: $z = D(y)$ where D is a **decision operator**" (1990, p.40).

Considering that y represents what the system perceives through the **observation operator** (a "distorted and impoverished image" of the real **situation** and its **evolution**) we have thus $z = D(O(x))$.

VALLÉE calls this product the **pragmatic operator**.

2360

OPERATOR (Difference)^{1) - 4)}

The use of observed **differences** to distinguish and construct **classes** and **categories**.

D. DUBOIS observed that the first ability used by the small baby is the capability to recognize a **difference** between two **objects** of its **environment**.

Later on the baby becomes able to make multiple discriminations and finally to register similarities between different **objects**. In this way it acquires the ability to sorting out multiple discriminations and start to establish in this way hierarchical **classifications**. (1991, p.5).

2361

OPERATOR (Observation)^{2) - 3)}

Observation process operated by a system on itself and on its **environment**.

The observation operator, traduced into a mathematical formalism created by R. VALLÉE (1951a, p.1350-1; and b, p.1428-9; 1987c, p.460-2; 1995, p.35-58 and 71-82) is used to define the observation **limits** characteristic of an observing system.

R. VALLÉE, who introduced the concept, states: "The **object** considered here is the very **evolution** of the system and its **environment** which cannot logically be separated, an **evolution** which is described by **function** $x : t > x(t)$ where t represents an instant. The distorted and impoverished image of x , which the system perceives, is **function** $y : t > y(t)$: being understood that, at instant $ty(t)$, *what the system believes is* $x(t)$, representing the pair constituted by the **state** at instant t , of the system and the **state**, at instant t , of its **environment**" (1990, p.39).

It emerges from this that what the system believes it knows is in fact an imperfect **model** of the objective **situation**. It is, in VALLÉE's terms a case of "**epistemological subjectivity**".

A system may have various observation operators, corresponding to different interrelated **subsystemic functions**. VALLÉE describes the rules of observational **interactions** between 2 or more observation operators (1995, p.37-8) by combining a memorization operator, a decisional operator and an acting (or effecting) operator. This **set** describes globally in mathematical terms all possible **interactions** between the system and its **environment**, leading to what VALLÉE calls the "**epistemo-praxeological loop**". Interestingly, he observes that he thus reformulates the basic epistemological **meaning** of PLATO's Cave.

→ **Transfer (Inverse)**

2362

OPERATOR (Pragmatic)²⁾

A **process** operated by a system on itself and on its **environment**.

R. VALLÉE, who introduced this concept, explains that the pragmatic operator is the product of the **observation operator** and the **decision operator**, i.e.: $P = D.O.$

The system is limited and directed in its **action** by the "distorted and impoverished" character of its **perceptions**, on which it must ground its **decisions**.

2363

OPERON⁵⁾

A biological formal unit of **control**.

This concept has been introduced by the French biologists F. JACOB and J. MONOD, to explain dynamic **coordination** in biological systems.

While related to the **neural net model**, significant differences are pointed out by R. ROSEN: "It must be stressed that the operon is a purely formal unit. It is not a physical particle, nor is it composed of such particles. It cannot be isolated physically from the cell to which it belongs. It is thus not like a neuron in a **neural net**" (1979, p.182).

This opinion may now seem unduly restrictive in the light of the discovery of "homeoboxes" (very similar in mammals as well as in insects), i.e. groups of genes on specific chromosomes, which act as coordinated and sequential organizers of the whole **living system** (W. GEHRING, 1995, p.58-64).

Operons correspond thus to the potential properties of this kind of global basic **templates**, which remained astoundingly stable during eons of **evolution**.

Operons and homeoboxes introduce the intriguing question of the possible existence of a still more general systemic organizing principle active through different ways in systems of all kinds.

(For more discussion of this difficult notion, see references)

→ **Autogenetic system precursor; Meme; Replication and Zero System**

2364

OPPOSITES (Union of)²⁾

The character of **interrelations** that are at the same time **antagonistic** and **synergetic**.

Such a view disregards the traditional mutually **exclusive** character of opposites, which merely reflects the very strongly **dichotomic** bias in Western philosophy.

H. SABELLI and L. CARLSON-SABELLI write: "Every **process** contains complementary opposites, herein including **energetic** polarities, two-valued **information** and **structural symmetries**. Rise and fall, positive and negative, woman and man, right and left, **cooperation** and struggle, union and separation, **similarity** and **difference**, **symmetry** and **asymmetry**, necessarily coexist. In Heraclitus' magnificent

words, there is harmony in strife and strife in harmony. In contrast, logic postulates the absolute separation of opposites, a premise that leads to black and white thinking" (1994).

H. SABELLI also states: "The term opposition refers to both **synergetic** and **antagonistic interactions**. This apparent **ambiguity** of **language** reflects the fundamental fact that **synergetic interactions** and **antagonistic** ones are closely associated" (1991, p.2).

2365

OPTIMALITY (Sub-)²⁾

Premature **stabilization** of a solution prescribed by a search **algorithm**.

Sub-optimality can be prevented by the use of a **genetic algorithm**, which allows **self-learning processes** in constructed **machines**, or so-called "natural" ones.

2366

OPTIMIZATION²⁾

The search for the best possible way to reach the best possible **state** of a system.

The global optimization of a complex system is a permanently renewed transaction between stable or changing **constraints** bearing upon different **functions**, all needed for the **survival** of the system. In S. KAUFFMAN words: "In such optimization searches, many **parts** and **processes** must become coordinated to achieve some measure of overall success, but conflicting "**design constraints**" limit the results achieved" (1993, p.33).

2367

OPTIMIZATION (Sub)^{2) - 4)}

"The attainment of some kind of **optimum** in part of the system (which) precludes the attainment of an **optimum** for the **whole**" (K. BOULDING, 1972, p.84).

K. BOULDING states that this problem "which emerges out of economics... has a highly general significance" (ibid).

It arises, in human **organizations**, out of the inadequate – and in some cases downright non-sensical – use of technical tools applied to inadequate ends.

From another angle, K. BOULDING adds: "Many of the failures of **organizations**, for instance, are a result of suboptimization, which could be defined as the best way of doing something which should not be done at all, or more generally, finding the best way of doing something in particular without taking account of the **costs** which this solution imposes on other segments of the system" (ibid).

Suboptimization is a very general and dangerous result of hyperspecialization, as most **specialists** merely see as their duty managing and resolving as best as possible their own small segment of a global **situation** they consider to be outside their commitment... if even they are conscious of its existence.

2368

OPTIMIZATION THEORY²⁾

"A mathematical technique for determining the most profitable or least disadvantageous **choice** out of a **set** of alternatives" (K. KRIPPENDORFF, 1986, p.55)

This author states: "Typically the **set** of alternatives is restricted by several **constraints** on the values of a number of **variables** and an **objective function** locates the optimum in the remaining **set**" (ibid).

This is a technique used in **Operations research** and **Systems Analysis**. It should be observed:

1) That the definition of the **constraints** is outside the scope of the technique, as they are either discovered or prescribed by the **decision maker** (soundly or not). **Constraints** discovery is a typical systemic topic.

2) That optimization of a **process** or a **function** is different from the global optimization of a system, as for example an enterprise, and that **trade offs** are inevitable between **optima** defined for various **functions** or **processes**. **Maximization** of one of these frequently means sub-optimization of another or various other ones.

3) The technique in itself is "blind" to these global aspects of optimization. It is a good servant, but a suspicious master.

2369

OPTIMIZER²⁾

A **controller** able to seek by appropriate search the best possible maximum.

Such a **controller** must be endowed with a sufficient **memory** capacity in order to store the progressive results of its search, and with an **iterative refinement algorithm**, if it is not to remain trapped in a **sub-optimal situation**. (G. PASK, 1961, p.65).

2370

OPTIMUM^{1) - 2)}

The best possible condition for a system.

This very simple definition occults quite difficult **problems**. An optimum is generally **defined** by some **decider** in relation to some partial view of the system, corresponding to the aims sought by some **subsystem**. Optima are even frequently confused with maxima in specific **outputs** of the system. Maxima in turn, frequently can be sustained only for quite a

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

short **time**, until some basic **resource** of the system becomes depleted. (This **resource** may even be the permanence of **sinks** able to absorb constantly the products of the system).

The basic optimal condition of a system should guarantee it an adequate **stability margin**. In other words, specific **controls** should be correctly interconnected and interacting in order to allow the system *as a whole* to maintain its **dynamic stability**.

For example, production and consumption can be maintained more or less close to an optimum if their necessary **interdependence** is recognized. And both can be maintained stable at **long term** only if their **interdependence** with environmental conditions is recognized and respected.

2371

OPTIMUM (Dynamic)¹⁾²⁾

In a **growth process**, the moment at which the growth coefficient reaches its maximum. (C. GINI, 1952, p. 18)

C. GINI, an Italian demographer, used the concept in the study of **populations growth**, specially as related to the logistic **growth model** introduced by P. VERHULST (1838)

Dynamic optimum is a fleeting moment, after which growth starts to loose momentum, due generally to **negative feedbacks** from the **environment** of the system. Such feedbacks are in fact a **response** of the environment to the pressure that the system exerts on it, as for example an excessive use of non-renewable (or even renewable) **resources**, or the environment saturation, as a receiver of the **outputs** of the system. This can be for instance market over-saturation due to excessive production, or poisoning of the environment by unassimilable **waste**.

The question as if a dynamic optimum could be improved, by which means, and at which costs, remains open.

→ **Growth (Logistic); Logistic equation**

2372

OPTIMUM (Local)²⁾

The best **value** for a **function** in an **adaptive system** at some specific **time**.

This is however not necessarily the best possible value in its whole **range**.

If no provision is made in the genetic adaptive plan of the system in order to avoid blockage at such a value, the best possible **adaptation value** may be missed

2373

OPTION^{2) - 4)}

"Any possible **action** that might assist in resolving an **issue**" (J. WARFIELD, pers. comm.)

J. WARFIELD introduces the concept in his **Interactive Management methodology**.

The first and most important stage in **design** is the generation of options. Systemics opens the way to a wider field of options, as it broadens the field of inquiry and tries to avoid **underconceptualization**.

After generation, the options must be selected according to defined **criteria** and categorized. This is done by the **group** in charge of the **design**.

→ ("Nominal Group Technique" and "Interpretive Structural Modeling")

In view of the more or less unpredictable **changes** that the system can undergo, options should be maintained open as long as possible without risk for the system itself.

2374

ORBIT²⁾

The representation in the **phases space** of a **continuous** or **discontinuous trajectory**.

Orbits may be asymptotic, **periodic**, quasi periodic, non periodic or transitory (E. LORENZ, 1995, p. 216)).

→ **Phases portrait; Phases transition**

2375

ORDER^{1) - 2)}

The set of possible **interrelations (synchronic and diachronic)** among **elements**, arranged in a collection or in a system.

According to E. LASZLO: "Order in a system refers to the **invariance** that underlies its **transformations of state**, and by means of which the system's **structure** can be identified" (1974, p.210).

However "these relations... can undergo **transformations**" (Ibid). An hydrogen atom in a water molecule can be again separated, and enter in other combinations. However, through fusion, it disappears, becoming partly an **element** of an helium atom, "minus a radiated surplus of **energy**" (Ibid). The concept of order also becomes more and more elusive at higher degrees of **complexity**.

The concept of order includes **structures, functions** and, or **processes**.

At least three different types of order may be distinguished:

1°- **Algorithmic order**

The complete **set** of possible **interrelations** is precisely **prescribed** in a **set** of **invariable** instructions. Generally the sequential order of succession of the various but exclusively possible **states** is also prescribed.

2°- **Statistical order**

The **set** of possible **interrelations** becomes slowly revealed by a sufficient number of **observations** or experiments.

The sequential order of the possible **states** is frequently indeterminated (**Markov chains, Chaos**).

If an **algorithm** can be extracted from the statistics, its predictive value remains always doubtful: Averages are never totally free of atypical **fluctuations**.

3°- **Innovative order**

This is the so-called order (or **complexity**) from **noise**. It is proper of **self-organizing** systems who enhance their **variety** by using part of their internal **redundancy** to give significance to **noise** coming from their **environment**.

The study of increase, conservation or destruction of order are considered among others by **synergetics, thermodynamics** and **autonomy** theory under its various guises.

2376

ORDER and ENTROPY^{1) - 2)}

K.D. BAILEY comments: "a high degree of order indicates a system which has a low degree of **entropy**, and high degrees of **energy, information** and **negentropy**. Conversely, a system showing a low degree of **integration** has high **entropy**, with low **information, energy** and **negentropy**. We have specifically excluded the terms "**complexity**" and "**organizational complexity**" as they have not been adequately defined in the literature" (1987, p.92).

However, highly **dynamic systems** produce more **entropy** than the others, thanks to the absorbed **energy**, that they **dissipate** to order themselves. But, while they conserve or increase the acquired order, they export more **entropy** towards the **environment**. This is why some authors say – creating some confusion – that **entropy** grows with order. It should be said that order may grow *locally* only if **entropy** grows *globally*, as the ordering system produces more **entropy** but exports it toward the **environment**.

See: **Maxwell's Demon Paradox**.

2377

ORDER and ENVIRONMENT^{1) - 2) - 4)}

Order can increase within a system only if it is able to convey an increased **flow** of **entropy** into its **environment**. This implies that the **environment** must be **colder** than the system. R. FIVAZ puts it as follows: "... the **second principle** is preserved because the **environment** receives the latent heat flowing from the ordering system; as the **environment** is colder, its disordering is numerically larger so that the total **entropy** is indeed increased (1991, p. 22).

This is the ultimate relational problem between high **energy** degrading human systems and the global warming of the planet as the global **ecosystem**.

2378

ORDER and RANDOMNESS^{1) - 2) - 3)}

The relation between order and **randomness** remains still a vexing problem.

While a **complex system** needs strong **constraints** to maintain its **coherence**, these **constraints** reduce its adaptive potential and do not allow it to be more than a **link** in the chain of **evolution**. On the other hand, absolute randomness would preclude any order at all. Our conceptual opposition between order and **randomness** seems to be one more of these more or less artificial mental **dichotomies**.

When numerous **elements** of one kind become connected as in a **population**, or even in a **composite system** at its **critical state**, order seems to spring out from **randomness** at the so-called **edge of chaos** (self-organized **criticality**), probably because some **rules of behavior** emerge and stabilize. The cause or condition seems to be, for the **population** or **composite system**, to receive recurrent **inputs of energy**.

2379

ORDER (Degrees of)^{2) - 3)}

According to D. BOHM and F.D. PEAT, order is **embedding**, or **enfolding**, or **implicite** (1987, p.121 - 129).

These authors hypothesize "orders of infinite degree... which contain a very rich but little explored domain". They contend that: "Within this domain are to be found whole ranges of subtle and complex orders, some of infinite degree, which contain **embedded** within them many orders of lower degree. This **hierarchical nesting** of these suborders forms a greater order of its own" (Ibid, p.129).

These somewhat speculative ideas are at least in consonance with:

- 1/ - WEIERSTRASS **renormalization** equation
- 2/ - MANDELBROT's **fractals**
- 3/ - MATURANA and VARELA's **recursivity**

They moreover seem to lurk somehow in the human **brain**, as shown by the existence of the Russian **matrioshka**, the Japanese **kokeshi**, and some of **ESCHER's** engravings.

In the same vein, J. BRIGGS and F.D. PEAT observe that simple and regular order is exceptional in nature... The real nature's **archetypes** seem to be nearer to RUELLE's **strange attractors** and MANDELBROT's **fractals** than to Platonic solids (1991, French translation, p.110).

2380

ORDER FROM NOISE PRINCIPLE^{1) - 2)}

E. MORIN writes: "SCHRÖDINGER, in "What is Life?" stated that ordered **events** could be produced out of two basic principles, the first one "order from order" (**algorithmic**), the second "order from **disorder**" (statistical), from which two types of laws are derived, dynamic laws and statistical ones. Von FOERSTER, in 1959, advanced a third principle, which cannot be confused with the first ones, even if it depends on them: "Order from **noise**" (von FOERSTER

1960, p.31-50). It is a selective principle, according to which **noise-events** contribute to increase order in **complex systems**...

"Von Foerster says that "self organizing systems do not feed only in order, they find also **noise** in their menu." (1960) This Foersterian principle is different from SCHRÖDINGER's **disorder**, which is, *statistically*, order. But the Foersterian principle, as well emphasized by G. GÜNTHER (1962), establishes the synthesis: the "Aufhebung" (overtaking) of order-from-order and of order-from-**disorder** is mechanistic, "order-from-**disorder** is regularity, order-from-**noise** is novelty, or **creativity**" (MORIN, 1972, p.185).

This notion, however, should be received with caution.

R. VALLÉE writes: "... one should not forget that, when **noise** generates order, it is because it has been introduced in a structure otherwise (and already previously) ordered : magnets shaken in a box in von FOERSTER's example, or more simply wheat ears creeping upward in a sleeve under the influence of erratic movements. In von FOERSTER's example, order exist within the highly structured magnetic **interactions** among the magnets; in the case of the ears it surges from their very **dissymmetric structure**. **Noise** does not create order, but it is an excellent *structure displayer*. If order can be thus generated by **noise**, it is by means of an already existing **structure**, possibly not very evident, or under the influence of **constraints**, at times quite unobtrusive. **Noise**, nonetheless, plays a very important role as a **trigger** for the **emergence** of order in what is called *self-organization* or *autopoiesis* of a system"(1990, p.55).

Mac KAY states this in a different, but equivalent manner: "In fact, the badly phrased question: "Is **noise** information?" exemplifies well the need for *semantic hygiene* in the field. The question is incomplete. If translated "Has **noise** selective power?" it invites the immediate rejoinder "On what ensemble?" To specify the ensemble then removes all the **ambiguity** and obviates empty debate" (1969, p.134).

Finally, it seems that the principle of order from **noise** may mainly explain the increase of order which results of the fusion or synthesis of similar or complementary **elements** in an *associative process* which leads to the **emergence** of entities of a superior order of **complexity**. It could be the most basic motor of **evolution**.

2381

ORDER FROM ORDER Principle²⁾

E. SCHRÖDINGER, in his famed work "What is Life?" (1945) established the principle that order (in **living systems**) is somehow transmittable. He stated that "... the final approach to **equilibrium** is very slow. It could take anything between hours, years, centuries". He explained this by the way **living systems** "feed on **nega-**

tive entropy", i.e. maintain their **organization** "by extracting "order" from their **environment**". He describes this "order" as "**entropy**, taken with the negative sign,... itself a measure of order".

This so-called **negentropy** was a **source** of controversy for many years, until it became clear that it simply measures the **level of complexity** (order) in **complex systems**. The final connection with **thermodynamics** is through the creation of order by **dissipative structuration** of **energy** in **far- from- equilibrium** systems submitted to giant **fluctuations**, precisely because of very high **energy inputs**. (BÉ-NARD's **instability**; PRIGOGINE's **thermodynamics** of **far-away from equilibrium** systems).

As proposed by LOTKA with his "**world engine**" model, the **energy** provided by the sun is *slowly* degraded through a "ladder" of systems. Endly, increases of order in some systems must be paid by a correspondingly higher decrease of order in their **environment**.

SCHRÖDINGER's principle has been extended by H.von FOERSTER, precisely in relation to his principle of "**order from noise**". (see above, for critical appraisals)

Its relations with DAWKINS "Selfish Gene" should also be explored. What is transmitted from system to system is not merely order, but better **historical structural** and **functional** order.

→ **Operon**

2382

ORDER (Generative)^{2) - 3)}

"A deeper and more inward order out of which the manifest **form** of things can emerge creatively" (D. BOHM & F. DAVID PEAT, 1987, p. 151).

This is a generalization of the "implicate order" concept formerly introduced by D. BOHM himself: "...a particular kind of generative order that has been most fully worked out in physics" (Ibid).

However, BOHM and PEAT suggest that: "... such a generative order goes far beyond the quantum theory, and is a key feature of the general notion of order that is relevant to understand **creativity** in all areas of life" (3p. 195).

Generative order seems to be in BOHM's idea a kind of universal and global **limit to randomness**. It remains present, for instance, in **deterministic chaos**.

→ **random**

According to BOHM and PEAT, the **concept** is also useful in the study of **social systems**: "The breakdown in the generative order of society is more than mere **decay**... Rather, the rigidity in the generative order constitutes an extremely pervasive and far-reaching blockage of

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

free play of the mind, and this makes for the constant spread of false play and prevents **creativity** that could adequately meet this **situation**" (p.209).

Values could be the form taken by generative order in human societies. But we would need a clear explanation for its breakdown.

2383

ORDER (Generative) and EVOLUTION¹⁾

D. BOHM and F.D. PEAT discuss the **meaning** or generative order in relation to **evolution**. They write: "While the current neo-Darwinian theory is valid in its proper domain, it represents an **abstraction** from a much larger implicate and generative order, and its main significance is to be found in its relationship to this latter order" (1987, p.201).

This is an interesting hypothesis: Nothing is possible outside the basic generative order (for example biological life – at least of the kind we know – would be impossible in a **universe** wherein macromolecules could not be formed). In this sense, generative order is **autopoietic**. However, within the very wide reach of this order, creative **variation** is possible and the **phase space** of **living systems** can expand and finely divide. It ensues that **evolution**, while channeled, is and will necessarily be, a unfinished historic **process**.

Is this something that needs to be proved in the classical sense of scientific "proof"?

2384

ORDER (Implicate)¹⁾³⁾

The hypothesis according to which there is a deeper **level** of order in the **universe** that we can only glimpse in a fleeting way through local and momentaneous **effects**.

The hypothesis has been introduced by D. BOHM (1980) as an **interpretation** of **events** at the quantum level.

Any observed **phenomenon** should be viewed as a "explicate", unpermanent manifestation of the universal implicate order. All **forms** and movements -corresponding to our **perceptions**- would be only transient **fluctuations** of the basic cosmic "fabric" or "**whole**" as a continuum of **energy** whatever this could be

As in many other cases, the explanation generates new question marks. Implicate order could even conceivably signal the end of the road for scientific inquiry

In effect, implicate order carries obvious philosophical undertones and reminds of some pronouncements of hindu philosophy. G. ROUVILLOIS writes the following about SHRI AUROBINDO's **space-time** concept: "The original statute is that of a non-temporal and non-spatial **Reality**. Space and time would be the same

Reality extending herself to obtain the unfolding of what was contained in her. Space and time are the names that we bestow on this self-extension of the one Reality.

"The starting point of AUROBINDO's analysis is the opposition between the unmanifested and manifestation. In a manner, one may say that manifestation belong to a lower **order** of reality than the unmanifested...

"The non-manifest is the non-temporal, the absolutely eternal, an absolute being by itself, on which manifestation and its limitations can give only a limited and deceitful **indication**" (1998, p. 79)

The parallelism with BOHM's view is striking. ROUVILLOIS asks himself: "Is space -time a conceptual **frame**, or a mirror of **brain symmetries**?"

It seems that we cannot finally escape from a lingering doubt about the real **meaning** of "Reality" (with or without a majuscule) and our perceptive **awareness** as the source of "manifestation".

→ **Manifest versus hidden; Ontological skepticism; Present (the everlasting); Quantum Hologram; Quantum vacuum**

2385

ORDER (Local)²⁾

The existence in some region of a system of more strongly interacting **elements**.

Local order corresponds partly to the concept of **frozen components**, or "functionally isolated islands of **elements**" (St. KAUFFMAN, 1993, p.205). It implies a polar relation between global **stability** and **instability** and also a **trade-off** between **coherence** and **adaptability**. Too many **frozen components** tend to reduce **adaptability**.

Local order results of the superposition of some more specific order within a reduced **region**, upon a more general order.

WEIERSTRASS' **renormalization** or MANDELROT's **fractalization** produce local order, which seems to be generally **similar** to the higher order.

2386

ORDER (Optimal)¹⁾

That order which secures for the system the best conditions (in order of importance) of **survival** and **efficiency**, at the lowest **cost**.

Trade-offs between these conditions are possible, but will inevitably lead to a sub-optimal order.

→ **Optimality (Sub-); Optimum; Optimization**

2387

ORDER OR ORGANIZATION?¹⁾

According to J. WICKEN (quoted by R.N. ADAMS): "Biological **structures** are not 'ordered' in the sense prescribed by **information**

theory; they are 'organized' ...whereas ordered systems are generated according to simple **algorithms** and therefore lack **complexity**, organized systems must be assembled **element** by **element** according to an external 'wiring **diagram**' with high informational **context**" (1979, p.353-61).

The "wiring diagram" seems to be a somewhat dubious **metaphor**. The "diagram" is nowhere to be found in living beings or societies, which start at most with **positional values**, and resulting polarizations.

K. DENBIGH'S formulation (also quoted by ADAMS) seems clearer and less inspired from a **mechanicist metaphor**: "... a crystal is more "orderly" than a cell since in the former the atoms and molecules stand in a fixed **relationship** to each other; they repeat themselves at fixed distances... The cell, however, is more organized. DENBIGH does not attempt a final definition of **organization** but does suggest two requirements. One is that of "**complexity**": an organized system necessarily consists of **parts** and **subparts** and these are interconnected" (1988, p.73) (One could say that the **parts** are very **heterogeneous**, as they result from an intense **process of differentiation**).

"Secondly, a further necessary condition for a system to be said organized depends on the notion of **function**... One cannot speak about something being organized without at once raising the **issue**, what it is organized for?" (DENBIGH, 1975, p.85)

In synthesis, order should be considered repetitive, while **organization** is **heterogeneous**, complementary and **hierarchical**.

2388

ORDER PARAMETER^{1) - 2)}

"Global, **macrolevel** parameter which describes the **structures** established in a system" (R. FIVAZ, 1991, p.32).

The order parameter was introduced in the 1940s by the Russian physicist Lev LANDAU.

According to K.DE GREENE's interpretation of H. HAKEN: "The order parameter represents the **macroscopic structure** or **field** emergent out of **interactions** at the more **microscopic level**. The **correlation length** ... is an order parameter. In **phase transitions** order parameters can increase discontinuously from zero (first-order **transition**) in the new **phase**, or they can increase continuously (second-order **transition**). The **emergence** of order is an example of **symmetry breaking**... an important concept in **field theories**...

"The order parameter is a **macroscopic** collective **field**, emergent at **critical points** out of myriad **interactions** at the **microlevel**. (It) expresses stochastic generation of the new (**structural change**) and **deterministic maintenance** of the now established (**structural constancy**). The **emergence** of the order pa-

parameter represents a great loss of **degrees of freedom** at the **microlevel**... (which) now becomes **slaved** to the order parameter" (1994, p.14).

→ **Phase locking**

2389

ORDER PARAMETER APPROACH²⁾ – 3)

The selection of some specific viewpoint or **level** for the study of a system.

R. SERRA and G. ZANARINI state: "The key concept in the 'order parameter approach' is that there are privileged viewpoints for studying **complex systems**. There are alternative **descriptions** which render some aspects comprehensible, while others are useless or frustrating. We can speak of 'comprehensibility windows', i.e. of **description levels** which allow a reasonable treatment of the system, while capturing its essential features" (1987, p.112).

As an example, the authors use **Brownian motion**, that can be viewed at the microscopic, mesoscopic or macroscopic **level**. This approach can be applied to cultural as well as natural systems.

2390

ORDER PRINCIPLE (BOLTZMANN's)²⁾ – 3)

"Systems, in the course of **time**, tend to the most probable **state**, as given by the number of corresponding complexions"

I. PRIGOGINE et al write: "This leads to an increase of the **entropy** *S*, for **isolated systems** or a decrease of the free **energy**, *F*, in **closed systems**" (1975, p.17).

It sounds more as a "Disordering Principle"!

2391

ORDER (Random)²⁾ – 3)

This somewhat paradoxical notion is explained in the following way by D. BOHM and F.D. PEAT: "... a random order can be defined as a special case of a **chaotic** order. It has the following characteristics:

1. It is of infinite degree
2. It has no significant **correlations** or stretches of suborder of low degree
3. It has a fairly constant average **behavior** and tends to vary within a limited **domain**. This **domain** remains more or less constant, or else it changes slowly" (1987, p.127).

The authors state: "This definition of random order accounts well for the distribution of shots from a fixed gun".

However, they recognize that: "... if the **context** is extended, then each shot becomes more nearly predictable. For example, if the wind velocity is measured, or if **variations** in the gun emplacement are observed, then more **information** is available to determine the new **con-**

text and individual **variations** can be calculated. This emphasizes again that the notion of **randomness** is inherently **context-dependent**" (ibid.).

In synthesis, in conformity with **chaos theory**, there is no absolute **randomness** (i.e. **randomness** of infinite degree), nor absolutely predictable order.

2392

ORDER through FIT¹⁾ – 4)

G. BROEKSTRA describes this managerial concept as based on "...the notion of fit or internal **consistency** between core organizational **variables**" and signals that: "Thus, from the beginning the rationality of **equilibrium** became associated (with it). It was understood that **fluctuations** in the form of misfits, **inconsistencies**, paradoxes, or contradictions, had to be dampened or suppressed. In this way, the fit **paradigm** became a unitary approach driving an **organization** towards a particular **stable attractor state (configuration)**. However, although a tight fit may lead temporarily to excellence... paradoxically, in the long run, fit may lead to failure" (1993, p.76).

Maintaining **stability** at any **cost** may not be the correct response when some internal or external condition basic for such a "**stable attractor**" is not anymore guaranteed.

BROEKSTRA explains that in this case: "... a new way of thinking about organizing is called for, one that encompasses this paradox. The old fit perspective does not disappear, but is absorbed into a more comprehensive theory" (p.77).

BROEKSTRA proceeds in his paper to the elaboration of such a theory based on the **chaos** hypothesis of **change**.

2393

ORDER THROUGH FLUCTUATIONS²⁾ – 4)

In PRIGOGINE's words, a "new order principle" may appear "that corresponds essentially to an **amplification** of fluctuations and to their ultimate **stabilization** by the **flow of matter and energy** from the surroundings. He calls this principle "order through fluctuations". An additional important element should be pointed out: "The shaping of a fluctuation of a given type is *fundamentally a stochastic process*. The **response** of the system to this fluctuation is a **deterministic process**, obeying the **macroscopic laws** as long as the system can damp the fluctuations. Now, in the **domain** of formation of a new **structure**, fluctuations are amplified and drive the average values to the new **regime**. Thus, in this **region** the **macroscopic description** in terms of averages breaks down and the evolution acquires an essentially statistical character.

"We have then a picture of a system evolving through **instabilities**: In the **neighbourhood** of a **stable** regime, **evolution** is essentially **deterministic** in the sense that the small fluctuations arising continuously are **damped**. But near a **transition threshold** the **evolution** becomes a **stochastic process** in the sense that the final **state** will depend on the probability of creating a fluctuation of a given type. Of course, once this probability is appreciable, the system will eventually reach a unique (apart from small fluctuations) **stable state**, once the **boundary conditions** are specified. This **state** will then be the starting point for further **evolution**" (1973, p.587-8).

E. JANTSCH writes: "...PRIGOGINE shows for the physical **domain** that partially **open systems** in a **state** of sufficient **nonequilibrium** (so-called **dissipative structures**) try to maintain their capability for **energy** exchange with the **environment** by switching to a new **dynamic regime** whenever **entropy** production becomes stifled in the old **regime**. This is the principle of 'order through fluctuation' which reverses some of the dynamic characteristics holding for **closed systems** and **systems near equilibrium**" (1976, p. 38-9).

Let us remember that in this work we prefer to use the term '**isolated**' instead of '**closed**' for abstract **models** of systems to which the **2nd Law** is applicable without any restriction.

JANTSCH adds: "In particular, order may increase (whereas in **closed** or **near-equilibrium systems**, according to the **second law of thermodynamics**, it can only change toward greater **disorder**), and the response to **fluctuations** (which may themselves be **random**) is the less **random** the more **degrees of freedom** the system has" (p.39).

This is probably the basic reason for some very fundamental effects we are presently witnessing in contemporaneous societies, as:

- an **exponential growth** of **energy** consumption
- more and more violent economic, ecological and social **fluctuations**
- the appearance of evermore complex organizational **structures** (as for example numerous megalopolis)
- the enormous increase in the production of **waste** of all kinds.

Remains to be seen if a more global planetary system of higher **complexity** will emerge.

An intriguing relation with GRASSÉ's **stigmergy**, is considered by PRIGOGINE, who, in relation to GRASSÉ's concept considers that any originally **random fluctuation** may become the **original nucleus** for **dissipative structuration**. This provides a connection with the **model of order from noise**.

²⁾methodology or model

³⁾epistemology, ontology and semantics

⁴⁾human sciences

⁵⁾discipline oriented

2394

ORDINALITY²⁾

The logical **level** of a certain **order** of **complexity**.

Ordinality is a basic **concept** of RUSSELL and WHITEHEAD's **Theory of Logical Types**, which solved the paradoxes resulting precisely of the mixing of different logical **levels**.

2395

ORGAN²⁾

The **set** of "all the **components** which carry out the **processes** of a given **subsystem** of an **organism**" (J.G. MILLER, 1978, p.315).

The organ is the second **level of complexity** in MILLER's **taxonomy of living systems**. It is made of **cells** and has a defined structural and functional role in an **organism**.

MILLER comments: "This is like one common **meaning** of organ, "a part of the body having a special **function**" and different from another current usage, "a more or less independent portion of the body having a tissue framework, and a special blood, lymph and nerve supply in addition to its characteristic essential **cells**" (Ibid).

2396

ORGANICISM³⁾

An epistemological attitude which tends to consider the **organism** as a legitimate **level of understanding**, as opposed to a **reductionist (mechanistic)** attitude which aims to explain the properties of the **whole** through the ones of its **elements**". (E. SCHWARZ, 1993, p. 10)

A quite different definition, of a neat metaphorical nature is also given by SCHWARZ: "social philosophy of the 19th C. according to which the social body works like an **organism**, i.e. as a coherent whole, whose every **part** carries out some **function** needed to the whole" (Ibid)

This last view is as old as the Roman parable about "the members and the stomach" and, while basically acceptable to begin with, is surely also a **mechanistic** and excessively simplistic view of societies (even the lower organisms one)

In short, organicism is in effect an "epistemological attitude" that should be scrutinized closely when applied.

However, organicism led biology out of its vitalist dead end and is also at the roots of systemics

Organicism appeared at the beginning of the 20th Century in the field of biology., (J.H. WOODGER and L.von BERTALANFFY), as a reaction against **mechanicism**, as well as **vitalism**.

Organicism, which is interested in the global properties of **organisms**, as supplementary to the properties of their **parts**, became through von BERTALANFFY's influence, one of the original roots of **systemics**.

2397

ORGANICISM (BAHM)³⁾

A. BAHM has proposed a general concept of organicism, i.e. not limited to biology, in the following terms:

"... it centers about a concept of "organic unity"... organicism incorporates emergentistic ideas about **holons** as loci of integrative tendencies conducive to the **emergence** and maintenance of larger **wholes** and higher **levels of organization**... It holds that sometimes the tendencies in **parts** to unite in a larger **whole** are stronger, and sometimes the tendencies of a **whole** to unite its **parts** are stronger. When these two kinds of tendencies cooperate, **integration** is facilitated; when they compete, **integration** may be retarded...

"Organicism concedes to **structuralism** that when organicism attributes organic **wholeness** variably to all existing system, the universal presence of such organic **wholeness** may be regarded as a structural **invariant**" (1984, p.207).

2398

ORGANIGRAM²⁾

The general plan of an **organization**.

This would be a neologism in English, as the word is in fact a French one (also adapted in Spanish).

An organigram is generally represented as a static chart, or **graph** representing the **structure** (generally a **tree**) or as a **flow chart** (when representing the **set of operations**).

2399

ORGANISM^{2) - 5)}

A coherent **set** of structured biological **elements** able to fulfill **processes** and **functions**.

This is the third **level of complexity** in J.G. MILLER's **taxonomy of living systems**. Organisms are made of interconnected **elements** ordered in **structures** (like **organs**) and able to carry out interdependent **processes**, producing a global behavior. MILLER also classifies as organisms **colonial living forms** and multicellular **structures**, as for example slime molds, when in their aggregated state. (See "**dictyostelium discoideum**").

N. RASHEVSKY gives a more formal definition: "...a system which satisfies a prescribed **set** of n-ary **relations** or, in other words, which is described by a **set** of n-placed predicates that are characterized by specified properties".

This author adds a caveat: "The **choice** of the system of such predicates still remains, however, to a large extent, arbitrary" (1967, p.21).

RASHEVSKY states: "A social organism is a **set** of individuals... A multicellular biological organism is a **set** of **cells** and... a unicellular organism may be considered as a **set** of genes" (Ibid).

An organism may thus be a **living system**, or a system of **living systems**.

G. PASK states: "... when we speak of an organism, rather than the chemicals it is made from, we do not mean something *described by* a **control system**. An organism *is* a **control system** with its own **survival** as its **objective**. The basic **homeostasis** is to preserve itself as an individual... To survive in changeable surroundings an organism must be an **adaptive control system**" (1961a, p.72).

This concept, first proposed in 1961, is closely related to **autopoiesis** and **autonomy**, as can be seen in the following quotation from PASK: "The overall **homeostasis**, preserving the organism, can be expressed as the conjoint action of many **homeostatic** systems, each preserving a **structure** or condition needed for the functioning of the others" (p.73).

It is now commonly admitted, as stated by V. CSANYI, that an organism "... is a more or less autonomous **network** of **components** and **component** producing **processes** which is replicating in **time**... As a unity it is also a **component** of higher **organizational levels**, like **ecosystems** or the whole **biosphere**" (1993, p.264).

This view is close to the **organizational closure concept** as well as to **connectionism**.

→ **Auto-genetic system precursor**

2400

ORGANISMIC³⁾

Character of any **model** based on an **analogy** with living **organisms**.

"Organismic is used to describe a **relationship** between individuals such as their **autonomy** and **identity** are in part absorbed or entrained by the **interactions** which form a greater **whole** of which they are "**components**" insofar as the communicative **sets** are concerned" (F. ROBB, 1990, p.139).

ROBB applies the **concept** to human **organization**, but its origin is – as well known – biological. Thus, more generally we may replace "individuals" by "constitutive **elements**".

2401

ORGANISMIC ANALOGY⁴⁾

In a paper presented at the Annual Meeting of the Association for Politics and the Life Sciences (Montreal, Canada, Aug. 2002) Peter CORNING writes:

"The so-called "organismic analogy" which has graced social and political theory (off and on) ever since Plato, has reemerged in evolutionary biology in recent years as a way of characterizing key properties of social **organization** in the natural world although the preferred moniker these days is Herb SPENCER's term "**superorganism**". Biologists often give credit to one of their own, William Morton WHEELER, but Wheeler's writings appeared several decades later. As Spencer himself argued, the organismic analogy is justified by the existence of common functional properties at "higher" **levels** of biological organization, including especially "functional **differentiation**" and "**integration**" with respect to the pursuit of overarching, "collective" **goals** or objectives; there is a functional commonality between **organisms** and superorganisms. But more important, superorganisms may also constitute a distinct unit of **selection** (and adaptive **change**) in the evolutionary process. In accordance with the so-called "Synergism Hypothesis", the combined functional **effects** that are produced by social "**wholes**" are the primary causal agency underlying the evolution of **cooperation** and **complexity** in nature. It is the **synergies** (the economic payoffs), broadly speaking) that are the drivers for evolutionary **complexification**... (A number of illustrations will be provided, including bacterial colonies, social insects, symbiotic partnerships and social mammals). Without exception, however, superorganisms are also dependent upon **cybernetic (communications and control) processes**, or **governance**. Accordingly, human superorganisms (and their "political systems") are not sui generis but are variations on a major evolutionary theme... Indeed, it is likely that social organization played a key part in human evolution, and in the rise of civilization. (the accumulating evidence will be briefly reviewed in this paper.) A modern human society represents an elaboration upon an ancient hominid **survival strategy**. It is, quintessentially, a "collective survival enterprise." This perspective casts a different light on the ongoing process of cultural evolution and the much-debated prospects for global governance, or political "devolution" or both. Paradoxical as it may seem, the current, dualistic trend toward both more and less inclusive superorganisms may continue as the economic and political topography and the functional needs for governance continue to evolve. Accordingly, a global superorganism may well be emerging even as traditional nation-states are devolving. The history of the European Union suggests that an explicit "vision" of a global superorganism can serve as an important motivator and catalyst for this process. However, this is only the beginning. To quote the distinguished 20th century evolutionary biologist,

Theodosius DOBZHANSKY: "The future is not vouchsafed by any law of nature, but it can be striven for."

→ **Co-evolution; Morphic field**

2402

ORGANISMIC BIOLOGY ¹⁾²⁾⁵⁾

A set of new concepts about the nature of living **organisms** that was introduced between 1920 and 1940 by a number of biologists as an alternative theory of life, as opposed to **reductionist mechanistic** concepts as well as **vitalists** ones

The basic tenet of organismic biology is that life cannot be understood without a general integrative view of the internal **organization** of the organism, i.e. the existence of **functional** and **structural interrelations** between its constitutive **elements**. Thus "the whole is more than the sum of its **parts**"

F. CAPRA writes: "Since these organizing relations are patterns of relationships immanent in the physical structure of the organism, organismic biologists assert that no separate, nonphysical entity is required for the understanding of life..."...the concept of organization has been refined to that of self-organization in contemporary theories of living systems" (196, p. 25)

→ **Autopoiesis**

2403

ORGANISMIC SET ^{2) - 4)}

"A mathematical entity that has properties common to both biological and social **organisms**" (N. RASHEVSKY, 1967, p.21).

RASHEVSKY, who introduced the concept, gives the following examples: "A social **organism** is a **set** of individuals who are the **elements** of the **set**. A multicellular biological **organism** is a **set** of **cells**; and... a unicellular **organism** may be considered as a **set** of genes..."

"Moreover, in all organismic sets, that is, in both biological and social **organisms**, the **elements** of the set replicate or multiply..."

And: "An organismic **set** of **order** *n* is a set whose **elements** are organismic **sets** of **order** *n - 1*".

RASHEVSKY finally claims that "The theory of organismic sets forms a sort of conceptual superstructure over biology and sociology" (p.21, 22, 27).

2404

ORGANIZATION ^{2) - 4)}

1) The **set** of actual or possible **interrelations** between the **components** of a system.

(or, for human organizations) "The entire **set** of **relationships** it has with itself and its **stakeholders**" (I.I. MITROFF and H.A. LINSTONE, 1993, p.142).

2) A system made of interconnected functional **elements** or **subsystems**, generally in various **hierarchical levels**.

H. Y. LERNER, quoted by J. ESPOSITO notes that: "The concept of organization is very difficult to define accurately, but from **intuition** it is clear that organized systems are far from being in "**thermodynamic equilibrium**". For instance, a gas consisting of molecules moving at **random** can be considered as having a zero degree of organization, whilst **organisms** capable of maintaining their existence and reproducing themselves have a high degree of organization" (1972, p.8).

J.L. ESPOSITO comments that, lacking **equilibrium**, organizations must necessarily engage in exchanges with a specific **environment**. He adds that: "In nature there may be nothing corresponding to a zero degree of organization, for an unconfined gas, like a frictionless surface, may remain only a theoretical ideal. From these remarks, then, it is clear that **closure**, **control** and **exchange** are necessary conceptions in any definition of organization" (1975, p.134).

And still: "An organization will be seen to constitute a balance between activator and inhibitor factors corresponding in general to the contrast between **negentropy/information-gain** and **entropy/information-loss**. In such a contrast can also be found the dual and biperspective nature of organization as both **object** and **process**" (p.135).

2405

ORGANIZATION (MILLER) ⁴⁾

"A system with multiechelon deciders whose **components** and **subsystems** may be subsidiary **organizations**, **groups** and (uncommonly) single persons" (Adapted from J.G. MILLER, 1978, p.595).

This is, in MILLER's **taxonomy of living systems**, the level that supersedes the **group**.

MILLER states: "Organizations are **subsystems**, **components**, or subcomponents of **societies**, sometimes more than of one **society** (p.595).

2406

ORGANIZATION: A descriptive language ¹⁾

J.L.R. CHANDLER proposes the following four descriptive concepts relative to the **behavior** of any degree of **organization**:

Closure: a **domain of discourse**, a **category**, a system, an **object**, unity

Conformation: the **components** of the closure of a system, the internal **patterns** of the system, the **relationships** among the **parts** of the system, a three dimensional depiction of the internal **description** of the system, a specific geometric and algebraic **description** of **components** of the system

Concatenation: binding **parts** together, linking changes in the conformation, changes in the internal **patterns** of a system, the specific **link-ages** between parts of the **whole**, **dynamic processes** of the system linking patterns to patterns

Cyclicity: a pattern of concatenations which sustain the system, the potential **cyclic walks** or **pathways** over the conformations of the system, the habitual **behavior** of the **closure**.

"These four concepts serve as the basis for a linguistic **description** of simple and complex material systems. In principle, each concept can be applied to the enumeration of each degree of **organization**..."

"These four terms are interdependent with each other and must be defined sequentially" (1998, p. 20)

This last comment explains why some of these definitions are not given separately in the Encyclopedia.

2407

ORGANIZATION as a pattern ²⁾

Organization may be understood as a **pattern** (in contrast to **random distribution of elements**):

- either in **space**, as a stable **structure**
- or in **time**, as a changing **structure**

E. MORIN proposes three different types of organization, understood as a **process** evolving in **time**:

- **Re-organization**, which expresses **diachronic transformation**;
- **Self-organization**, which corresponds to **closure** of the system by **recursion**, and **autonomy**;
- **Eco-organization**, which expresses the systems openness on its **environment** (after MORIN, 1990).

2408

ORGANIZATION as a process of progressive mechanization ¹⁾

According to L von BERTALANFFY: "At first, systems – biological, neurological, psychological or social – are governed by dynamic **interactions** of their **components**; later on, fixed arrangements and conditions of **constraints** are established which render the system and its **parts** more efficient, but also gradually diminish and eventually abolish its **equipotentiality**" (1956, p.5).

This reduction of the **degrees of liberty** of the relations among **components** leads to their grouping in a limited number of structural and functional **subsystems**, i.e. to the **heterogeneity** proper to **complex systems** and to the establishment of functional **algorithms**. These latter can be very rich, but are nevertheless quite limited when compared with the original potential of the system. It is thus apt to speak of mechanization.

2409

ORGANIZATION as a system ^{1) – 4)}

So many definitions have been given for "organization" in so many different senses that it seems convenient to qualify different **meanings**

C. ARGYRIS gave the following descriptive definition:

"An organization is a plurality of **parts**, each:

1. achieving specific **objective(s)**;
2. maintaining itself through interrelatedness with the other **parts**;
3. simultaneously adapting to the external **environment**, and;
4. maintaining thereby the interrelated **states** of the **parts**" (1959, p.124).

These characteristics are of course describing a "**whole**" or a "**system**".

According to W. BUCKLEY a "morphogenic" **model** of the organization would be useful to emphasize its progressive build up as it emerges from the **interaction** of the **elements** and the **flow** of **information** among them.

F. ROBB considers that: "Organizations are **social systems** purposely **designed** and constructed by men to achieve specific **goals** and to perform some explicitly defined **functions**. They are defined *initially* by their human **designers**, and, at least *in principle*, are **controllable** systems" (1993, p.3 – Italics by this compiler).

As human organizations imply a great **variety** of necessary, recommendable, merely tolerable or downright forbidden **interactions**, they are based on **rules** of conduct, either tacitly known and admitted, or legally stated and recognized by their members. Some of these **rules** are prescribing the **behavior** of the members within the organization, while others are directed at the **interactions** of the organization and its members with other systems, or the **environment** in general.

ROBB adds: "... at the **macroscopic level** the institution expends much more lifetime in sustaining itself. It does this by employing its **distinctions**, **values** and definitions in **communications**, by ritualizing the reiteration of its sacralised "**truths**", and by collecting anomalies and **ambiguities** arising from incoherent and inconsistent **conversations** and **actions** for redistribution as "**problems**" to be solved by further **conversations**" (p.4).

These views are synthesized by J.van GIGCH, according to whom "The organization is an **information** system which functions like an Intelligent **Artifact**" (1993, p.52).

Practically, organizations acquire promptly their own systemic logic and a degree of **autonomy** respect of their **designers**, become more or less unpredictable and even, sometimes, lead them to some unforeseen **situations**, as their **control** turns illusory. This implies that **design** must be a reiterative **process**.

2410

ORGANIZATION (Autopoietic) ^{1) – 2)}

"The **invariant** relations that hold between the **components** of a composite unity of a particular kind" (H. MATURANA, 1979, p.23).

The autopoietic form of organization is fundamentally different from the **allopoietic** one.

M. ZELNY resumes in the following way MATURANA and VARELA's work: "Autopoietic organization is realized as an **autonomous** and self maintaining unity through an independent **network** of **component-producing processes** such that the **components**, through their **interaction**, generate **recursively** the *same network* of **processes** which produced them. The product of an autopoietic organization is thus not different from the organization itself. A **cell** produces cell-forming molecules, an **organism** keeps renewing its defining **organs**, a social **group** "produces" **group**-maintaining individuals, etc. Such autopoietic systems are **organizationally closed** and structurally **state-determined**..." (M. ZELNY, 1977, p.13).

This means that the organization (or system) maintains its **identity**. However the system, while **organizationally closed**, is *not isolated*, because this being the case, its **survival** would be impossible, in accordance with the **2nd law of thermodynamics**.

Moreover, the autopoietic organization uses **inputs** from its **environment** to maintain itself, but also transform some of these **inputs** to produce specific **outputs**.

As stated by ZELNY, the **allopoietic mode** of organization is characterized by the fact that the system does not produce its own **components**, nor possesses the **processes** to produce them. "Thus, **allopoietic** systems are not perceived as "living" and are usually referred to as **mechanistic** or contrived systems... For example, spatially determined **structures**, like **crystals**, or macromolecular chains, **machines**, formal **hierarchies**, etc., are **allopoietic**" (Ibid).

2411

ORGANIZATION (Characteristics of) ²⁾

BERTALANFFY stated (1956) "Characteristics of organization, that of a living **organism** or a **society**, are notions like those of **wholeness**, **growth**, **differentiation**, **hierarchical order**, **dominance**, **control**, **competition** and so forth" (1956, p.7).

He noticed that: "Such notions do not appear in conventional physics" (while) "Systems theory is well capable of dealing with these matters" (Ibid).

He gave as examples of specific systemic theories those about biological **equilibria**, **cyclical fluctuations** and others introduced by

LOTKA, VOLTERRA, GAUSE and more authors and signaled their probable **isomorphy**, at least partial, with certain quantitative theories in economy.

2412

ORGANIZATION (Characteristics of a human)^{2) - 4)}

According to R. ACKOFF "The four essential characteristics of an organization can be briefly identified as its: a) **content**, b) **structure**, c) **communications**, and d) **decision-making (choice)** procedures" (1960, p.3).

It is this last point that identifies human organizations, as different from those defined by BERTALANFFY

ACKOFF states in a more detailed way:

"1. Some of its **components** are... human beings. Wires, poles, switchboards and telephones may constitute a **communication** system, but they do not constitute an organization...

"2. Responsibility for **choices** from the **set** of possible **acts** in any specific **situation** is divided among two or more individuals or **groups** of individuals... a) by **function** ... b) by **geography** ... c) by **time**....

"3. The functionally distinct subgroups are aware of each other's **behavior** either through **communication** or **observation**...

"4. The system has some **freedom of choice** of both **means** (courses of **action**) and **ends** (desired outcomes) (p.2).

How these characteristics show through in specific **parts** of an **organization** is described for example as follows by H. MINTZERG (1979) who identifies the following ones:

- the operating **core** where **tasks** are centred around the actual production of goods or services
- the strategic apex where top **management functions** are carried out
- the middle line which links the **strategic** apex to the operational **core**
- the technostructure where the **structure** and **processes** within the **organization** are planned, organized and re-organized
- the support staff which supports the functioning of the operational core"

2413

ORGANIZATION (Coherent)¹⁾⁴⁾⁵⁾

J. WARFIELD (pers. comm.) defines coherent organization in a most general way as "a virtual organization, furnishing a **context** in which **complexity** is very often located, and wherein it must usually be dealt with, if **resolution** of complexity is desired".

This is in fact a practical consequence- and should be a practical application- of ASHBY's **Law of Requisite Variety**

A frequent drama is that the implicit incoherence of a given organization becomes evident only when some unforeseen crisis or **disaster** emerges.

It is of course a result of what Warfield himself describes as **underconceptualization** in the minds of the managers of the organization.

It is in fact a **model** of **meta-organization** through which the different levels of an organization, or the **interrelations** between a number of different organizations can be described.

This should be in fact a practical application of ASHBY's **Law of Requisite Variety**

WARFIELD comments: "It is even possible that the inability of the individual to comprehend complexity, imprisoned by a constraining institutional setting, is responsible for what has been described as a "flight from science and reason". (P.R. GROSS et al.) and for ascendancy and popularity of management gurus"(J. MICKLETHWAIT & A. WOOLDRIDGE)

WARFIELD explains: "The coherent organization is a virtual organization with three organization levels. Any conventional organization can be thought of as a changing collection of such virtual organizations".

He distinguishes a Level 3, the producing level..."in which goods and services are produced". Most of the **population** of the organization belongs to this level. Level 1 is "the **strategic** level, the level in which broad **goals** are enunciated, where most of the authority lies, and where the **survival** and **growth** of the organization is pondered". It is in fact the "managers level".

"The intermediate level, Level 2, is the Mediating Level. At this level, the Level 3 activities and the Level 1 strategies are mediated.

In order for this **mediation** to be effective, people in the Mediating level (let us call them "middle managers") must be aware of what is happening at both the lower and the higher level"(pers.comm.). The level 2 people must convey the general vision elaborated by level 1 people to the producers at level 3.

They must also convey the practical realities faced by level 3 people to managers at level 1. All this is in fact a **feedback network** between levels.

2414

ORGANIZATION (Cost of)¹⁾

The **maintenance** cost of organizations in terms of needed **energy inputs**, grows accordingly to their **complexity**, i.e. to the number of the interconnecting pathways among their **components**, **elements** or **compartments**.

According to H.T. ODUM "... the potentialities for diversity are related to the **energy** budget in... square **functions**" (1983, p.216).

Moreover, A. UYEMOV links organization with disorganization: "the origin of disorganization is linked with the **growth** of organization in another system" (1975, p.95).

If so, **useless complexity**, i. e. the creation of non-functional links between **components**, should be avoided (as for example in **overburdening** bureaucraties, or **controls**).

2415

ORGANIZATION (Emergent levels of)^{1) - 2)}

More complex levels of organization do emerge by **structuring dissipation processes**, which appear in systems submitted to giant **fluctuations** that finally destroy their **steady state** and **dynamic stability**.

The **process** is however still somewhat enigmatic.

In most cases, emergent organization seems to arise from the ordering of numerous **lower level elements**, which become the building blocks of the **higher order whole**.

Such a **process** must be at work when molecules become ordered in crystals or in polymers, or when **cells** become arrayed in tissues and **organs**, or when insects or people as individuals become participants of complex **social systems**.

2416

ORGANIZATION (Epigenetic evolution of)^{1) - 2)}

According to J.P. CHANGEUX, in biological **evolution**: "... at the higher **levels** of organization... there is also a so-called epigenetic **evolution** in the individual, without modification of the genome. The varying **elements** are the neurons: their number and, most of all their **interconnexions**" (1992, p.707).

"At the highest **level**, "reason" links between groups of neurons do appear, **programs** of action and reasoning do develop" (p.706).

It seems to be a constant of **evolution** that, at some states, higher **levels of complexity** emerge *through association* of **elements** of the immediately lower **level**. C. BRESCH, tackled this subject globally in his book "Zwischenstufe Leben: Evolution ohne Ziel?" (1977).

BRESCH describes the following **levels** of organizational **emergence** through **association**: Atoms from elemental particles; molecules from atoms; polymers from molecules; protobionts from polymers; **cells** from protobionts; pluricellular **organisms** (plants and animals) from **cells**; **groups** from animals. In a similar fashion CHANGEUX shows the **emergence** of neurons from atoms through **association** between neurotransmitters, neuropeptides, enzymes, etc.; and the **emergence** of the highly organized **brain** through **association** between **groups** of neurons.

A similar **emergence phenomenon** seems presently at work among men and may signal the **emergence** of a planetary super-**organism**. **Association** between simple **robots** could seemingly also lead to societies of cybernetic **organisms**.

2417

ORGANIZATION (General Theory of)^{1) - 3)}

According to K. BOULDING: "The general theory of organization begins with the concept of **homeostasis**; that is of a **mechanism** for stabilizing a **variable** or a group of **variables** within certain **limits** of tolerance. Every **organism** or organization is characterized by a group of such **variables**, and the organization consist mainly in more or less elaborate apparatus to maintain these **variables** between an upper and lower **limit**. Should any of the essential **variables** rise above the upper **limit**, machinery must be brought into play to reduce it; should it fall below the lower **limit**, machinery must be brought into play to raise it. An organization in this view consist of an **aggregate** of such governing **mechanisms** sometimes called **control mechanism** or **feedback**" (1952, p.36).

A **feedback** is not really per se a **control mechanism**, but only an essential **part** of it.

Moreover this formulation (dated 1952) does not escape from the critique of "**mechanistic reductionism**" that has been frequently directed at WIENER's **cybernetics**. Nearly all the important contributions of ASHBY, von FOERSTER, MATURANA, MARUYAMA, and many others did appear after 1952.

According to Rafael RODRIGUEZ DELGADO (1997, p.25) a General Theory of Organization should cover the following subjects: "**Wholeness, growth, differentiation, hierarchical order, dominance, control, competition and teleology**, whose **parameters** are not easily measured... Moreover, organization implies a **configuration of interrelations (communication, information)**, ordered and coherent, of the inside of the systems and of groups of systems"

The growing use of **networks** to explain intelligent structures or to construct them (see "**connection machine**") brings now a still newer dimension to our **concept of organisation**.

2418

ORGANIZATION ("Good")^{1) - 2)}

Basing himself on a comment by ASHBY according to which the properties of **constraints** "are not intrinsic to the thing but are relational between **observer** and thing" (1968, p.109), W.R. WINBURN states: "This means that no organization can be good, useful, functional, etc., in any absolute sense; rather, such qualities are relative to the **context** or viewpoint of the **observer**. Yet, for any given **context**, we find that good organization is of the nature of a relation between the **set of disturbances** and the system's **goals**" (1991, p.562).

"Good" seems here to express **fitness**. Still, our **appreciation** of fitness is always an **observer's** view. However, systems, well or ill organized, survive or perish independently of

their **observers**. We need thus to sharpen our **observation** in order to limit discrepancies between what we see as "good" or "fit" and what it may be for the **concrete system** we are interested in.

2419

ORGANIZATION (Hetero-)²⁾

According to E. PESSA: "It is commonplace ... to speak of **self-organization processes**, but it would be better to speak of hetero-organization; that is, the **control parameters** are driven by the external **environment**, without any possibility for the (dynamical) system to counteract this influence" (1992, p.434).

This means that the system is self-organizing only as far as such **process** remains compatible with the **environmental** basic conditions. An oxygen-breathing **living system** cannot anymore organize itself if its **environment** becomes suddenly devoid of oxygen.

Without reaching such an extreme case, the system "... can ... follow, in a passive way, the **behavior** of the external **fluctuations**, whose role, on the other hand, is only that of making explicit the richness of dynamic **behavior** implicitly contained ... in the **form** (of the system)" (Ibid).

In other words, as stated by von FOERSTER, **noise** can be a **source of order** for a dynamic system.

2420

ORGANIZATION (Holographic)^{1) - 4)}

Inspiring himself from several sources, J. JOHANNESSEN proposes the following requirements and **criteria** of a holographic or **heterarchical** organization:

1. The **whole** enclosed in its **parts**
2. **Double-loop learning** (deutero-learning), with communicative **competence**
3. Fewer **levels of management**
4. Liquidation of a centrally managed **command and control model**
5. The transition to a "flatter" organizational **structure**
6. Clearly defined **goals** leading to **action**, where the results, plans, and **goals** can be evaluated explicitly
7. More emphasis on individual responsibility for contact and **communication**
8. More emphasis on the overall view
9. Organizational **design** favoring innovations and **autonomy**
10. The gathering of **information** a more distributed **process**
11. The transition from **data** processing to complete **information** systems.
12. **Flexibility** and freedom for the individual members of the organization
13. Involvement by all in the **planning process**
14. Creating the future, not predicting it

15. **Cybernetic** principles as the foundation for organizational **design**

16. **Self-organizing, autonomous** small **groups**

17. Global **information** can be taken out locally and local **information** can be taken out globally. In holographic terms: each **part** of the organization contains enough **information** to recreate the **whole**" (1991, p.41-42).

Such a proposal seems viable only if the cultural conditions (i.e. the **environmental meanings** and **values system**) supports its sub-jacent postulates, which is surely not the case in several cultures, where personal responsibility is not strongly recognized,, or is recognized merely within an authoritarian **frame**.

2421

ORGANIZATION (Law of optimum size of an)^{1) - 4)}

"The larger an organization grows, the longer is the way of **communication**, and this, depending on the particular nature of the organization, acts as a limiting factor and does not allow an organization to grow beyond a certain **critical size**" (L.von BERTALANFFY, 1956, p.7).

This law, stated by BERTALANFFY was enounced by K. BOULDING. It applies in depth as well as in extension. The geographical extension, for example, that an organization is effectively able to embrace and maintain depend on the nature and importance of its **communication means** and of its capacity to maintain the corresponding **net** in good functional state. It is also the case with any internal **communication net**, not anymore in a geographical sense, but from the viewpoint of its **density**. In the first case, disruption risks appear due to excessive stretching beyond some **limit**, or because of a growing **noise** in the **channels**. In the second case, there is a risk of **overcrowding** and overtightening, due to **competition** between too numerous **elements** which try to use simultaneously a **net** whose capacity is saturated or exceeded.

2422

ORGANIZATION (Levels of)^{2) - 4)}

According to R. ROSEN, a system is "... **hierarchically** organized if it satisfies the following two conditions: a) the system is engaged simultaneously in a **variety** of separate distinguishable **activities**, and b) different systems **descriptions** are necessary to describe these several **activities**. It is this second condition which characterizes biological systems, with their stratification into many **levels** of organization" (1972, p.59).

A good example of organization through levels is given by J.P. CHANGEUX, describing the successive levels of neural organization in the **brain**:

- individual **connections** between neurons
- elemental **circuits** of a reduced number of neurons in charge of specific reflexes **functions** (walking, swimming, bicycling, etc.)
- more complex **clusters** of associated neurons able to codify more abstract **representations**
- **clusters of clusters**, corresponding in the human **brain** to the highest mental abilities: reasoning, **planning**, etc. (1992, p.706).

There appears to be a progressive **algorithmization process** at different levels.

One may wonder if the same type of **processes** is not a general feature of **emergent** social **organization**. It seems to characterize the present **process** of globalization of human **social systems**.

see figure below

2423

ORGANIZATION (Levels of) according to J. MILLER^{1) - 2) - 4)}

In his "Living Systems" (1978), MILLER introduced seven levels. Later on, he added the "**community**" level, in-between the "**organization**" and the "**society**" (1990, p. 158).

MILLER's **taxonomy** of levels of **organization** refers to **living systems**. It thus excludes physical ones, as for instance the solar system. Its **meaning** is different of, but not incompatible with LE MOIGNE's **nine levels** (see hereafter)

Figure: see entry ORGANIZATION (Levels of)

Organization levels: An ecological example

From C. FRANÇOIS: 1987, p. 71

MILLER's levels are ordered with reference to their growing **complexity**. They are:

- the **cell**, composed of different interacting organelles, as nucleus, mitochondria, ribosomes and Golgi apparatus;
 - the **organ**, internally organized as composed of different classes of **cells**;
 - the **organism**, a globally organized complex of various types of interacting **organs**;
- These are the three purely biological **levels**.

The next five ones are sociological;

- the **group**, a reunion of **organisms**, endowed with different capabilities and collaborating in pursuit of some common **goal**, as a family;
- the **organization**, a **group of groups**, also endowed with specialized capabilities, and pursuing a global **goal**, in need of a good coordination of specific sub-goals, as an industrial plant;
- the **community**, a complex of **organizations**, seeking still more general and complex **goals**, as a city;
- the **society**, an articulated complex of **communities**, with global meta-goals, as a nation;
- the **supra-national system**, with **goals** common to various national societies, as the European Union, or the United Nations Organization.

It would be interesting to find out the possible application of some similar **taxonomy** to insect societies, for example, or to **ecological communities**.

2424

ORGANIZATION (Modes of)²⁾

J. FEIBLEMAN and J. FRIEND classify organizations as **wholes** into various kinds. They write: "The kinds of organization constitute degrees of integrality, as follows:

a) **Agglutinative**: the governing **relation** is **aseriality**, where **parts** have **intransitivity**, **connexity** and **symmetry**.

b) **Participative**: the governing **relation** is **seriality**.

Participative organizations subdivide into three kinds, as follows:

a) **adjunctive**: The governing **relation** is **symmetrical independence**. The sharing of **subparts** is not necessary to either of the **parts**. **Parts** can survive their separation.

b) **subjective**: The governing **relation** is **asymmetrical dependence**. The sharing of **parts** is necessary to one of the **parts**, but not to both.

c) **complemental**: The governing **relation** is **symmetrical dependence**. The sharing of **parts** is necessary to both of the **parts**. Neither **part** can survive separation..." (1969, p.36).

The authors observe that: "The division of organizations into various kinds is not arbitrary, although there are other classifications that could be made. The present one is made specifically according to the governing **relations** of the organizations. It needs to be pointed out that this classification is ideal in the sense that no actual organization ever completely answers to it" (1969, p.36).

2425

ORGANIZATION of a SYSTEM^{1) - 2)}

According to G. KLIR: "If the system is to exhibit a particular **behavior**, it must possess... certain properties which we call the organization of the system. Since, according to the definition given, the **behavior** of the system can change (from the viewpoint of local **relations**), we must assume that its organization can also change. It will be of advantage to define the constant and the variable part in the organization of the system" (1965, p.31).

This is a quite classical **structural** and **functional** view of organization in systems. It should be compared with the ulterior **autopoietic** understanding of **organizational closure**, according to which organization is a **cyclical** (M. EIGEN would say **hypercyclical**) property of the system as a **whole**.

A closely related view is also offered by the **autopoiesis** concept. In M. ZELNY's words: "A **network of interactions** between the **components**, renewing the system as a distinct unity, constitutes the organization of the system. The actual spatial arrangement of **components** and their **relations**, integrating the system temporarily in a given physical milieu, constitutes its **structure**" (1984, p.13).

¹⁾general information

²⁾methodology or model

³⁾epistemology, ontology and semantics

⁴⁾human sciences

⁵⁾discipline oriented

There are however some dubious cases, as for example petrified wood, which is not anymore wood, but has for eons conserved through chemical **transformations** the organization (or **structure**?) of the original system.

As to the constant and the variable **parts** in the organization, it is, at least for practical purposes, a matter of the **time scale of observation**.

2426

ORGANIZATION, ORGANISM: A semantic comment³⁾

R.W. GERARD tried to put some order among the **meanings** of different words related to the concept of organization (1950).

He wrote: "The word 'organism' has been used in two senses; a more specific one, referring to living organisms, and a more general one, which includes as well nonliving systems, possessing certain properties. Since I shall have to use both **meanings**, I have found useful, to avoid confusion, to introduce the term 'org' for the broader **meaning** of organism, and to reserve the full word for the biological subgroup" (1956, p.155).

GERARD did not use the word "organization", but proposed two other neologisms:

- "animorg", designating **living systems**, as opposed to non living ones;
- "epi-organism", designating **colonies** or social systems composed of **living systems**.

Later on, von FOERSTER proposed the term "**artorg**" to denominate organized artificial systems. None of these neologisms became really accepted... and it seems unfortunate, because they characterized important **distinctions**.

Moreover, the word "organization" gives also way to at least two different **meanings**:

- to designate the **set** of any systems' **structures and functions**;
- To designate a specific type of **human systems**, which numerous **elements** assembled in more or less well defined **structures**, according to the functional necessities of the system. (See for example A. RAPOPORT & W.J. HORVATH, 1959; M. HAIRE, 1959; G. VICKERS, 1957).

2427

ORGANIZATION (The nine levels of) according to J.L.E MOIGNE^{2) - 4)}

This classification responds to purposes different to MILLER's, but is in no way contradictory nor incompatible.

J.L.E MOIGNE (1977, p.97-112) describes the following nine **levels of modelization** of the organization of the "**objects**" (a term comparable to "system" for the more differentiated levels):

- The **passive object**: which, simply, exists and in most cases corresponds to a quite elemental level: an atom, a molecule, a crystal, a planet, a word.
- The **active object**: which takes part in some **activity**: the atom which gives cohesion to a molecule, the word which has a specific sense in a sentence.
- The **regulated object**: Which counts with an internal device selecting its future **behavior** in relation to its former one, by way of some **feedback** of the **output** on the **input**.
- The **informed object**: which possesses an internal device including a register of its previous **states** allowing in **association** with the **feedback** device, for conditional **behaviors**.
- The **object fitted with a decider**: which acquires a device allowing it possibilities of alternative **choices** in relation to the available **information**, "when the **action** of the system is an **event** for which occurrence no **change** in the **environment** is necessary, nor sufficient" (ACKOFF, 1971) or "when not being unavoidable, the **choice** of the **action** must be decided by the **object** itself" (LE MOIGNE, 1977, p.103).
- The **active object, endowed with memory**: i.e. fitted with a **repertory** of former **situations and actions**, which permits the definition of **decision criteria**. LE MOIGNE observes: "A **decider** without **memory** and whose **behavior** would not be aleatory, can only be an **algorithm**" (p.107). The **memory storage** implies the existence of a "memorization **processor**" which provides the internal **representation** of the **information**.
- The **coordinated active object**: which carries on multiple **decision processes** related to multiple operative **processes** and is fitted with a general arbitration **processor** which decides between the various necessities in charge of specialized **processors**. According to LE MOIGNE, the concept of **coordination** is better than the **integration** concept, as it "refers to a **function** that must be ensured, but not necessarily to an imperative project" (p.111).
- The **imaginating active object**: in which some **processors** are able to interpret **information** that, for others, is mere **noise**. In such conditions, new **connexions** may appear among **processors** within the system and modify its **behavior**. **Self-organizing** capabilities emerge, correlated to **learning behaviors** and **emergence** of intelligence.
- The **self-finalizing active object**: The **object** acquires "the ability to create its own projects: if it can be finalized it may also be finalizing" (p.115). LE MOIGNE thus quotes J. MELESE: "The finalities of a system cannot be understood, and still less be constructed if not in relation to its **connexions** with its surroundings... The system... may be charac-

terized as the **interface** between a finalizing will and an **environment**" (MELESE, 1972, p.53).

LE MOIGNE admits, however, that this "finalizing will" is still an imprecise concept" (p.115).

According to LE MOIGNE, the first four levels constitute the field of mechanics, while the last five pertain to **systemics**. LE MOIGNE's text is illustrated with figures that quite enlighten the nature of these nine levels of organization.

2428

ORGANIZATIONAL CLOSURE^{1) - 2)}

The concept of organizational closure does not mean that the system is **isolated**, nor even that it is **closed** or nearly closed.

No system can survive without **assimilation** of various **classes** of **inputs** flowing from its **environment: matter, energy, information**.

However, the system could not survive if these **inputs** should disorganize it and destroy its **cohesion** and **identity** (something which however happens frequently in the real world).

Organizational closure refers to the conservation of the systems basic **structures** and **processes**. This is obtained through its capacity, thanks to internal **operators activity** (corresponding to **operational closure**) to:

1°- transform its **inputs** to make them useful to its correct functioning (**assimilation**). It should be noted that "**inputs**" are not to be given the same **meaning** as in the **behaviorist** direct **deterministic** view of "the **stimulus** for a specific **response**".

2°- transform its internal **states** to compensate, if needed, any **disequilibrium** resulting of the absorption of foreign **elements** (**adaptation**).

These **transformations** may be **cyclical**, or **hypercyclical**, but the number of possible **states** is necessarily limited, while however it may be very high.

VARELA states: "It is as if once the closure of the system is achieved... it automatically takes care of the generation of its internal regularities" (1984, p.26). Or "... **inputs** become a **perturbation** or **noise** when they are no longer necessary to the systems' **organization**." (GO-NELLA, 1976, p.312).

On the other hand, **organization** should not be confused with **structure**: "(The system's) **organizations** are the necessary **relations** which define the system and its **structure**... are the actual **relations** between the **components** which integrate the system as such. Thus ex-definitione the **organization** is **invariant** while a system maintains its **identity** without disintegration; **structures** can vary provided they satisfy the organizational **constraints**" (VARELA, 1975, p.25).

And moreover... "From an **input** type stance, a system is adaptative because it is optimally **fitted** to a given world. From a closure type stance, a system is adaptative simply because *its organization is maintained invariant* through **changes of structure** which do not violate **constraints**" (p.27).

Such a state of affairs may however block necessary **adaptations** when the "given world" undergoes some basic **change**. Accordingly, G. BROEKSTRA states: "Organizational closure is essentially a **non-equilibrium** concept akin to **autocatalysis** and underlies the ordering principle of **order through fluctuation**" (1993, p.78).

One wonders if VARELA would have admit this extended interpretation, at least for biological systems.

2429

ORGANIZATIONAL CLOSURE: A Critical Study^{1) - 3)}

F. BONSACK evaluates critically F. VARELA's concept in the following terms:

"His system is as follows: There is, basically, a causal **net**, internal to the system; the **components** mostly interact: He speaks about "organizational closure". Of course, he makes clear that "closure" is not the equivalent of "closedness". However it is not less true that the first looks much like the latter and that the only noteworthy difference is that it accepts "**perturbations**" to which the internal **net** of **interrelations** reacts globally, reinstating **equilibrium**. What is generally called **information**, for example the sensations, are reduced in that way: there are not **inputs**, but only **perturbations**.

"And the **outputs**? One looks in vain for them: the system closes on itself, it does not act outward. VARELA gives at page 225 of his book "Principles of Biological Autonomy", a schema where a **net** of **interactions** may be seen: an arrow coming from outside but no arrow pointing outward. In his NEUCHATEL conference, he described at large an annular **cellular automata**, which he presents as a **model** of **autonomous** system. Again, arrows may be seen coming from outside, but none directed outward. He writes explicitly: "I say "closure" in the sense that any intersection of the system leads *not to a response towards the outside* (BONSACK's emphasis), but to a new **interaction** within the system itself". And farther on: "The consequences of the system's **operations** are system's **operations**". The system thus closes on itself.

"How to understand this curious stand?

"The most plausible hypothesis is that, for VARELA, the system's **activity** is centered on its own conservation, on a continuous **autopoiesis**, on the defense of its own integrity – which may be admitted.

"However VARELA seems to forget two aspects:

"The first one is that, according to his own theory, **autonomous** units may fuse to form an **autonomous** unit of superior **order**, for example a **group** of individuals, a society, a culture. And, in such a **frame**, the inferior units must necessarily produce an **output**, providing something to the other units, or performing some **function** within the **frame** of the superior unit. Contrarywise, no superior unit could exist, these would be only a collection of inferior units, all closed on themselves, without links or **interactions**.

"The second aspect that VARELA seems to forget, is that, among the retroactive causal chains which permits the **maintenance** of the individual's integrity, many do not remain internal, *but cross through the world*. Let us think for example to the search for food!

"This entails two consequences:

"Firstly: as the chain crosses outward, there is an **output** when it exits from the system and, at least, one **input** when it comes back.

"Secondly: if the chain is to be efficient, a **knowledge** of the world must exist, of the **objects** and the causal **relations** that are to be used. It is thus unavoidable, in one way or another, that the system be equipped with a world **representation** that will permit it to simulate the **objects behavior**. It is thus unavoidable for it to count with genuine **information inputs** (which are something different from **perturbations**) in order to be able to create that world **representation**. Yet, VARELA rejects not only any **input**, but altogether any world **representation**. He writes (I translate):

"In this perspective, what we call "**representation**" is not a correspondance with some kind of given **state of matter**, but better, a **coherence** with the continuous **maintenance** of its own **identity**. Such regularities ("behavioral regularities") which we choose to call "symbolic", are *not* operative for the system, because it is *us* who establish a correspondance from a viewpoint which is not within the **operation** of the system" (end quote).

.....

"One has the impression, reading VARELA, that he attaches a positive value to anything internal to the system, while all that is external is negatively valued: For example, **information** become a "**perturbation**". For him, the outside is the ennemy of the autonomous system" (BONSACK, 1990, p.110-112).

P. CARIANI, inspired by G. PASK, relates organizational closure with "the self-construction of the **observer**". He writes: "When a device gains the ability to construct its own **sensors**, or in Mc CULLOCH terms "this ability to make or select proper **filter** on its **inputs**", it becomes organizationally closed. The device then controls the **distinctions** it makes on its external **environment**, the **perceptual categories**

which it will use. On the **action** side, the device acquires the ability to construct its own **effectors**, and with them gains **control** over the kinds of **actions** it has available to influence the world. The self-construction of **sensors** and **effectors** thus leads to an **epistemic autonomy**, where the **organism** or device itself is the major determinant of the nature of its **relations** with the world at large... This basic concept of structural closure and its consequent, functional **autonomy**, underlies many of the closely related notions of *semantic closure* (PATTEE), *autopoiesis* (MATURANA, VARELA), self-modifying systems (CSANYI, KAMPIS), **self-reproducing automata** (von NEUMANN), **anticipatory** systems (ROSEN) and the recurrent "**nets with circles**" of Mc CULLOCH and PITTS" (1993, p.30).

In synthesis, organizational closure can, and must be *acquired*, even if on the base of a primeval biological level of closure.

Finally, CARIANI makes the following and very significant comment about programmed devices: "They fail to achieve **epistemic autonomy** relative to their designers because all possibilities have been prespecified by their designers" (p.30). This means that externally imposed **algorithms** preclude the formation of internal ones.

G. PASK clarified these aspects as early as 1958 and 1961(b). Possibly too early to be well understood!

2430

ORGANIZATIONAL DEPTH³⁾

"A system's organizational depth is measured by the degree of nesting of sub-ordering relations within its global ordering **relation**" (W.O. CHRISTENSEN & C.A. HOOKER, 2000, P. 136)

The best global examples of organizational depth can be found in J. MILLER's **taxonomy of living systems**, either **bottom up** from the **cell level** to the global supra-national system, or vice versa. Neither the down-level **subsystems** can survive if not integrated into a higher-level one, nor the higher-level system can maintain itself if it does not satisfactorily integrates its subsystem in a coherent manner.

Conversely, a crystal, while structurally organized, has no organizational depth, as its **parts** can generally be cleaved without being destroyed, not being functional in any way.

→ **Complex (Supremacy of the); Priority of the simple**

2431

ORGANIZATIONAL LEARNING^{2/4)}

K. BAUSCH describes organizational learning as follows: "A **process** of developing organizational capacity and human capability to articulate and continually examine the **purposes**, underlying perspectives and **assumptions**, and individual and organizational **values** in view of

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

- a) the **performance** of the **organization**
- b) the changing characteristics and expectations of the **environments** in which the organization is **embedded**" (Glossary, Pers. comm., 2002)

This is in fact the program of the "**Evolutionary Learning Community**" (ELC)

- The following aspects seem most important:
 - the nature and conditions of learning (general and specific) should be deeply researched
 - a thorough critical examination of all assumptions and values should be undertaken and periodically repeated in order to avoid **underconceptualization**
 - purposes should be examined in a similar fashion
 - the aim is not to find recipes, nor solutions. It is to create evolutive **design**
 - the designers should avoid **clanthink**, be aware of possible **blindspots**, escape from "politically correct" rules and develop **creativity**.
- **Design (Systemic approach to); Design (Generic); Design methodology (Systemic); Group technique (Nominal); Interpretive structural modelling; Organization**

2432

ORGANIZATIONS' DESIGN and OPERATION ⁴⁾

According to ACKOFF: "... one who wants either to create an effective organization or to improve the **operation** of an existing one... has four basic types of approach to organizational **effectiveness** and combinations thereof. The basic types of approach correspond to the four essential **characteristics of organizations**." (see here upon: "**Organization as a system**")

B. BANATHY differentiates the characteristics of old style or new style organizations (see 1993, p.248).

Older organizations tend to **dynamic stability** obtained through **hierarchical control**, a generally closed logic and the search for **efficiency** focused on **short-term goals**.

Newer organizations admit shared power, **cooperation**, **long-term** perspectives and **creativity**.

It should be observed however that, as organizations of the second type (in business, politics, science, etc...) tend towards **stabilization** and maturity, they also derive towards the first type.

2433

ORGANIZER ²⁾⁵⁾

Some biologists – among them H. SPEEMAN – discovered that the amphibian embryo contains a section that has the potential to induce and to promote-when grafted in another embryo- the

appearance of a second embryo, in many cases complete. This section has been called "organizer"

C. WADDINGTON described in detail this **process** of embryonic **determination** as a sequence of progressive **constraints** on the original **equipotentiality** condition (Waddington's inverted cones, as a diagrammatic way of representing this course of embryonic determination) (See J. NEEDHAM, 1968, p. 58)

The organizer is also a feature of WADDINGTON's **morphogenetic fields**. for his part, the Belgian biologist A. DALCQ tackled the organizer concept in his 1940 book.

Of course, a disquieting question mark remains: "How does the organizer appear?" , as for example in CSANYI's proposed **zero-system model**.

Another intriguing point is the possible existence of organizers as features of complex biological and of metabiological systems. On this point, NEEDHAM writes: "It was soon recognized that the organizer **phenomena** were not confined to amphibia, for parallel cases were found in echinoderms (HÖRSTADIUS) insects (SEIDEL), and birds and mammals (WADDINGTON) (p. 83)

And could the organizer model be translated to meta-biological and **social systems**?

→ **Autogenetic system precursor; Bifurcation; Gradient; Morphogenesis; Nodal activity; Positional value; Threshold; Zero-System**

2434

OSCILLATION ²⁾

A more or less **periodic change** of the values of a **function** in a system.

Oscillations can be: regularly sinusoidal; of relaxation; **periodic** but complex (i.e. composed of various sinusoidal oscillations of different **frequencies** and **amplitudes**); mixed **chaotic** and **periodic**, or totally **chaotic**. (I. PRIGOGINE, 1984, p.55)

In **dynamic equilibrium** conditions, they are generally steady or progressively **damped**. **Far- from- equilibrium**, they become amplifying **fluctuations** and finally lead the system over an **instability threshold**. This in turn is conducive either to its destruction or to its **emergence** at a higher **level of structural and functional complexity**.

The **homogeneous steady state** could be considered as non-oscillatory.

Oscillations can be an effect of **time lags**.

This has been demonstrated long ago by VOLTERRA and LOTKA's study of the **population's fluctuations**.

More recently, it is a characteristic feature of J. FORRESTER's **Systems Dynamics**.

This is quite understandable, as the corrective **action** of any **regulator** is *always late*: its impact is felt on the controlled **value** when other **variations** already changed the **value's level**.

P. MANZELLI states (with reference to biochemical **processes**): "...oscillating reactions show an **auto-organized action** that needs the supposition that the interacting particles can "communicate **information**" among themselves to establish a global **behavior** of the **space/time transformation** of the **reaction**" (1993, p.334).

This **process** results generally of intricate **sets of feedbacks**, as in **catalysis** or **hypercycles**.

2435

OSCILLATION (Reverberating) ^{2) - 4)}

An unendingly repetitive **transformation** from which the **process** or system is not anymore able to escape.

St. BEER writes: "... when this happens in the **brain**, the subject is called neurotic. Official politics, particularly in the field of economic affairs, seem to be given to such neuroses"(!) (1968, p.477).

A system captured into this kind of rut is in great danger, because it has lost its **adaptive-ness**, frequently in an irreversible way.

2436

OSCILLATION (Self-) ²⁾

An oscillation that appears spontaneously in a system.

This curious phenomenon has been first researched by POINCARÉ. S. DINER describes as follows its characteristics:

- "**amplitude** and **frequency** independent of **initial conditions**;
- "**emergence** independent of any external **periodic** stimulation;
- "**control**, through **feedback**, upon the **energy source**, in order to compensate **dissipation** without influencing **amplitude** and **frequency**".

DINER defines an auto-oscillator as : "A system generating non-**damped** oscillations, sustained by an external **energy source**, in a **non-linear dissipative** way, and whose aspect and properties are determined by the system itself, without **dependence** from its **initial conditions**. In such conditions, oscillations can be not merely **periodic**, but also **quasi-periodic** and even stochastic. ANDRONOV (in 1929)... showed for the first time the physical existence of an **attractor** that was not an **equilibrium point**. Later the concept of **attractor** was to be amplified up to the emergence of the **strange attractor** concept, the mathematical form of stochastic self-oscillations" (1992, p.340-1).

This could be considered a kind of **thermo-dynamic autopoiesis**!

2437

OSCILLATIONS (Shortening) ²⁾ - ⁴⁾

W.D. GROSSMANN and K.E.F. WATT stress that "there is an increase in **amplitude** and decrease in wavelength of all major **wave-like oscillations** in society... This gradual decrease in wavelength is striking in **graphs** plotting year by year, from 1740 to the present, the wholesale price index adjusted for its long-run **trajectory value**".

This implies a rapid "decrease of **time-spans** for **reactions**" with the aggravating factor that economic and political leaders are generally unaware of this **situation**.

The authors give other examples and evaluate this **phenomenon** as of "Severity rating 1" (1992, p.35).

This **phenomenon** is closely related to **evolutive acceleration** and both seem to indicate the progressive **dominance** of **chaotic behavior** in **human systems**, highly probably in relation to the exponential **growth** of **energy** use.

2438

OSCILLATOR ²⁾

"Any system that executes **periodic behavior**" (S.H. STROGATZ and I. STEWART, 1993, p.68).

These authors give the most simple and classical example, the pendulum and comment that "... it returns to the same point in **space** at regular intervals; furthermore, its velocity also rises and falls with (clockwork) regularity". They add: "A simple pendulum consisting of a weight at the end of a string can take any of an infinite number or closed **paths** through **phase space**, depending on the height from which it is released".

This corresponds to the **linear** or harmonic oscillator mathematical **model**, related to **FOURIER analysis of periodic functions**.

Moreover: "Biological systems (and clock pendulums), in contrast, tend to have not only a characteristic **period** but also a characteristic **amplitude**. They trace a particular **path** through **phase space**, and if some **perturbation** jolts them out of their accustomed **rhythm** they soon return to their former **path**" (Ibid).

However, an oscillator with many interfering **frequencies** not in **harmonic** relations behaves – or seems to behave – **randomly**. This is the case of the forced oscillator, in which the introduction of a **perturbation** disturbs the regular **periodic behavior** and induces it in a partly, or totally **aperiodic**, or **chaotic** movement.

In complex systems with a supposedly **deterministic behavior**, such a **perturbation** normally leads to a greater **unpredictability**.

S. STROGATZ and colleagues have shown and mathematically proven that collection of oscillators, whose **frequency** can respond to those around it, will end up in **synchrony**.

This is a deep and very general discovery which establishes a basic **model** for the spontaneous **emergence** of **order**, out of apparent disorder.

The first observation of synchronization was made by the Dutch physicist Chr. HUYGHENS (1629-1695), between two clocks

→ **Belousov Zhabotinsky reaction**; **Order**; **Network**; **Smallworld**; **Synchronicity**

2439

OSCILLATOR (Limit cycle) ²⁾

"An oscillator that has a standard **wave-form** and **amplitude** to which it returns after small **perturbations**" (S. STROGATZ and I. STEWART, 1993, p.68).

The authors explain how such oscillators work: "They incorporate a **dissipative** mechanism to **damp oscillations** that grow too large and a **source** of **energy** to pump up those that become too small" (Ibid).

In the case of **living systems**, the result is **homeostasis**, acquired through suitable **regulations** and the use of stored **resources**. P. VENDRYES' counter-aleatory **reserves** concept is closely related.

2440

OSCILLATORS ²⁾

The theory of oscillating **processes** and systems has been developed in successive steps, its **models** progressively nearing the concrete **situations**.

The simplest oscillator shows a regular and invariable **periodic behavior**. It does not take into account the degradation of **energy** which results, for example, of frictions. This type of oscillators is neither **time-dependent** nor **environment-dependent** and can be described by any **function** characteristic of **non-dissipative processes**. It has no **attractor**.

However, such a **model** is totally abstract and theoretical, in close **relation** to the concept of **isolated system**, in use in **classical thermodynamics**.

Conversely the next **model** of oscillator considers the **irreversible dissipation** of **energy** and **growth** of **entropy**. In this case, more realistic, the system's **trajectory** tends to a final point of **static stability**, i.e. a point of **attraction**, or simply, an **attractor**.

This is the case, for example of a pendulum that receives no supplementary **energy** from its **environment** and is thus not able to compensate for the monotonous loss of usable potential. The **behavior** of this class of oscillators is defined by a positive and monotonously decreasing **LYAPOUNOV's function**, corresponding to the progressive **damping** of the **amplitude** of their movements.

There are however numerous systems which cannot be represented by such a **model**: those which receive from their **environment** an **energy** supply equal or superior to the **energy** that they are able to dissipate. In the first of these cases, the system heightens its **entropy** production up to a **level** at which it becomes able to maintain its **dynamic stability** for a long time. (**Equilibrium thermodynamics**). This case corresponds to the emergence of a **stable limit cycle** characterized by a **VAN DER POL's attractor**.

If the **energy input** becomes superior to the **dissipation** capacity of the system, it will undergo uncontrollable growing **fluctuations**, eventually cross a **threshold**, become unstable and pass through **bifurcation** points corresponding to deep alterations. This may lead to **chaotic behavior** and the future of the oscillating system becomes unpredictable.

2441

OSCILLATORS (Coupled) ²⁾

Oscillators that influence one another and become synchronized.

This intriguing property was discovered by Chr. HUYGHENS in 1665.

S.H. STROGATZ and I. STEWART state: "Coupled oscillators can be found throughout the natural world, but they are especially conspicuous in living things: pacemaker **cells** in the heart, insulin-secreting **cells** in the pancreas; and neural **networks** in the **brain** and spinal cord that control such rhythmic **behaviors** as breathing, running and chewing. Indeed, not all the oscillators need be confined in the same **organism**: consider crickets that chirp in unison and congregations of synchronously flashing fireflies" (1993, p.68).

A mathematical theory of coupled oscillators has been developed and new angles have appeared recently through the **chaos theory**. The subject is obviously related to the composition of oscillations of different **periods**, but the way through which the significant "**information**" passes from one system to another is still in many cases not clearly understood.

Coupled oscillators must also have some relation with HAKEN's **slaving principle** and are an obvious necessity in organized systems and even in more or less synchronized **quasi-systems**, as for instance fish **swarms** (see D. RITZ, 1991).

2442

OSCILLATORS (Systems of) ²⁾

Transitions between some uncoordinated **state** of numerous **elements** and their grouping as a **composite system**, or even an **integrated** one may be interpreted as the **coupling** of numerous **oscillators**, which **behavior** becomes **phase locked**.

This can be exemplified by amoeba, fish, or fireflies, or locusts **swarms**, and probably in the dynamic groupings of **neurons** in the brain. The condition for such a **transition** is the existence and sufficient power of a **communication mode**, which can be biochemical, or electric, visual or auditive.

2443

OSCILLON²⁾

A very simple oscillating **pattern** obtained by vibrating a thin layer of sand grains.

The oscillon was discovered by Paul UMBAN-BOWAR, Francisco MELO and Harry SWINNEY (Univ. of Texas at Austin).

It seems to be the very fundamental **self-organizing pattern** obtained by **energy dissipation** and leading to **structuration**.

Oscillons, according to SWEENEY, "can join together to form chains, triangular associations and even extended **lattices** - and all are stable". (as quoted by Marcus CHOWN, 1997).

CHOWN adds: "The square **lattice** (would be) simply the lowest-**energy configuration** of an even mix of attracting and repelling particles... (as in) an antiferromagnetic **lattice** (in which) each positively charged particle is surrounded by four negatively charged particles in a square **lattice**" and, ... "By contrast, the lowest **energy configuration** of like-charged objects is a **hexagonal lattice**". (p.37)

→ Hexagonal space filling; Order parameter; Soliton; Structure (Dissipative); Symmetry (Hexagonal); Vortex

ÖSTERREICHISCHE STUDIENGESellschaft für KYBERNETIK

→ Austrian Society for Cybernetic Studies

2445

UGHTNESS: Two complementary systemic meanings^{3) - 4)}

There are two different identifiable **meanings** in systemic terms to the **concept** of "oughtness" as introduced by A. BAHM (1978 - 1992).

The **regulation** of road traffic offers a good example. First, traffic ought to be organized through **rules** in order to make it efficient as a transportation system. This includes priority **rules**, overtaking **rules**, maxima and minima speed limits, a **code** of traffic lights and other road **signals**, etc... This "oughtness" is related to a sound **organization** and **regulation** of a very complex **man-machine system**, needed in order to avoid collective anarchy, leading to total paralysis.

Second, these **rules** and **regulations** would be totally ineffective if not obeyed by the human users. This is the "man" part of the **man-machine system** and it implies a sense of personal responsibility in every user.

The traffic **code** must not only be understood as a **set** of integrated **rules**, but also as a system organized for the best welfare of all users, which *ought* to be *respected* for the sake of social harmony. As some users are not understanding this necessity, society as a **whole** created a special social corps - traffic patrols - to attend this non-technical aspect of the traffic system.

Curiously, this last feature introduces *two* quite different ways to understand oughtness: either through one's sense of responsibility, or through the fear of penalties.

These different technical and social ways to understand what could be called techno-social **situations** are at the root of the differences opposing some systemists' point of views, as for example H.A. SIMON and C.W. CHURCHMAN.

→ Systems Philosophy

2446

OUTBREEDING¹⁾³⁾⁴⁾

In a strongly worded critique of social sciences **methodology**, M. MARUYAMA signals one of the most unsatisfactory characteristics of much contemporary specialized disciplines, which is "inbreeding", i.e. the wide ignorance of anything that lies (or seems to lie) outside of the rigidly established limits of their discipline. This leads unavoidably to "**tunnel vision**" and conceptual isolation (1998, p. 91-108)

Obviously he proposes "outbreeding" i.e. the crossing of disciplinary boundaries, as a convenient cure.

MARUYAMA himself "outbred" not only scientifically, but also culturally, during many years, having lived in various European and American countries and, of course, Japan.

Outbreeding of any type triggers a **process** of questioning one own's **concepts** and **frames of references**, which are in many cases unable to contain different ways of **understanding**...and even of **perception**.

If one freely accepts outbreeding, one's original mental and psychical **frames** come under **stress**, sometimes even severe. However, at the same time, **adaptiveness** increases and wider and richer frames of references can be constructed.

It is surely not coincidental that many-maybe most- of the outstanding founding fathers of cybernetics and systems thinking have been expatriates.

2447

OUTLET²⁾

A place in the **boundary** of a system or **sub-system** through which it emits some specific type of **outputs**.

Outlets generally have a closing/opening device which **control** the **outputs** in **time**.

In Spanish, there is a frequent confusion, probably due to incorrect use of accounting vocabulary, between the outlet and the **output**, both named "salida". This term has been now restricted to the **meaning** of outlet, while "**output**" is presently translated as "egreso".

The same problem has been solved in French through the introduction of "intran" (for **input**, in lieu of "entrée") and "extrant" (for **output**, in lieu of "sortie") (R. VALLÉE). However, these terms are not yet of general use.

2448

OUTPUT^{1) - 2)}

"Whatever the system produces and sends back into its **environment**" (B. BANATHY, 1988, p.87).

Outputs can be of **matter**, **energy** or **information**.

Matter emitted has generally been transformed, either upgraded or downgraded. **Energy** is normally downgraded by the system, which uses it to activate its internal **processes**. **Information** is mostly upgraded or even directly created within the system.

Any output has a destination into the **environment** whether fuzzy or precise.

The **whole** or **parts** of the **environment** act as **sinks** for the system outputs. It is very important to know to which extent the **environment** is able to accommodate itself as a **sink**, for, once crossed a **critical threshold**, the system may well suffocate in its own products, be it pollutants, over- production of some item, or over-**population**, for example. This implies the need to study the **rate** of production of every significant output, in order to be able to define **optima** and bearable maxima.

It should be noted that many systems produce some types of outputs while being unaware of it, bringing about some unsuspected **side-effects**, as for a recent example, the ozone hole produced by chlorinated propellants.

Outputs must cross **boundaries** or **interfaces**. The way they do it in **space** and **time** is also a very important feature of the **interrelation** between the system and its **environment**.

Finally, the previous convenient conditioning of the output within the system is of utmost importance in relation to the acceptance by the **environment** and the **reactions** of the latter towards the system.

2449

OUTPUT BOUNDARY²⁾

Any system **function** which relates some system **variable** to **environmental variables**.

This definition equates any boundary with a specific class of **functions** which relates the system with its **environment**. While boundaries are indeed functional (as well as **structural**) one wonders if, for example, internal **organs** in

living systems as, let us say, the digestive tract, should be considered as parts of the boundary and, if so, where to place the **limits** of the system.

2450

OUTPUT PROCESSING²⁾

"The **operations** that identify and assess systems-relevant output and introduce that output into the **environment**" (B. BANATHY, 1973, p.87).

These **operations** correspond to the **activity** of J. MILLER's output **transducers** of **energy**, **matter** and **information**.

2451

OUTPUT TRANSDUCER²⁾

"The **subsystem** which puts out **markers** bearing **information** from the system, changing **markers** within the system into other **matter-energy forms** which can be transmitted over **channels** in the system's **environment**".

This is one of J. MILLER'S **20 critical subsystems in living systems** (1978, p.3). Together with the **ingestor**, the **input transducer** and the **extruder**, it is one of the **subsystems** which communicate the system with its **environment**.

2452

OVERBURDENING^{1) - 2)}

The imposition of an excessive exigence or work on a system.

This notion is closely related to the **overload** one. It corresponds to the often cited proverb about "the last straw that broke the camel's back". However, in many cases, the **operator**, **decider** or manager remains unaware that he is operating close to an **instability threshold**... or crossing it, and the back of the camel breaks.

One of the main causes of such an unawareness is the lack of **perception** and **understanding** of slow **accumulation** of small **effects** in systems at long or very **long term**. This **situation** is particularly dangerous in our time, when all **processes** are becoming interconnected and are accelerating.

2453

OVERCROWDING^{1) - 2) - 4)}

The gathering of an excessive number of **elements** in a limited **environment**.

When **elements** of a system begin to increase considerably in an **environment** that cannot be expanded, they exert growing reciprocal **constraints** on their displacements and, more generally on their **activity**.

This **systemic pathology**, which amounts to a kind of **environmental poisoning**, has been diversely described by, for instance:

- the French sociologist R. BOUDON, who coined the expression of "perverse **effects**";
 - J. CALHOUN in his research on **population density** and social pathology (1962 and 1971);
 - R. ARNOTT and K. SMALL in their study on the economics of traffic congestion (1994).
- The subject is ominously important for any species in full demographic explosion... as ours is.

2454

OVERLOAD²⁾

Excessive **density** of pulses in a **channel** or **set of communication channels**.

Such a **situation** appears when an excessive number of **transmitters** and **receptors** have an access to the **net** and that there is no **control** device to restrict the possibilities to emit or receive **messages** in accordance with the maximal (global or local) capacity of the **net**.

Any overload leads to the disruption of **parts** of, or the whole **net**, frequently through **chain reactions**, (also typical of **composite systems**), which may well be **irreversible**.

The concept can be extended to any **class of nets** (electrical, informative, neural, social, etc...).

2455

OVERLOAD (Information input)^{2) - 4)}

A cross-level study on this subject was published in 1960 by J. MILLER, who extracted from it an "Information input overload" concept that he states as follow:

"As the information input to a single **channel** of a **living system** - measured in **bits per second** - increases, the information **output** - measured similarly - increases almost identically at first but gradually falls behind as it approaches a certain **output rate**, the **channel capacity**, which cannot be exceeded in the **channel**. The **output** then levels off at that **rate**, and finally, as the information input **rate** continues to go up, the **output** decreases gradually toward zero as **breakdown** or the confusional **state** occurs under overload" (1986, p.77).

Experiences were pursued at five different levels: the **cell**, **organ**, **organism**, **group** and **organization**. As a result: "Data from the five biological and social **levels** yielded information **input-output** curves, the similar shape of which - a cross-level formal **identity** - confirmed the hypothesis." (ibid).

→ **Christmas tree effect; Information overload**

2456

OVERSHOOTING^{1) - 2)}

A **process** which tends to send the system outside of its **dynamic stability limits**.

Overshooting is generally a result of **time lags** in the system's **responses**. It may destroy the system if not controlled in due time. Moreover this **control** is difficult and, in some cases downright counter-intuitive.

This **process** has been very well described in J. FORRESTER's **Systems dynamics**.

The subject is of utmost importance for **governance** in pursuit of a sustainable **management of human systems**.

2457

OVERSIGHT¹⁾³⁾

An unintentional and generally inadvertent omission or mistake

M. MULEJ observes that the **reduccionist** view of issues leads frequently to a **variety** of intricate and unexpected consequences, that may introduce new **issues**, many times difficult by themselves (1991, p.316-17).

Only by applying good criteria to determine the **interdependence** of **causes**, conditions and consequences can oversights be avoided.

MULEJ also underlines the necessity to guard oneself against superficial use of pseudo-system thinking, as for example:

- mastering fictitious **wholes**, but no factual **wholes**
- thinking "**holistic**", but behaving and acting "fragmented"
- use simple-sided ("**tunnel vision**") or merely dialectical **understanding** and enclose oneself unwittingly into such views
- dividing conceptual labor instead of **net-working**

According to MULEJ, problems at the planetary level, for instance, are objects of "Conferences... arranged by the United Nations and make good conclusions, but **actions** are blocked by single-sided, tunnel vision kinds of interests" (p.326)

In conclusion, MULEJ proposes an "ethics of **interdependence**"

2458

OVERSTOCKING^{1) - 2)}

The existence of a number of **elements** or users of a system such as the **resources** of the same become strained and eventually used up.

Overstocking is a frequent **systemic pathology**. It is one of the characteristic forms of **environmental abuse** described for instance in G. HARDIN's "**Tragedy of Commons**".

Overstocking is an insidious **phenomenon**, that people remain unaware of, until very dangerous **thresholds** are approached... or crossed. Many **processes** of this type are currently on the march in **ecosystems**, **economics**, uses of natural **resources**, etc...

P

2459

P.E.R.T. (Program evaluation and review techniques)⁵⁾

An **array** of **systems analysis** techniques used to order, monitor and control projects, using **network analysis**.

An example is the **critical path method** for determination of the optimal chronological sequential ordering of tasks, or when needed, the definition of acceptable alternatives.

2460

PANACEA²⁾⁴⁾

"A simple-and simple minded-**solution** for a problem" (adapted from R.L. ACKOFF, 2001, p. 9)

So-called "recipes", "**magic bullets**" or "quick fixes" are all panaceas.

Good examples of panaceas are:

- Political slogans and unsubstantial generalities about "problems" in **education**, public health, security, **development**, etc., without any serious study of the obstacles, and of practical means to overcome them without creating **side effects**.
- Theories about **management**- as for example "re-engineering", "outsourcing", "downsizing", "organizational learning"- that could be useful only if applied thoughtfully to really well-understood and significant **issues** and specific cases.

Generally much simplifying and out of **context** panaceas are of scant value for addressing practical cases. They could be useful only if applied in an adaptive and readaptive way to a well studied issue or **situation** and with the well organized help from all the **stakeholders**.

Even so, there is an absolute need for a cyclically reiterative consideration of results and **revalidation** of our general **model** as a good **representation** of the issue and of our own **understanding** about what we are trying to achieve, and in which way.

On the contrary "panaceas are about doing things right, not doing the right things" (Ibid, p. 9)

In fact, the "panacea" problem cannot be avoided until we make ourselves able to distinguish what are the "right things" to do. WARFIELD's **generic design methodology** offers practical ways for avoiding **underconceptualization** and misunderstanding (brought about for ex. by **clanthink**, **groupthink**, **blindspots**, etc.) LINSTONE and MITROFF's "**unbounded systems thinking**" is also very useful, as well as CHECKLAND's **soft systems methodology** and the **critical systems thinking** offered by JACKSON, FLOOD and their Hull and Humber-side colleagues.

In short, a naive **belief** in panaceas results from a lack of critical understanding, mainly of one's own implicit illusions. Ackoff's final comment is that the market for panaceas "the weak sisters of fundamentalism" is still very large" (Ibid)

2461

PANDEMIC¹⁾⁴⁾⁵⁾

A worldwide **epidemic process**. This kind of processes is unfrequent, even at a historical scale, and luckily so because they are frightfully destructive. Historical examples are the "Black death" plague (1347-52), the rinderpest in East Africa (in the 1890's) and the so-called "spanish influenza" (1918-19)

Some religious conflicts (in Europe during the 17th century, or ideological **propagation** processes (fascism and communism in the 20th century) seem also to have been of pandemic extension.

2462

PANORAMA OF UNDERSTANDING¹⁾²⁾

H.. BENKING proposes a three-fold space-time panorama of understanding linking subjects, **objects** and **contexts**. He writes "The objective is to transcend and transform by thinking within, between and beyond, not inside "boxes" or domains"

Graphically, Benking proposes a representation through interconnexions between three boxes: the subject-box, the object-box and the context-box.

He writes: "The subject-box and the context-box are looking at the objects in the object-box, and the context-box enables us to map the **metaphors** of understanding the kind of reality in which this is taking place"

Each "box" is represented by a cube, that can easily be subdivided in more elemental sub-boxes corresponding to more specific **situations**.

This model is based, according to BENKING "on the **ekistic** grid, as conceived by DOXIADIS in the field of planning sciences. We can search not only for words, but for "areas" or "bodies" of **data** and **knowledge**. After agreement on **location** and content, genuine capabilities of man can come into play, which allow fast visual access and assimilation of very large volumes of data"

2463

PANORAMA THINKING¹⁾²⁾

H. BENKING considers that "We have to be able to talk about the same things with words which are grounded... We need to see terms and **concepts** in their **context**" ...

and "We can construct **frames-of-reference** as a **schemata** to visually reference and share diverse but inter-connected positions, focuses, ranges and horizons, in order to develop not

only common grounds but a tolerance for alternate ways of seeing our different **levels** and **scopes**"

By adequate and open **conversation**, we can create a common ground. In this way every player can discover his own place in the general panorama and understand better what he does and what he could and should do, or not do.

Benking advocates the construction of a good representation of the panorama (**Eco-cube/know map**)

We can use the cybernetic **tools** to order our **data-base**. But he warns that we should not let us stray in a "virtual **cyberspace**" in a mainly and merely technical sense, with no **relevance** to real **situations**.

Scales and proportions and their consequences should be duly taken into account in our representation, as we construct a 3 dimensional space/time **model**.

→ **Multiperspectivism**

2464

PARADIGM³⁾

A **meaning** system delineating relevance and nature of **data**, increments of measure, **criteria** of proof and **inference rules** (W. ACAR, 1988, p.121).

E. SCHWARZ goes even farther and defines it as "The **set** of the traits characterizing an **interaction mode** with the world" (1993, p.10). For him a paradigm also defines ways of **perception** and is closely related to culture. From an **epistemological** perspective it would be a "**semantic attractor**", acting as a **constraint** and, at the same time, as a stimulating factor. Finally, the paradigm also influences the way tools are made and used. An example could be the opposition between hypertechnical medicine and so-called natural-**holistic** one.

A paradigm thus becomes the reflection of a **Weltanschauung** (**world view**) and the invisible **pattern** that guides the construction of **theories**, **methodologies**... and even beliefs, justified or not by reasoning.

ACAR cites and discuss the different **meanings** given to the term by T. KUHN:

"... in much of the book the term "paradigm" is used in two different senses. On the one hand, it stands for the entire constellation of beliefs, **values**, techniques, and so on, shared by the members of a given **community**. On the other, it denotes one sort of **element** in that constellation, the concrete puzzle-solutions which, emphasized as **models** or examples, can replace explicit **rules** as a basis for the solution of the remaining puzzles of normal science" (1970, p.175).

Writes ACAR: "The first is, according to KUHN, an overall *sociological* sense, while the second is a more *technical* one which corresponds to the traditions and **criteria** that, in every **domain** of **inquiry**, distinguish "normal" from "heretical" science as well as define traditional disciplinary **boundaries**" (p.121).

ACAR cites P. SHRIVASTAVA and I. MITROFF, who write: "Paradigm guide the conduct of **inquiry** by defining legitimate research questions in a field, describing appropriate **methods** for addressing these questions, outlining the broad scope of an **inquiry** and encapsulating a researcher's assumptions in **inquiry**" (1984, p.18).

According to G.J. DALENOORT a paradigm "implies a set of beliefs, starting positions, **methodology**, and an **epistemology**, all concerning the **knowledge** making up a scientific discipline, that determine how one ought to interpret the **facts** of that discipline. Paradigm may even differ in their position as to what are the **facts**, and what the interpretations" (1989, p.1).

Science as it is made – under the **control** of some scientific establishment – is practically limited and in some cases repressed in the sense of KUHN or ACAR. But as many aspects of paradigms are **consensual**, they are intrinsically transient. However, the bedrock **rules** of **scientific method** constitute a quite immutable fundamental paradigm whose prescriptions cannot be ignored.

As to the system concept, it is possibly a new paradigm, but *it does not replace* the so called **reductionist** paradigm, *it merely complements* it, or reframes it.

D. BOHM and F. D. PEAT state: "Paradigms include not only systems of theories, principles, and doctrines, but also what we have called the "tacit infrastructure of ideas", which are transmitted to later generations of scientists in a kind of apprenticeship" (1987, p.26).

A paradigm presents thus a conscious proposal, but also a **set** of unconscious **constraints** on thought, which is the reason why, in the long run, it finally blocks **creativity** (i.e., when the productivity **limits** of the paradigm have been attained).

According to E. GUBA (1990), any paradigm can be characterized by three complementary **criteria**.

The first one is **ontologic**: it implies a basic stand about the correspondence with the postulated reality of the **knowledge** that can be acquired.

The second one is **epistemologic** and states the nature of the relation between **knowledge** and the knower.

The third one is **methodological** and defines the ways considered correct to further research.

None of these **criteria** can ever be definitively confirmed in any absolute sense. This explains why former paradigms are abandoned and new ones adopted.

J.van GIGCH examines in the following terms the justifications for the existence and uses of a paradigm: "A discipline, as well as the theory(ies) which constitutes a discipline need a paradigm for the following reasons:

1. A paradigm constitutes the "essence" of the discipline.
2. A paradigm constitutes the "world view" of its adherents.
3. Scientists in the discipline use the statement of the paradigm to establish the problems which it has to solve (KUHN, 1970).
4. The scientific establishment works usually in the direction of the prevailing paradigm, i.e., its **rules** and procedures are directed by the currently accepted paradigm (KUHN, 1970).
5. The paradigm is directly implicated in the **design** of the instruments, apparatus and **methodologies** used to solve the problems of the discipline (KUHN, 1970).
6. A paradigm is essential to discover (a) "anomalies" (KUHN, 1970) and (b) "dilemmas" (van GIGCH, 1993, p.42).

The same author, with J.L.LE MOIGNE, (1989, p.132) proceeds by examining the questions which a paradigm must answer and enumerates the following:

- "1. What are the main sources of knowledge of the discipline?
2. What constitutes the object of study of the discipline?
3. What are the main schools of thought underlying the discipline?
4. What are the main purposes of the discipline?
5. What are the significant instrumentalities (methodologies) used by the discipline and, by derivation, its main activities?
6. What are the anomalies and unresolved problems which are facing the discipline?

"Paradigms influence the **epistemology** of the **inquiring systems** over which they dominate and, in turn, the view of reality which emanates from these systems. Paradigms can be compared on the basis of the following headings:

- a) Description of the field,
- b) Nature of the **domain**,
- c) Problems to which suited,
- d) Applications of the paradigm,
- e) Nature of the solution (or of the "truth" obtained),
- f) **Criteria** used to evaluate "truth", and
- g) Proof and guarantor of "truth"

Finally, van GIGCH concludes: "We distinguish a paradigm from a **methodology** by indication that the paradigm is usually "content" or "substance-free", in the sense that it applies to many problems in the **domain** regardless of

their specific **content**, whereas a **methodology** is a problem-oriented procedure or approach which incorporates a particular paradigm" (Ibid., p.43-44).

This is why G. KLIR refers himself to *methodological paradigms*, based on "a particular **set** of assumptions, upon which different **methods** may be based... Each assumption contained in a methodological paradigm restricts the applicability of the associated **methods** and, consequently, restricts the **set** of possible solutions in some specific way" (1993, p.40). This explains, for instance, the frequently postulated *exclusive* complementarity between the **reductionist** and the **holistic**-systemic paradigms.

It should be noted that, before KUHN's book, "paradigm" had merely the meaning of "example". On the contrary, in the recent years, it has been uncorrectly popularized and used in many abusive ways.

For an interesting general evaluation of the impact of KUHN's work between 1962 and 1990, see J. HORGAN (1991).

E. MORIN observes: "A paradigm is unconscious, but irrigates conscious thinking and controls it". It can also thus be said that it is "supraconscious" (1999b, p. 26)

The dominant paradigm in a society determines a characteristic cultural **imprinting** (p. 27). The paradigm makes some aspects quite visible, but obscures or suppresses others.

2465

PARADIGM (Cartesian) ¹⁾³⁾

E. MORIN describes as follows the main characteristics of the paradigm derived from R. DESCARTES (1596-1650) philosophy and which dominated western thought from the 17th Century on.

"The Cartesian paradigm separates the "subject" from the "object", with a proper sphere for each: philosophy and reflexive investigation on one side; science and objective research on the other side" (1996, p. 26); **dichotomy**, and it emphasizes also the origin of growing and finally extreme specialization.

MORIN enumerates the following paradigmatic dichotomies in DESCARTES' worldview: "**subject/object**; soul/body ; spirit/matter; quality/quantity; **causality/ finality**; feeling/reason; **freedom/determinism**; existence/essence" (Ibid.).

2466

PARADIGM (Social) ¹⁾³⁾⁴⁾

A constellation of concepts, values, perceptions and practices shared by a community, which forms a particular vision of reality that is the basis of the way the community organizes itself (F. CAPRA, 1977, p. 6)

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Capra observes: "...twenty five years after KUHN's analysis, we recognize the paradigm shift in physics as an integral part of a much larger cultural transformation.

The intellectual crisis of the quantum physicists in the 1920's is mirrored today by a similar, but much broader cultural crisis" (p. 5).

According to Capra it is the mechanistic paradigm which is receding. This is obviously true. But this mechanicism had deeper and older roots in Western societies and is probably based on the paternalist and authoritarian God-driven worldview which still rules partially in Mediterranean societies.

Cultural anthropology and colonial dominance in the rest of the world slowly eroded this traditional cultural type through trans-cultural feedbacks. Moreover, while cybernetics is still in a sense mechanistic, organismic biology and its offspring, BERTALANFFY's original systems theory, as well as Gestalt psychology and more recently autopoiesis derived from von FÖRSTER 2nd order cybernetics are also prime movers of the paradigmatic shift.

In any case, no society can maintain its coherence and general activity without some basic social paradigm. In most of the cases this paradigm is basically expressed by some fundamental religious belief. During the 19th and 20th centuries some political or social ideologies tended to replace religious faith as social regulators. These substitutes have generally been short-sighted and short-lived.

→ **Autopoiesis; Non-no; Non-aristotelician thinking; Non-identity principle; Non-identity; Non-principles; Semantics (general); Synechism**

2467

PARADOX³⁾

A self-contradictory statement or argument.

The sorting out of paradoxes – which reflect a logical and semantic pathology – has been one of the roots of von FÖRSTER, MATURANA and VARELA's **cybernetics of 2nd order**. It had formerly led to RUSSELL and WHITEHEAD's critique of the fundamentals of logic and to BATESON's study of double-bind pathological situations.

Systemic models and concepts owe much to the study of the paradoxes pathology, as there was a basic need for a correct ordering of complexity levels in systems.

2468

PARALLEL DISTRIBUTED PROCESSING (PDP)^{1) - 4) - 5)}

PDP are softwares for use in parallel computers. They emulate neural networks in the brain and are used to "train" nets in these computers to construct representations of specific situations

RUMELHART enumerates the major aspects of a parallel distributed processing model as follows:

- a set of processing units ("neurons")
- a state of activation y_i for every unit, that determines the output of the unit
- connections between the units. Each connection is defined by a weight w_{ij} , which determines the effect of the signal of unit i on unit j
- a propagation rule (a governing equation), which determines the effective input u_i of a unit from its external inputs
- an activation function F which determines the new level of activation based on the effective output $u_i(t)$ and the current state $y_i(t)$
- an external input or offset θ_i for each unit
- a method for information gathering
- an environment within which the system must operate, providing input signals and – if necessary – error signals

(J. Mc CLELLAND & D. RUMELHART: "Parallel Distributed Processing Explorations in the Microstructure of Cognition" 1986).

This is the basic connectionist interpretation of the brain as the massively parallel computer, which depends on the general and local architecture of the connections between elements and on the dynamics of synaptic weights adjustments.

R. FISCHER explains PDP, applied both to artificial and natural intelligence, as follows: "In this... parallel distributed processing approach, learning takes place through changes in the system itself" (1992, p.208).

This comment seems to establish limits to the organizational closure concept: Before closure, organization must be constructed (but probably on the base of organizational closure already acquired at a lesser level of complexity, biological at least).

FISCHER adds: "The principle of PDP implies that activities of ordered sets of nerve cells can be considered to be mathematical vectors. An important aspect of this vector approach is that it focuses on the explanation of brain functions in terms of neural networks, i.e. mass action and that it is, therefore, compatible with the modular organization of the brain... The complexity of the neural circuitry of the cerebral cortex can be looked upon as a neural correlate of intelligence" (p.221).

FISCHER even observes: "At the interface of human mind functions and A.I. lurks the thought that the mind is trying to create intelligent systems in its own image" (p.226).

M. BODEN applied the PDP models to the activity of a group of children: "The class-decision is due to the parallel processing (all the children chatter simultaneously) of localized computation (each child speaks to, and is di-

rectly influenced by, only her immediate neighbours) and is distributed across the whole community (as an internally consistent set of mini-decisions made by all the children).

In PDP models, concepts are represented as activity-patterns across a group of units (Children)" (1990, p.121).

2469

PARALLELISM¹⁾²⁾

The simultaneous transformations of many relationships among many elements within a system.

Such a situation implies the existence of a significant number of coexisting processes and, as a consequence a certain leeway in the behavior of the system as a whole. It is however important to understand that the very concept of system implies also a global general – but not absolutely constraining – coherence.

Parallelism is altogether the condition for adaptive variation because it reflects a relative autonomy in space and time of different local behavioral lines in the system.

J. HOLLAND defines parallelism as the "concurrent activity of many rules" (1992, p.174) and describes it as a fundamental characteristic of what he calls "classifiers", which are in fact all adaptive and evolutive complex systems, i.e. not the simple monocausal processes. Examples of this type of systems can be ecosystems, the human brain, automata endowed with adaptive behavior.

He comments: "Parallelism makes it possible for the system to combine rules into clusters that model the environment, providing two important advantages:

"1. **Combinatorics** work for the system instead of against it. The system builds a "picture" of the situation from parts, rather than treating it as a monolithic whole...

"2. **Experience** can be transferred to novel situations, such as a "red car on the side of the road with a flat tire", the system activates several relevant rules, such as those for "red", "car", "flat tire", etc.

"When "building-block" rules, such as those for "car", have proved useful in past combinations, it is at least plausible that they will prove useful in new similar combinations. To exploit these possibilities, the rules must be organized in a way that permits clusters of rules to be activated in changing combinations. Building-block rules then give the system a capacity for transferring experience to new situations" (Ibid).

The whole of HOLLAND's book is dedicated to explain in detail how such rules work in natural systems and how they could be introduced in complex artificial systems. This last field is now in full development (f. ex. "artificial life" and "genetic algorithms").

HOLLAND distinguishes "intrinsic" parallelism, proper to the system itself, and "implicit" parallelism, as the "implicit" workings of the algorithm (Ibid, p.X).

2470

PARALLELISM (Different types of)^{1) - 2) - 5)}

(What is described hereafter are the various degrees of parallelism that may be conceived for computers. However, these notions seem very valuable for the understanding of *any* parallel **process** in very **complex systems**, as for example the **brain** or human societies).

"**Replicative parallelism**... Each **transputer**... replicate and execute the same **code**, but on a different **set of data**. This form of independent parallelism (the **processes** do not communicate much) is quite trivial" (T. MUNTEAN, 1988, p.1319). Indeed, this is practically a "multi-sequentiality".

"**Geometric parallelism**: or "**data structure oriented**" maintains more or less the same **code**, carried out by each **processor** endowed with the responsibility of one **data subset** only... The price to be paid for geometrical **optimization** of a **data** in a **machine** is an extensive **communication**. Indeed local computing in an area may obtain **data resulting** from computing in nearby areas or on farther away **processors**" (Ibid.).

The word "resulting" shows that this is organized sequentially from multiple **simultaneities**, defined by a "Principle of **locality**", as it is called by the author.

"**Algorithmic parallelism**: Each **transputer** carries out only a small part of the **algorithm** or **program**. And the **data** cross the **net** from **transputer to transputer (data flow)**. The **communication** between **processors** must be elaborated and efficient and the work load must be correctly distributed" (Ibid.).

Obviously, in this last case, **communication** must be constrained by the **algorithm** to obtain a **net** sufficiently organized to be coherent and yet, not totally overconnected. It remains to be seen if it would be feasible to create **self-organizing algorithms**, able to develop themselves from some initial **configuration**, using the **interactions** between the system and its **environment** for internal **learning**.

2471

PARAMETER²⁾

"Any of the numerical constants which appears in a mathematical expression of **relationships** among **variables**" (T.F.H. ALLEN & T.B. STARR, 1982, p.275).

or

"A **variable** or an arbitrary constant appearing in a mathematical expression, each value of which restrict or determines the specific form of the expression" (American Heritage Dictionary, p.951).

or

"The **input** to a system which determines its **mode of operation** and thus defines what kind it is" (K. KRIPPENDORFF, 1986, p.57).

In a more general, but less precise sense: a determining factor.

This is what ASHBY expresses in the following way: "Given a system, a **variable** not included in it is a **parameter**" (1960, p.71).

2472

PARAMETER (SYSTEM)^{1) - 2)}

"A system property which has a universal **domain** of application, i.e. which can be ascribed to any system" (I.V. BLAUBERG, V.N. SADOVSKY and E.G. YUDIN, 1977, p.184).

These authors adopt this term forged by A. UYEMOV and give the following examples of system parameters:

"A system is **autoregenerative in elements**... if it is capable of regenerating its **elements** in the **process** of functioning.

...and it is **autoregenerative in relations** (or relation autoregenerative)... if it is capable of restoring **relations between elements**" (Ibid).

These two system parameters have, jointly, the same **meaning** as MATURANA and VARELA's **autopoiesis**.

The authors add: "If a system is capable of regenerating its **elements** or **relations** under the effect of other systems it is called **externally regenerative in elements** (externally determined **element** regenerative)... or **externally regenerative in relation** (externally determined **relation** regenerative).

"The system is **immanent**..., if the **set of elements** and the **set** of correlates of the system forming **relation** coincide.

"If the system is destroyed when a single **element** is eliminated it is called **minimal**...

"Systems preserving their **identity** under structural **changes** are **structurally stable**" (Ibid).

This list of systems parameters can be much extended. The notion seems close to the concept of **isomorphy**.

2473

PARASITISM¹⁾

Condition of a system which requires **energy** and/or **information** from a host system from which it depends totally for its **survival**, without any benefit for its host.

Ectoparasites perforates the **boundary subsystem** of their host, fixing themselves on the outer side of the **boundary**. Endoparasites introduce themselves into some inner **subsystem** of their host.

The parasite differs from the **symbiont** or the **commensal**, which are beneficial or neutral for their hosts.

A. RAPOPORT comments: "As a rule, parasites introduced from the outside can be combated by the immunological **reactions** of the host against the biochemically 'foreign' invaders.... In general, *successful* parasitism depends on a **simulation** by the parasite of characteristics that the host 'recognizes' (mistakenly) as its own" (1969, p.25).

Parasitism also can be social, as seen by numerous examples in insect societies... and possibly in human ones, where some **groups** live off the social production without retribution in any visible way.

In parasitic **situations**, "what one **group** gains is what another **group** loses", as stated by MARUYAMA, who considers this a **zero-sum game**. This author describes also **symbiosis** as a **positive-sum game** and mutual destruction (mutual "**antibiosis**"), a **negative-sum game** (1976, p.204).

However, in many cases this is merely a transient **situation**, as when the parasite destroys or kills the host, bringing about its own elimination. Parasites escape from this fate only if their parasitic **state** is permanently tolerable for the host, or if they are a **phase** of a **cycle** affecting successively various hosts, or if they have a life **cycle** with a **phase** of **autonomous** life.

Recently C. ZIMMER gave a number of examples where apparently strict parasitism can be useful for the host in some quite covert and unexpected way.

He also observed that some parasites are able to subtly manipulate their host's **behavior** for their own ends (2000 and M. RIDLEY's review, 2000, p.48-9).

In both situations, parasitism fosters **adaptation** and, in ZIMMER's view, even probably **evolution**. It would be interesting to find out more about this **mechanism**, even possibly between **groups** in human societies.

2474

PARETO's PRINCIPLE¹⁾²⁾⁵⁾

A **rule** according to which 20% of the people concentrate 80% of the **resources**, or income.

Similar types of **ratios** are known, as for example **Zipf's Law**, which says that in a sufficiently large collection of **elements** (as for instance the words in a book) the second most numerous item will occur about half as often as the most common, and so on in an inverse ratio: 3rd / one third, 4th / one fourth, etc.

Pareto's Principle seems thus closely related to **power laws** and **order parameters** (HAKEN) and to WEIERSTRASS **renormalization function**, which defines an inverse relation between **frequencies** and **amplitudes**. Such inversely proportional relations appear in a number of natural **phenomena** (earthquakes, hurricanes) or economic ones (markets fluctuations and crashes).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Similar **complementary ratios** are showing now in the electronic world web, where some few sites have many pages when most others have quite few. The same relation seems to exist among a few much visited sites and many rarely visited ones.

Thus Weierstrass, Pareto, Zipf, Haken and probably others have discovered the same basic **model** under different guises. The status of the model is clearly systemic in its most general **isomorphic form**, which is probably a generalized power law or its mathematical expression as the renormalization function.

→ **Self-similarity**

2475

PARRONDO's Paradox ²⁾

According to PARRONDO's paradox, it is possible to win at two loosing **games** by switching from one to the other

(It is a kind of jumping from one position to the other by exploiting the **random** movement of the **elements** in the game, similar to **randomness** in **Brownian motion**)

In the opinion of the physicist P. DAVIS and E. KLARREICH, the paradox could have significant implications related to the origins of life

2476

PARSIMONY (Law of)

→ **Occam's Razor**

2477

PARSIMONY (Requisite) ^{2) - 3)}

The necessity to avoid that "the **rate of flow of information** to the designer... exceed processing capacity" (J. WARFIELD, 1995, p.126)

WARFIELD even enounces a "Law of **requisite parsimony**", related to the fact that "Every individual's **short term brain activity** lends itself to dealing **simultaneously** with approximately seven items (a number that is reached with three basic items and four of their joint **interactions**)" (p.125).

If the law is not respected, **overload** sets in, and some **data** are not registered or **interactions** not perceived.

WARFIELD comments: "If the law of requisite parsimony is being unknowingly violated, one would expect that the impact would be revealed in the failure of large systems **design**. This is precisely what is being observed all around the world" (p.126).

The subject is related to the problems posed by **aggregation** and **underconceptualization**. Satisfying simplification through **aggregation** is more easily obtained through systemic **models**, out of which good **criteria** about **levels of interactions** can be obtained.

→ **"Algorithmic compression"** (as a possible tool for parsimony)

2478

PART ¹⁾

Any connected **element** in a system.

A part is a **whole** in itself *plus* its **connections** with other parts and *less* the **constraints** that result from these **connections**. This implies that its **identity** is somehow modified in a "social" sense and that a part severed from the **whole** for study is not the same thing when integrated in the system

In a **complex system** there may exist parts made of subparts, at different **levels**. We better should call the former, **subsystems**.

Any part has a specific **functional** value and a **positional value**.

As they are generally integrated within **subsystems**, they are mostly *locally* interconnected. However, in some cases a part can be connected with different **subsystems**, in most cases in an on-off way, or through oriented or polarized subparts.

2479

PARTICIPATION ⁴⁾

The active involvement of – if possible – all the **stakeholders** in the **design** and **management** of the system they are **parts** of.

M.E. DODDS and G. JAROS write: "Specialized **hierarchies** with separation of authority and responsibility have lost their **effectiveness** and **efficiency**".

This is a result of the evermore intricate character of great modern **organizations**, in which no one can anymore know every important aspect, nor even clearly see why some aspects are relevant.

On the other hand, **stakeholders** are becoming, by need, evermore qualified, reflexive, and even sophisticated.

DODDS and JAROS conclude: "... over the past decades we have learned that one cannot develop others, although one can facilitate their self-development. Managers are beginning to learn, and politicians are hopefully soon to learn, that one also cannot *control* others anymore... Empowerment of people and empowerment of nature are both required" (1994).

These new features in **sociosystems** explain the emergence of new ways to manage **problems** and design systems.

→ **Design conversation, Generic Design, Heterarchy, Problem.**

2480

PARTIPOTENTIALITY ²⁾

The character of "a **living system** which does not itself carry out all **critical subsystem processes**" J.G. MILLER, 1978, p.18).

"A partipotent system must interact with other systems that can carry out the **processes** which it does not, or it will not survive. To supply the missing **processes**, partipotent systems must be **parasitic** on, or **symbiotic** with other **living** or nonliving **systems**" (p.18-9).

The evolution of numerous individuals toward a growing degree of **symbiosis** could be considered as a significant step toward **sociality**, i.e. to the **emergence** of a system integrated on a higher level of **complexity**.

2481

PARTITION ²⁾

The division in **subsets** of the **model** of a system.

St. BEER writes: "Obviously **sets** can have **subsets**. The commonest form of partition in ordinary life, and particularly in the company **organization**, is to define a **set** of **subsets** which exhaust the **set** and do not overlap" (1968, p.106).

This may be needed in order to construct a manageable **model** of the system. We should however remember that no-overlapping is fictional: without overlaps, the system would not be connected, and so, would not be a system at all. An uncomfortable result of this is pointed out by M.C.LE DUC: "To date, nobody has conceived a general, teachable and explicit method for partitioning problems. Most scientific papers do not articulate how and why a particular partition, and not another, has been chosen. **Analysis** is an intuitive **process** that a competent scientist has learnt by experience. The worst result of this precept is that many take the **part** for the **whole**... Just walk into an hospital or a university" (1992, p.919).

A. EDWARDS fractalization of **VENN diagrams** seems to open a way to partition without loss of **connections** (1989).

2482

PARTITIONING ^{2) - 4)}

The progressive formation of specialized **subsystems** in a **self-organizing** system.

This seems to be a very general systemic **process**, from stellar systems to **ecosystems** and **living systems**, and social ones (social insects, enterprises, **organizations** and bureaucracies).

It could be related to LOTKA's "world engine" and, from another viewpoint to KAUFFMAN's "frozen cores".

2483

PATCHINESS ^{1) - 2)}

The character of an irregularly checkered **environment**.

Patchiness results of **disturbances** which impair or destroy in a more or less **random** way **parts** of a natural or artificial **environment**. The general result is a differentiated

mosaic. Once in existence, "...patches have differential susceptibility to a unit of **disturbance**" (S.R. REICE, 1994, p.431). There are thus **feedbacks** between **disturbances** and patches. This allows for possible **evolution** of the **environment** and variable impacts on the systems interacting within it.

2484

PATH

→ Graph

2485

PATH DEPENDENCE¹⁾⁴⁾

The way future **events** and **behavior** become oriented by former events or **decisions**.

Some of these may even have been accidental or defined by **random choice**.

Interesting historical examples are the accounting technique, the metric system, the progressively universal use of some technical innovations as for ex. traffic lights, including their color **code**; and the generalization of similar **ideographic signs** in airports and railway stations.

This is a logical result of system design oriented toward economy of **resources** and **reduction** of **redundant learning**.

→ Ideograms

2486

PATHOLOGY of complex systems^{1) - 2) - 4)}

The study of global disfunctions in systems, as well as of **disturbances** in the **interconnections** between **subsystems**.

The traditional **reductionist** attitude leads to a dismembered view of systemic **symptoms**. However, illness is not always so much as of an **organ**, or an individual, or a group, but as of their **interrelations** with other **organs** or individuals or **groups**, at the same or at different **levels**. Thus systemic pathology should study **communications** problems, at their physiological, technical and/or **informational levels**; **regulators** and **controls** malfunctions; global **governance** problems; etc...

H. SELYE research on **stress** was a partial, but important step in this direction. In such way a general pathology of **complex systems** could be constructed. (Ch. FRANÇOIS, 1984). Important applications in **management**, economy and social sciences would then be conceivable.

Among the most important systemic pathologies we can list the following:

- Progressive disorganization of internal **communication lines** in the system, leading to loss of **coherence** and capacity of **reaction** due to insufficient or delayed **information**;
- Internal **overcrowding** or **overstocking** of the system, leading to exhaustion of vital **resources** and progressive destruction of the system;

- Asphyxia of the system due to the sudden or progressive curtailment of needed **energy**, **matter** and/or **information inputs**, caused either by **changes** within the environment or internal **malfunction**.

- Overtaxing of **environmental resources** or capacity to absorb **outputs** (either useful or wasteful);

- Confusion in **coding** and **decoding**, leading to progressive loss of the capacity for meaningful **interactions** among the **subsystems** or members of the system;

- Loss of **adaptive** capacity, characteristic of **ageing processes**;

- Unbalance or downright incompatibility between simultaneous or sequential **goals** (for example between local and global, or **short** and **long term** ones);

- Misunderstanding of natural **regulations** or use of ill-conceived **controls**.

Many more aspects of systemic pathology could probably be discovered and usefully researched.

→ Diagnosis

2487

PATRIMONIAL ACCOUNTING⁴⁾

A still unexistent accounting **method** that should keep account of used-up **resources**.

The absence of any **method** to account for the disappearance of non-renewable, or very slowly renewable **ecosystems resources** is a glaring gap in general economy accounting, which states only actives and forgets passives.

This is merely the nonsystemic accounting of plunder. It maintains a false **assessment** and **understanding** of the supposed **development process**, because it does not enter in the books the price future generations will have to pay for the renewal of used-up **resources**, or even their definitive or very long-term loss, which possibly will render unsustainable our present standard of life (even where it is still miserable).

W.D. GROSSMANN and K.E.F. WATT observe: "Financial accounting is misleading when hidden **costs** (to the public, to **resources**, to future generations and to **ecological systems**) are not calculated. The most striking example is the calculation of gross national product. For example GNP increases if **ecosystems** are damaged and afterwards repaired" (1992, p.21). Also the British economist E. MISHAN has given startling examples of the same evaluation procedure, which in GROSSMANN and WATT's words: "is a formula for destroying the planet as quickly as is economically profitable (as) it discourages any kind of savings, investment, or husbanding of planetary **resources** for which the pay-off would appear largely in a distant future. This means that societal **decision-making** is being run off a theory which at its roots guarantees ultimate destruction of most planetary **resources**". The authors suggest:

"One way around this is to measure all present investments, and future overheads and gross profits in units of **matter** or **energy**, for which interest and inflation rates are irrelevant in their present form" (Ibid). The American economist D. PIMENTEL has made similar comments on the illusions about agriculture's productivity when direct and indirect **inputs** of **energy** are not taken into account.

Economists should invent systemic accounting!

2488

PATTERN^{1) - 2) - 3)}

"...an aggregate of events or objects which will permit in some degree... guesses when the entire **aggregate** is not available for inspection" (G. BATESON, 1973, p.383).

The "**aggregate**" must be somehow **ordered**, i.e. have some systemics characteristics, because no pattern is possible without more or less regular **interrelations** between these **events** or **objects**. Or at least, some **interrelations** must be postulated by our **brain**, which does not necessarily means that they are a very good **map** of reality. Copernican and Newtonian cosmical patterns were more accurate than Ptolemaic ones, and Einsteinian ones still better.

E. LASZLO states that "... **structures** are pattern-conserving and... innovations, as well as external **disturbances** are pattern-transforming" (1974, p.35).

2489

PATTERN AS A METAPHOR^{2) - 3)}

T. VAMOS et al. state that patterns have generally the character of a metaphor: "...**sets** of coherent **data** (that) are stored as learnt devices for **survival**" (1992, p.1609).

They add: "The pattern metaphor as an external view of **knowledge representation**, i.e. a self-reflective **representation** of the mental **representation** is a natural development (of the entire phylogenic **evolution** of living creatures)" (Ibid).

A very good example of metaphoric pattern is our grouping of stars that are generally without any relation whatsoever into "constellations". These groupings have many practical uses, but their unity is a mere perceptive illusion, that is even different from culture to culture: Chinese constellations for example, are different from the Western ones.

2490

PATTERN CLOSURE^{3) - 5)}

The ability of the **brain** to contrive the illusion of complete visual, auditive or tactile **perception** from an incomplete one.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

K. SAYRE explains: "If a pattern is particularly well established within the **subject's** perceptual **repertoire**, **simulation** of a **subset** of its operating sequences may engage the entire **set** of **information-processing activity**" (1976, p.158).

Shifting pattern closure is responsible for **figure-ground** or figure-figure reversals as for instance in the famous old-woman, or young lady picture. Pattern closure is closely related to **Gestalt perception** and, generally **organizational closure** in the perceiving observer.

2491

PATTERN COMPLETION ¹⁾⁵⁾

"The ability to fill in missing or incomplete patterns so that the entire pattern is perceived rather than a partial pattern" (M. CAUDILL, 1992, p.48).

2492

PATTERN DIVERSITY in SPACE OCCUPATION ²⁾

The extent to which living **organisms** of the same species organize themselves spatially (J. SIRGY & R. GILES Jr., 1986, p.236).

These patterns can be "solitary, clumped, **random** and uniform. These are all spatial, but are related in **time**" (p.240).

The "clumps" may be of very varied types. In territorial occupation, they may be geometric, for example, square, **hexagonal** and/or concentric.

They may also be **random**, **clustered** (in very various ways), or regular (also in various ways). The same pattern can reappear at different **scales**, as for example in **fractals**.

They generally organize from simpler patterns and are **time-directed** and **time-binding**.

They appear in territorial **organization** in general.

2493

PATTERN GENERATOR ²⁾

J. COLLINS writes: "Scientists believe that insect locomotion is controlled by a **network** of nerve **cells** called a central pattern generator (CPG), which produces **rhythmic signals**. Pattern generators are also involved in many other forms of **rhythmic behaviour**, including breathing, chewing and sleeping" These CPG, presently a focus of study in insects, could lead to valuable explanations of **behavior** of more complex animals. Mathematicians have taken up the subject and "have found that the best mathematical **models** for CPGs are networks of **coupled oscillators**" (1994, p.36-7)

COLLINS' stimulating paper also connects CPGs with **symmetry-breaking processes**. It would be interesting to investigate and try to pinpoint CPGs in many other "rhythmic" – i.e. **periodic** - **processes**. This could lead to many other systemic conceptual connections.

→ **Dictyostelium discoideum**

2494

PATTERN MAINTENANCE ²⁾

The relative or cyclical **stability** of **interrelations** between **elements** and/or **subsystems** in a system.

Pattern maintenance is a condition for **homeostasis**.

It corresponds to the conservation of functional **efficiency** in social as well as in **living systems**.

Rupture of established patterns implies always a very dangerous **situation**, even when it marks the **transition** toward other types of patterns.

2495

PATTERN MATCHING ⁵⁾

"The capability of correlating an overall pattern of **input signals** of any type with an **output signal** of some arbitrary type" (M. CAUDILL, 1994, p.18).

An example is matching the face of a friend with her/his name.

2496

PATTERN (Meta)

→ **Metapattern**

2497

PATTERN RECOGNITION ^{2) - 3)}

The way a system retraces **structures** and **processes** regularities, becomes able to register them and to use this **information** later on.

Pattern recognition is a very important systemic **function**. It seems to have two different aspects.

First, a pattern must be discovered and identified. This implies the recognition of various coherent steps in a **process**, or of the **coherence** of various **elements** in a **gestalt**. Once the pattern has been identified, the corresponding **information** must be kept.

Once recorded, the pattern can be "re-cognized" when the same **process** or **gestalt** reappears.

Different forms of pattern recognition **processes** are present in immunology, cerebral **activity** (see for ex. **STEINBUCH matrixes**), **artificial intelligence** and social **activity** (for ex. in all types of **languages**, in **stigmergy**).

2498

PATTERN (Rules generated) ²⁾

Practically any kind of complex patterns can be generated by an appropriate **set** of rules, at least in a **structured space**, invariable in **time**.

Rules for creation, **reproduction**, ways of propagation, **survival** and destruction of **elements** are needed.

The idea of rules generated patterns led to J.von NEUMANN **cellular automata**, to J. CONWAY's **game of life** and to M. MARUYAMA **mutual causal (deviation-amplification) models** of systems self-construction.

Generating rules are also fundamental for the development of **networks**.

Some rules generated patterns may become partly or totally stabilized with **time**, i.e. are potential **genetic algorithms**.

2499

PATTERN (Temporal) ²⁾⁴⁾

A sequence of **events** or **actions** characterized by a **configuration** well distinguishable from other configurations and that may be repetitive.

A frequent example are birdsongs. The same bird may repeat many times a typical sequence of notes. Or birds of the same species may transmit a similar song **pattern** from generation to generation.

D. GERNERT recognizes a variety of temporal patterns: "**pattern generation**, pattern transfer, **pattern recognition**, pattern interpretation and pattern application"(2000a , p. 158)

He recognizes such patterns for example in molecular biology and in developmental biology.

It is however obvious that temporal patterns can be observed in many fields under the guise of periodic **processes**, which may even be **self-similar**

→ **Self-similarity in the Weierstrass equation ;Fields within fields within fields; Morphic field**

2500

PATTERNED RELATIONSHIPS ²⁾

The more or less permanent or recurrent **connections** between the **components** of a system (after B. BANATHY, 1973, p. 88).

BANATHY explains: "These **relationships** make up the interactive **functions** that **components** carry out by **design** and that display the **structure** of the system" (Ibid).

This concept is obviously related to MATURANA and VARELA'S **organizational closure**. However, if the system must be designed, then its **organizational closure** should be programmed... if this can be possibly done!

2501

PATTERNING ²⁾

The discovery or ordering of specific and repetitive **interrelations** between associated **elements**.

The discovery of any pattern implies that the associated **elements** are **parts** of a system.

G. BATESON writes: "... patterning or **predictability** of particular **events** within a larger **aggregate of events** is technically called '**redundancy**'" (1973, p.382).

In fact, **predictability** results from the discovery of patterns. Patterning is also a tool for **compression of data**, leading to construction of **algorithms** (see: **Algorithmic incompressibility**). It seems to be a basic ability of the brain.

2502

PATTERNING (Dynamic) ²⁾

"The aggregate **effects of energy flows** which emerge from collective or aggregate **relation in networks**" (V. ROWLAND, 1976, p.121).

This **effect** corresponds to the **synchronization** of interconnected **effects**.

ROWLAND gives the following example: "Electrical generators with their own **governors** vary somewhat around the 60 cycle **frequency**. When connected up in **parallel**, however, those generators running too slow are speeded up and those too fast, slowed down. The combined compensations of the whole **network** produce a very stable 60 cycles per second. However, if these generators are linked up in series they do not stabilize each other in terms of the electrical **feedbacks** inherent in a **parallel** arrangement.

"Thus... the dynamic patterning refers to a stabilizing of a **frequency** which is produced not by the **elements** of the system but rather by the manner in which they are interconnected or related" (Ibid).

The same effect also appears, for example, in ASHBY's **homeostat** and has been shown by KATCHALSKY et al. to exist in brain cells assemblies (Ibid).

It is also present in **ecosystems**.

It is the result of the existence of various **initial conditions**, submitted however to a basic global superseeding **determinism** (See: **chaos**).

Dynamic patterning is a very basic **coherence condition in networks** and **complex systems**, in which it provides a diffuse and distributed, but at the same time, global **control**.

In accordance with PRIGOGINE's extension of **thermodynamics** to **open dynamic systems**, ROWLAND also observes that dynamically maintained patterns: "... require the **dissipation of energy** for their **maintenance**" (p.123).
→ "**Oscillators (Coupled)**"

2503

PATTERNS ASSOCIATION ²⁾

The formation of associations between patterns is a very important ability of neural **circuits** in the **brain**.

It corresponds to a **phenomenon** thus described by P. DENNING: "... the **memory** is sparse because the physical locations are a vanishingly small **subset** of the **memory space**; it is distributed because a pattern is stored in many locations and retrieved by statistical reconstruction from many locations. **Distribution** enables the **memory** to retrieve a stored pattern when the **input** cue only partially matches any stored pattern, an ability that arises from the large overlap between the spheres of selected locations of two similar cues" (1989, p.334).

Patterns association is now researched on **connection machines**, as another example of **feedback** between **parallel computer** research and **brain** neurology.

2504

PAY-OFF ¹⁾²⁾⁴⁾

In mathematical, **game theory**, the **gain** or loss of a player.

It can be formalized through a pay-off **function**.

The concept of pay-off may however lead to an oversimplified view of more complex **issues**, not reducible to game theory.

The ecological "game" (and probably in the long run the economic global **gain**), for ex. is implicitly based on the **stability** and supposed inexhaustibility of the environmental **resources**. This leads to probably illusory **models of positive-sum games**, i.e. obtention of pay-offs ...that must never be payed for, since natural **substrate** is the invisible loser

Any game theory concept applied to complex **issues** should be at least two-tiered, i.e. complemented hierarchically by a super-game of players against the **environment**.

Permanent **carrying capacity** should be monitored, and this could possibly be done through national and planetary **patrimonial accounting** of natural renewable and non-renewable resources.

→ **Commons; Economics in systemic terms**

2505

PERCEPT ^{1) - 3)}

1. "The basic unit of experience" (W.T. POWERS et al., 1960, p.63).

POWERS et al. state that "It is that '**bit**' of **perception** which is self-evident to us, like the intensity of light, or the taste of salt" (Ibid).

"Self-evidence" is always somewhat dubious and it is possibly not *that* simple: How do we connect percept with **gestalt**? Is **gestalt** already an integrated **set** of percepts? What about the synthesis of color, verticality, horizontality and three dimensionality in visual percepts?

A. BRAVOS and P.H. GREENE, who propose a similar definition, list the following basic percepts: "... spatial orientations such as verticality (up-down), relative positioning (front-back and near-far), containment (in-out), horizontality (path), and various internal and external forces such as discomfort, pleasure, effort, compulsion, novelty, boredom, and cold, light and dark" (1992, p.1586).

The establishment of percepts – and still more so of concepts – is thus conditioned by existing basic **contexts**, as for example gravity or electromagnetic waves.

As to concepts, their existence postulates in an implicate way that all living beings (or at least all living beings on this planet) have more or less the same basic physical sensations, as for example phototropism as a response to light.

As to the supposedly more or less similar internal effects of sensations, human beings are trapped within their humaneness. (What does the dog see when we see "red"? And even, is seeing "green" for you the same than for me?)

As advocated by W. FRITZ, it would be interesting to scrutinize the possibility of endowing artificial beings with complex **arrays** of percepts (1984, 1989).

From a different perspective, G. PASK writes: "A real **observer** is able to recognize some, but not all, possible forms of **behavior**. These recognizable forms are his percepts and there is a finite **set** of them" (1961, p.21).

This set can however be extended: "Individuals circumvent their imperfections by forming a simplified **abstraction** of the real world, through **learning** and concept formation (as a result of which, amongst other things, they learn to recognize new percepts)" (p.22).

2506

PERCEPTION ^{1) - 3)}

1) An effective adaptive internal **response** to a **stimulus**.

This is merely one way to view perception. The subject is and probably will remain widely discussed and controverted. The following quotes only introduce some characteristic, more or less systemic views.

R.L. ACKOFF and F.E. EMERY add to the definition that the **stimulus** should "... produce a **change** in at least one **structural** property of the respondent" (1972, p.66).

Perception implies of course an **observer**, whose **phenomenological** and **epistemological** status is quite difficult to determine (see von FOERSTER's comments on the **observer** and "**Observing systems**").

J.J. GIBSON for ex., states: "Perceiving is a psychosomatic act, not of the mind or of the body, but of a living **observer**... It is a keeping in touch with the world, an experiencing of things rather than having an experience. It involves awareness-of instead of just awareness" (1986, p.239 -40).

For K. SAYRE: "Perception occurs within a cascade of **information channels** originating at the surface of the perceptual **object** and terminating in the cortex of the perceiving **organism**...

"This characterization is general enough to hold true independently competing views about the nature of the intermediate stages. It is true for someone (like ARISTOTLE) who holds that **structure** present in external **objects** are conveyed directly to the sensorium of the perceiving **subject**, as well as for someone (like LOCKE) who holds that there are intermediate **objects** (such as sense-data) of which alone the **subject** is directly aware. It is true for someone (like BERKELEY) who treats perceptual awareness as a passive **response** to external influences, as well as for someone (like KANT) who emphasizes the participation of the mind itself in the formation of the **structures** of which we are aware" (1976, p.153).

Of course, such an omnibus explanation does not explain much about "the nature of the intermediate stages".

From another angle, D. Mac KAY writes: "It is not denied that in **observer-language** we can distinguish two stages. Of all the **objects** in the **field** of vision, for example, only a few are normally perceived at any one **time** – those that have "caught the attention" as we say. **Stimuli** corresponding to the presence of the others are received; but they evoke no "matching **response**" in the **organism**" (1956, p.105)... "at least none structured to correspond to the individual **objects**. These **objects** are not *perceived*" (Ibid, p.61).

This corresponds obviously to BRENTANO's perceptive intentionality. Also, as expressed by von FOERSTER: "The keys to perception are not only the sense **organs**, but moreover in their **interaction** with the **motor** system" (1992, p.76).

2) "The adaptive updating of the **state** of orientation" (of the system) (D. Mac KAY, 1969, p.98).

According to Mac KAY: "A solitary **organism** keeps its orienting system up to date in **response** to physical **signs** of the **state** of the **environment**, received by its sense **organs**" (Ibid).

An integrated system also perceives – at least up to some point – what happens inside itself.

2507

PERCEPTION (Constancy of) ^{2) - 3)}

K. LORENZ emphasizes the importance of acquired constancy of perception as a condition for **survival** of **living systems**. He distinguishes particularly constancy of **form**, of direction and of color (but various other types of perception could be mentioned) and more or less equates the **process** of constancy acquisition to the formation of **Gestalt** (1962, p.44-47).

Living systems do progressively construct and stabilize perceptive **algorithms**, probably through **organization** of **neural networks**.

Constancy of perception is obviously an extremely important aspect of **organizational closure**, **autopoiesis** and **autonomy**.

2508

PERCEPTION (Dispersed) ¹⁾³⁾⁵⁾

The **simultaneous perception** by different senses organs of distinct characteristics of the same **object**

Sometimes even, the same organ seems to perceive separately various features of the object and connect them in a significant **synthesis**...or differentiate them by shifting from one **receptor** to another.

ASHBY notes for example that "In the skin are histologically-distinguishable receptors sensitive to touch, pain, heat and cold. If a needle on the skin is changed from lightly touching it to piercing it, the excitation is shifted from the "touch" to the "pain" type of receptor; i.e. **dispersion** occurs"(1960, p. 180)

Perception of **space** offers another example. It is in fact a complex **synthesis** of specific perceptions of verticality, horizontality and deepness.

2509

PERCEPTION (Ecological) ^{2) - 3)}

J.J. GIBSON developed an ecological theory of perception akin to J.von ÜEXKULL's "Bedeutungslehre" (Science of **significances**) (1934, 1979). He writes, for instance: "Knee-high for a child is not the same as knee-high for an adult, so the **affordance** is relative to the **size** of the individual" (1986, p.128).

GIBSON's theory is basically about **visual** perception ("Ecological optics"), indeed generally the most used and important tool for our **observation** of the world.

It is based on ecological **observation** by living beings, principally what these living **observers** "make" of what they see, how they see what they see and to which uses they put their perceptions (see "**affordance**": What are the uses of what they see for any of them, on the base of their *tacit knowledge*).

GIBSON's theory implies:

- 1) That perception is based on the general conditions proper to this planet: gravitation **level**, imperceptible curvature, atmospheric density and transparency (compared for ex. with the characteristics of the aquatic **medium**).
- 2) That each **observer** needs to train her/himself in ecologically satisfactory interpretations of her/his perceptions. This is tantamount to PIAGET's **ontology** of **knowledge**, to von FOERSTER's **2nd cybernetics** and to **autopoiesis**. Perception is not a **response** to a **stimulus** (a mere "brief and discrete application of **energy** to a sensitive surface") (p.57), but an act of **information** pick-up. It thus implies the **construction** of inner **rules** of interpretation, based for each species (and individual) in its sensorial equipment.

GIBSON's concept seems important for our ways to define and use perceived entities, and our relations to them.

2510

PERCEPTION (Limits to) ^{1) - 3)}

There are many significant limits to perception. D.H. MEADOWS et al. put this in the most general terms as follows: Although the perspectives of the world's people vary in **space** and **time**, every human concern falls somewhere on a space time **graph**" (D.H. MEADOWS et al., 1977, p. 19)

(See the graph "Cognitive spaces", an adapted form of the timegraph)

Physiological limits

J.P. CHANGEUX writes: "An alteration in **environmental** properties becomes an **event** for the concerned **organism** only to the point that its physical characteristics enter within the sensibility **domain** of its **receptors**. What may be an **event** for an insect, possibly will not be one for a vertebrate, and conversely. However, the diversification of **receptors** types in the superior animals allows them to perceive the **event** in a more complete manner, even if still limited and partial" (1972, p.391).

A good example is the case of the frog put in cold water, very slowly heated. As the frog does not perceive the quite progressive temperature increase, it is in great danger to be boiled before becoming aware of it.

Once the **event** becomes registered as a **signal** at the **level** of the sensorial **receptor**, it is converted into an electrical impulse or **action** potential.

"Only the **frequency** or the number of these **action** potentials may vary in relation to the **stimulus** nature or intensity and then, only within narrow **limits**...

"The sensorial **organs** thus transform the specific and various **signals** from the external world in conventional ones. When crossing the **boundaries** of the **organism**, the **signal** loses, apparently, its specificity, its **information content**. Actually, the specificity of the received and transmitted **signal** is not lost: it is taken up through the specificity of **connections**, the lines linking the sensorial collectors with specific neural relays in the nervous center" (p.39).

However, during this internalization **process**, much of the original potential **information** is lost. According to H.von FOERSTER: "Since there are only a hundred million sensory **receptors** and about ten-thousand billion synapses in our nervous system, we are 100.000 times more receptive to **changes** in our internal than in our external **environment**" (1981, p.300).

It could be added that only during this century man learned to register and *translate* through technical means some alterations of the **environment** (X rays, electromagnetic **waves**, for example) in order to enable his sensorial **receptors** to perceive them, at least indirectly: we still do not know what we would "see" or "hear" if we were sensorially better endowed.

We use these interpretations, acquired by **learning**, to observe the world around us. Such **observations** are by no means pristinely pure. Our physiological observing **subsystems** act as **filters**. We do not see, hear, smell, or feel everything that could be observed, not being able to perceive, for example, infrared, ultraviolet light, or ultrasonic waves. On the contrary, we may perfectly "see" lights or shades that are optical illusions. Thus, the **information** we obtain possess no absolute **ontological value**.

Psychological and mental limits

We perceive in accordance with our **frames of reference**, which are constructed in a progressive way by **learning** and training in specific **environments**.

In this way a painter becomes much more able to distinct shades of colors, and a musician the specific tonality of different instruments and the sounds harmonics.

In a similar fashion, a trained physician will produce better and swifter diagnostics than a student.

On the contrary, the untrained person is barred to see, hear or understand many **signs** in any specific trade.

One lesson is that the non-systemist will generally be unable to see not very obvious **interrelations** among **elements** in a system or **events** in a **situation**.

Perceptions are also oriented – or stunted – by our specific needs or interests. This is "perceptive intentionality" (See above and hereafter).

Cultural limitations

The way perceptions are trained and educated strongly depends upon the cultural settings.

Esquimos learn to recognize many important and distinct aspects of snow, while old seafarers knew much about winds and waves.

The ways to represent perspective have been very different in Western and in Far-Eastern painting.

Cultural limitations do also change through time. Modern Western perspective was unknown in Medieval painting.

Limits to perception lead frequently to serious misunderstandings between people and to deficient awareness in complex **situations**.

2511

PERCEPTION (Purpose in)³⁾

... or, in M. MERLEAU-PONTY's terms "perceptive intentionality" (1945).

In G. BATESON's words: "I, the conscious I, see an unconsciously *edited* version of a small percentage of what affects my retina. I am guided in my perception by **purpose**.

"I see who is attending, who is not, or at least I get a myth about this **subject**... It is relevant to my **purpose** that you hear me..." (1973, p.408).

Perception must by necessity be selective. Otherwise we would be submerged by it and unable to act anymore. Such a purposeful **organization** of perception is the result of the progressive **organization** of our **neural networks**, through imprinting, **training**, or **learning**.

There is however a price to pay: **selectivity** blocks us slowly in **routine** grooves and much of reality becomes **invisible**, or again, subtly *edited*. As expressed in a untranslatable German pun by H.von FOERSTER: "...was man wahr-nimmt, nimmt man für wahr" (1992, p.51).

2512

PERCEPTION (Selective)³⁾

According to H. SIMON, any person perceives these aspects of a **situation** specifically related to his/her own **activity** and **goals** (1958).

Such selectivity is necessary in order to avoid drowning oneself in the excessive **flow** of available **information** and succumb to **overload** (as could become a result of Internet overflow, for instance).

However, it may lead to a *selective blindness* or *deafness* which produce partial or total loss of **understanding** of the general **reference frame**. Moreover, in K. BOULDING's words:

"The spread of specialized deafness means that someone who ought to know something that someone else knows isn't able to find it out for lack of generalized ears" (1956).

2513

PERCEPTION (Temporal limits to)^{2) - 3)}

Living beings in general, and man in particular, are sensorily, nervously and socially ill-equipped to perceive **changes** that are slow in comparison with their **life-time**.

This leads, in the case of **human systems**, to very serious **monitoring**, **forecasting** and **planning** problems, because frequently the very most basic **trends** escape attention... until it is too late to do something very useful about it. Practical example are plentiful: Disasters in flood plains unduly occupied; **planning** disasters like the drying up of the Aral sea; overfishing in the oceans; poisoning of the phreatic tables by agro-chemicals; etc...

Mankind should urgently need qualified **long term** systemic watchmen and women.

→ Wave and tide model

2514

PERCEPTION through the mind³⁾

D. BOHM and F.D. PEAT state: "... in science, perception of similarities and differences takes place primarily through the mind (e.g. NEWTON's perception of a certain basic similarity between the apple, the moon and the earth), and much less through the senses. As science developed, this aspect of perception through the mind grew more and more important. Indeed, very little of what could be called direct senses perception takes place in physics today" (1987, p.45).

As perception grows steadily more indirect, the human **brain** seems to respond with a growing **endogenous** creative **activity**. This was surely perceived by EINSTEIN, when he proposed to use "thought experiences".

In **systemics** too, the mind seems to guide perceptions more and more, as for example through J.de ROSNAY "macroscope", or MANDELROT's **fractals**.

2515

PERCEPTRON⁵⁾

An electro-mechanical device able to recognize some **patterns** among a number of **stimuli** it is able to register.

The perceptron was developed by F. ROSENBLATT during the fifties. It consisted of a trainable **network** of connected **nodes** that interacted in such a way as to be able to "learn", at least to a limited degree.

Each **node** could do simple calculations like adding and subtracting, based on received **signals**. It was also able to emit some **signals**. To decide which **signal** to send, a **node** adds up its **inputs**, after "weighing" them through

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

very simple **mechanisms**, and thus giving them different values. Positive weights make the **node** more likely to emit if it happens to receive this same specific **signal**, and conversely, with negative weight. A perceptron is more or less progressively self-programmed, as it becomes able to define "right" answers and, by further use of the weights, to close in evermore on them, through a discriminate use of its **inputs**.

ROSENBLATT considered at the time that the perceptron was a probabilistic **model** "for **information storage** and **organization** of the **brain**", and "as a **concept** it would seem that the perceptron has established, beyond doubt, the feasibility and principle of non-human systems which may embody human cognitive **functions** at a **level** far beyond that which can be achieved through present day **automatons**" (F. ROSENBLATT, 1958, p.449)

The perceptron was shelved for many years after M. MINSKY and S. PAPERT showed in 1969 the practical difficulties for any efficient self-programmation. in order to obtain really interesting results. They proposed instead the "top-down" approach to **artificial intelligence** by the introduction of **programs** for the manipulation of abstract **symbols** representing **knowledge**, and **transformation rules**.

The same problem had also be signaled by F. OFFNER in a 1965 paper (p.195-200).

Such a critique is seemingly at the same time well founded and off the mark. The perceptron is by necessity a highly **parallel machine**, thus inevitably **chaotic** and practically unprogrammable. But, as observed by E. ANDREWSKY, such systems "do not have central units, and each of their **elements** functions in its local **environment** in order to determine a global **cooperation**, that is the system's **self-organization**. The **network** shapes itself progressively through the **stimuli** it receives; in other words, its **learning activity**, which is continuous during its implementation, results in **changes** of the **network** itself (whereas classically, **learning** is only **change** in **knowledge representation**)" (1993, p.193).

"Global **cooperation** in local **environments**" leads to the very interesting new field of **computational ecology** (B.A. HUBERMAN, 1988).

ROSENBLATT's idea has resurfaced in the eighties in the guise of the **connexion machines... or interactions among machines**. As stated by P. DENNING this was made possible when "several investigators independently discovered how to transform ROSENBLATT's perceptron **learning heuristic** into a precise **algorithm... called backward error** propagation, because errors in the **output** are used to adjust the weight applied to the **inputs**. One version of the backward **error** propagation **algorithm** was described in 1986 by D.E. RUMELHART and J.L. McCLELLAND and their colleagues" (1992, p.427).

2516

PERCEPTUAL CONTROL THEORY ¹⁾²⁾⁵⁾

Perceptual Control Theory (PCT) (in living beings) has been introduced by W.T. POWERS, who states that it "was originally inspired by the work of the early cybernetists (WIENER and ASHBY primarily)" (from POWERS internet page).

However, PCT presents a much more elaborated view of controlling as related to a wide variety of **perceptions** in living beings. This is still more so in human beings who are **willful controllers**. Their **relationships** with their **environment** is not merely biological, nor limited to "here and now". On the contrary, they are so complex as to need a very high degree of **interrelation** and interpretation. This is provided by physiological **sensors** of different kinds (now moreover aided by an **array** of enhancing artificial devices), and by the hypercomplex **organization** of **neural networks**.

POWERS introduces new notions to cover these aspects, under others **environment functions**, **reference** conditions and discriminative **stimuli**. He also expands the meaning of **amplification**, **control** and **purpose**.

2517

PERCEPTUAL FIELD ²⁾:

The **set** of organized perceptual abilities in a **subject** (After K. SAYRE).

This author contemplates the existence of several different associated perceptual **fields**: visual, auditory, tactile...

He adds: "If the objective presentations constituting a given **field** from moment to moment are focused around a constant "inward locus", this subjective locus assumes the character of self-**identity** through **time**... The **subject** thereby both provides temporal **continuity** to the individual **field** of awareness and serves as a reference by which different **fields** can present simultaneous appearances. As KANT remarked with typical acuity, while **space** is the form of all outer appearances, all inner determinations are represented in relations of **time**" (1976, p.246-7).

2518

PERCEPTUAL FILTERS ^{1) - 3)}

Any sensorial **organ** or part of the nervous **subsystem** which reduces our capacity to observe our **environment**.

Our five generally recognized sensory **organs** all act as perceptual filters. For ex., our sight cannot recognize infra-red or ultra-violet radiations, or may in some cases confuse colors (Daltonism). This renders our sight incomplete, and even in some cases unreliable.

The way sensations are translated into nervous **inputs**, and notably the ways these **inputs** are converted and become interconnected in the **brain**, may also produce a filtering or warping effect.

In this way, **ambiguities** and erroneous interpretations can appear as for example optical or auditive illusions.

Finally, some cultural traits may generate perceptual filtering effects through a different quality or **level** of sensorial education. As an example, the perception by Indian Raga musicians of 1/9th of tones is more acute than the Occidental perception of mere 1/2 tones.

The existence of perceptual filters is very important for any good theory of the **observer**.

→ **Blindspot**

2519

PERCEPTUAL PROCESS ^{1) - 3)}

"A specific **function** (**activity**, **process**) of a sensory system and of the plastic neural systems directly coupled to it" (M. BUNGE, 1979, p.152).

BUNGE gives the term "**percept**" as a synonym for "perceptual system". In order to avoid confusions with the commonly accepted meaning given to "**percept**", it seems better to retain the latter expression.

2520

PERCEPTUAL-MOTOR ARCH ¹⁾²⁾³⁾

"The perceptual-motor arch considers the **process** of **decision making** in respect to the duration from **perception** of the **current situation** to the formation and execution of the **response action**" (M. KALAJDIEVA, 1999)

This Bulgarian author comments: "The perceptual-motor arch is systematized in seven **levels** of **complexity** of intelligence. Four further levels of memorizing and retrieving efficient **algorithms** for decision-making and reaction-forming are mentioned. It is assumed that human **memory**, intelligent technologies and **knowledge** processing are far superior to nowadays computers; that programs of **reaction**, encapsulating the decision made, and evaluation technologies which are memorized, can be trained by repetition and inherited as "hardware". The investigation aims at ways to animate humans to become more sensitive to conscious **behavior** in **crises**, to evaluate and then (re-) act and enhance intelligent **agents** systems" (Ibid)

M. Kalajdieva can be consulted at the Institute of Control and System Research, Bulgarian Academy of Sciences, Sofia, Bulgaria

2521

PERCOLATING CLUSTER ²⁾

An expanding cluster of **elements** that crossed the critical **threshold** from which the **process** is able to propagate itself without restrictions in a sufficiently **homogeneous medium**.

In such a case, the percolating cluster expands itself rapidly, occupying the major part of the available **space**.

This is however generally a self-destructive **process**, or at least a self-limitating one. If the cluster is made of sick individuals, they die or cure themselves. If it is made of trees, their becoming burned trees slows down or finally stops the fire.

2522

PERCOLATION ²⁾

Propagation mode of a **process** in a **medium** or a relatively **homogeneous** system, characterized by a sudden **discontinuity** at some precise instant, depending on a **critical density** of the main **component** in that **medium** or system.

In **random graphs** used as **models** "...percolation **thresholds** occur ... and determine when large, connected **webs** of **elements** will form. Below the **threshold**, such **webs** do not form; above the **threshold**, they do" (S. KAUFFMAN, 1993, p.205).

This is a **dynamics** of contagion and apply only to almost **homogeneous** systems. The concept was introduced by the English mathematician J.M. HAMMERSLEY in 1956, and corresponds to a general **model** which permits a better **understanding** of numerous **phenomena**, as for example:

- epidemics and epizootics
- forest and bush fires
- pest invasions in fields and orchards
- mud or rock slides, or snow avalanches
- the triggering phase of numerous chemical **processes**

On this side of a defined **density** of the principal **component** of the system or **medium**, the **process** remains confined and cannot propagate itself to the whole system.

P. GRASSBERGER, using the example of a specific pest invasion in an orchard planted with various kinds of trees, observes that: "One may ask oneself if the chances of a pest to invade one by one all of the apple trees do increase regularly with the proportion of apple trees..."

"Such is not the case. Quite surprisingly, the pests chances to run from one to the other extremity of the orchard are practically nil under a certain proportion of apple trees but become practically 100% over that value..."

"Percolation functions are like an **"all or no-thing process"** (1991, p.640).

Of course, it is implied that no perturbing factor does interfere. The **situation** would be quite different if a strong wind should transport the insects far away (see **"Oriented percolation"**) or if the affected **population** members would be able to travel at great distances.

2523

PERCOLATION (Oriented) ²⁾

A percolation **process** submitted to some **constraint**, in **space** or in **time**.

In an abstract **model**, it is for instance possible to impede **propagation** in one or various defined directions.

Using the example of a forest fire, the direction of the wind may favour percolation in one direction and impede it in another one. It is altogether obvious that, when the percolation **process** implies the destruction of the affected **elements**, it will not be able to propagate itself again in zones where **populations** have already been devastated. Where the fire has raged, there are no more trees to burn and where the epidemics raged, the number of immunized or naturally resistant individuals is much higher than the one of the individuals who could yet succumb to the illness.

This **phenomenon** also shows up in the **time** dimension. A destroyed forest will need a long **time** to become again a combustible forest. In the case of epidemics, increasing **survival** of immune and immunized individuals at each resurgence of the epidemics lead normally to such a **situation** where the percolation **threshold** cannot be reached anymore, at least for long **time**.

2524

PERCOLATION THRESHOLD ²⁾

The **limit** under which a **process** cannot propagate itself in a **medium** or an almost **homogeneous** system or, on the contrary, beyond which it propagates without **limits**.

This threshold, which is expressed by a %, depends on the spatial arrangement of the **elements**. P. GRASSBERGER, using the very simple example of a bicolor **net** of square **components**, shows that the percolation threshold is theoretically at 59,29% When this **limit** is reached, percolation triggers and isolated **clusters** of the most numerous **components** percolate, i.e. become interconnected and invade the near totality of the surface, confining in turn the less numerous **components** into small **clusters** isolated from each other (1991, p.649).

In this way, for example, epidemics become pandemics.

The existence of percolation thresholds explains the better **stability** of very **heterogeneous** systems as, for example, the natural ecological systems differentiated in very numerous niches corresponding to many species.

GRASSBERGER, moreover, points out that "...in the **vicinity** of a percolation threshold, the behavioral differences between various systems become blurred and all show a *truly universal behavior* Their properties do not anymore depend on their particular **structure** but on the contrary, obey to global laws called **"scale laws"**. However, while this universality is now well confirmed, a complete mathematical formulation is still lacking. It is not always evident... how to distinguish from the start which are the universal **magnitudes** and which are the details of the **structure** which should be neglected" (p.642).

2525

PERFORMANCE ¹⁾

The results effectively obtained through a **process** or by a system, compared with the **maximum** possible or suitable **optimum**.

The definition emphasizes two different possible **criteria** for measuring performance. Of course, the **maximum** possible does not always corresponds to the suitable **optimum** because, in a **complex system**, each **subsystem** or **process** does not only work for its own benefit and, in many cases must, or should respect **constraints** needed to secure the best possible general performance of the system as a **whole**.

2526

PERIOD ²⁾

The **time span** needed for covering the successive **phases** of a repetitive **cyclical process**.

In complex **processes**, a mix of various periods at even very different **time scales** may happen and the general **cyclical** character of the **process** may remain hidden. A period, very long at human **time scale**, may also be confused with a **trend** or even not be perceived at all.

Already L.von BERTALANFFY believed that a general theory of **periodic processes** would be a necessity for various scientific disciplines (1968).

K.DE GREENE has recently returned to this study in a series of thought provoking papers (1988 to 1991).

2527

PERIOD-DOUBLING BIFURCATION ²⁾

A **threshold** in a **process** that tends to turn **chaotic**, signaled by the replacement of a period **n cycle** by a period **2n cycle**.

After such a bifurcation the repetition of a certain **state** of the system needs twice the number of time-steps. When repeated time and again these **events** are akin to a **fractalization** of the **cycles**.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

In the case of the **logistic equation**, as stated by R. JENSEN: "The range of (the **parameter**) *a* over which a single **cycle** is **stable** decreases rapidly as the period of the **cycle** increases, which accounts for the rapid **accumulation** of **cycles** with larger and larger periods" (1987, p.171).

For $a \geq 3.57$ the global **cycle's** period becomes infinite.

2528

PERIOD-DOUBLING SEQUENCE²⁾

A succession of period-doubling **bifurcations**.

Period-doubling was discovered by M. FEIGENBAUM.

An orbit on the **trajectory** is replaced by another one twice as long at each time-step *t*, while the **time** needed for a repetition of any **cycle** is twice the number of time-steps. The longer the period, the faster the period doubling and the smaller the distance between neighbouring points on the orbit: This is a **fractalization process**.

In this way the **process** acquires a growingly **random** aspect that makes it more and more difficult to observe. A **sequence** of regular **oscillations** suddenly gives way to unpredictable **behavior**, and back again to a new **pattern** of **oscillations**, and so on, but within shorter and shorter **time spans**. The **process** remains however basically **deterministic**, at least globally.

A period-doubling sequence is the signature of **chaos**.

→ "Logistic equation"; "Renormalization".
For more precise information, see JENSEN (1987).

2529

PERIODIC AND QUASIPERIODIC MOTION²⁾

"The combination of two independent periodic motions produces a **toric attractor**. A quasi-periodic orbit winds itself round the torus like cotton on a bobbin" (I. STEWART, 1989, p.45).

More than two independent periodic motions generally produce, when combined, a **chaotic behavior**. In J.P. ECKMANN's words, in such case the system may explore "in several occasions the same **instability** without **periodicity**" (1992, p.113)... Or possibly, periodicity is so complex and at such a long **time scale** that it becomes practically unobservable.

P. BERGE and M. DUBOIS describe the "three principal ways that may lead to **chaos** starting from a periodic **regime**:"

"1. by **period doubling**, for which period is doubled at each **bifurcation** until nearing a period of infinite length;

"2. By **intermittences**, for which periodic **states** slowly destabilize until there is a "puff" of **turbulence**;

"3. by quasi-periodicity, for which the **non-linear interaction** of 2 (or 3) **oscillators** leads to **chaotic behavior**" (1992, p.128).

→ Quasi-periodic

2530

PERIODICITY^{1) - 2)}

The more or less regularly recurrent and more or less similar **variations** of a **function** or a systems **behavior**.

Periodicity implies a succession of **cycles** of regular or irregular **frequencies** and **amplitudes**. The following types of periodicities could be distinguished:

- **mono-cyclical**: corresponding to only one **cycle** of defined **frequency** and **amplitude**. Such periodicity is perfectly **predictable**. In many cases, when others **cycles** with very short or very long **frequencies** and **amplitude** are present, they escape **observation** for long **time**, or they seem to be **trends** and the mono-cyclical **model** remains generally adequate.
- **commensurable, bi- or poly-cyclical**: this case corresponds to the interferences and combinations of **cycles** of various commensurable **frequencies** in harmonic relation in **phase** or out of **phase** (f.ex. 2, 3, and 6 or, more complicated, 9, 12, 27). Such periodicities are still regular and **predictable**, but more intricate, difficult to observe and complicated to analyse. In some cases, **fractal** periodicities can be found. See: "Self-similarity in WEIERSTRASS functions".
- **uncommensurable**: This case corresponds to the interferences of various **cycles** with **frequencies** corresponding to **prime numbers**. In simple cases (f. ex. 2, 3, 5, and 7), **observation** and **predictability** seems still more or less manageable, using lowest common multiples (here, 210). However, for compositions of more, or greater **prime numbers**, regularities may become practically unobservable and the system may appear **chaotic**, i.e. globally **deterministic** only in the very **long term** and this merely in case of absence of any **environmental perturbation**.

2531

PERIODICITY (Linear)²⁾

Periodicity of a **function** which can be reduced to a combination of a **set** of simple linear **functions**, even if complex.

Writes F. ROBB: "The elucidation of such **functions** has been the overriding concern of scientific analysis. The results have often passed off as causal "explanation". From this point of view, a **complex linear system** is seen as being no more than the sum of its **parts**, and the **behavior** of the **whole** can be reduced to that of a simple **operator**" (1989, p.55).

However, **complex systems** are generally **nonlinear**. This is the rule when three or more **initial conditions** act simultaneously in different **parts** of the system. In this situation, the global **determinism** becomes highly complex and leads to a growing **randomness** which makes the **behavior** of the system more or less unpredictable.

2532

PERIODICITY PRINCIPLE¹⁾

According to W. SCHWEMMLER (1991), periodicity seems to be a very basic feature of cosmic **evolution**. Such regularity would apply to the progressive **emergence** of evermore complex systems during cosmic **evolution**, through **association** and **integration** of simpler **elements**. SCHWEMMLER distinguishes four **levels** of **emergence** of this type:

- Elemental **symmetries** among particles at subatomic **level**
- Periodicity at the **level** of chemical **elements** (MENDELEEV)
- Periodicity in elemental **levels** of biological complexity (MARGULIS et al.)
- Possible periodicity in the emergent cultural genesis.

This is of course quite hypothetical, but the **similarities** of the different ways of **emergence** of **complexity** in accordance with their succession in **time** lend credibility to the idea. More research would be very useful.

C. BRESCH proposed and developed similar ideas (1977)

2533

PERSON

→ Individual

2534

PERSPECTIVISM^{2) - 3)}

I.V. BLAUBERG, V.N. SADOVSKY and E.G. YUDIN explain: "Perspectivism is founded on the idea that general **categories** of thought are similar in widely differing branches of modern science, hence the possibility of evolving a unified science on the basis of **isomorphy** of laws in its various fields. That makes it possible to speak of the **structural similarity** of the theoretical **models** used in various fields of science" (1977, p.53).

Prof. ELOHIM j.l. organized in Vienna (2002) a symposium about "Development as a Systems **Epistemology**", dedicated to BERTALANFFY's view on the subject.

He wrote: "The BERTALANFFY's perspectivism in practice oblige every learned person, while learning, to be aware of his/her relative ignorance, to recognize that using his/her **brain** to the utmost he/she must increasingly try to be aware of the **limits** of his/her powers of **cognition**, because "perception is not a reflexion of "real thing", but rather is an **interaction** be-

tween knower and known". It means that the result of every **observation** is partly the result of the viewpoint and **methodology** of the observer".

And "...all what seems to be objective perception of real **facts** and **events** is filtered by the biological features of the **observer** and his/her psychocultural achievements"(pers. comm.)

These early insights of Bertalanffy have been widely confirmed in different ways by scientists and scholars like L. WITTGENSTEIN, K. POPPER, H.von FOERSTER, H. MATURANA, F. VARELA, E.von GLASERSFELD and some others.

Perspectivism has also a more directly human and psychological value, when understood as an interactional behavior between people. This view has been developed by the Dutch andragology school, among others by W.J. WITTEVEN who writes: "The perspectivist procedure leads to comparison or arguments" and "Perspectivism requires the readiness to weight different principles in new circumstances. It requires openness to new participants in the ongoing **conversations**"(2000, p. 86)

→ **Asilomar Conversations; Cybernetics (2nd order); Facilitation; Facts as constructs; Fuschl Group; Multi-perspectivism; Ontological skepticism; Systeem Groep Nederland**

2535

PERTURBATION ^{1) - 2)}

Any input that modifies the **dynamic equilibrium** of a system or a **subsystem**, be it in a reversible or irreversible way.

The concept of perturbation is somehow ambiguous.

J.A. GOGUEN and F.J. VARELA state: "If we stress the **autonomy** of a system... then the **environmental** influences become perturbations (rather than **inputs**) which are compensated for through the underlying **recursive** interdependence of the system's **components**" (1979, p.34).

The same situation exists between **subsystems** within the system. Each of them may receive from others **inputs** that perturb it.

There is however a considerable difference between so-called perturbing **inputs**: To ingest strychnine is not, as an **input**, in the same class than eating bread, as the first one will, irreversibly, kill the system while the second one will benefit it, allowing it to return to its own type of **dynamic stability**.

Perturbations play a very important role near an **instability threshold** in systems affected by giant **fluctuations**. Such a perturbation – in most cases a **random environmental event**, or **noise** – may destroy the former organized **structure** and induce a **bifurcation**, toward a different **structuration** through **dissipation**.

However, a perturbation can have this effect only if it does not throw the system out of its **historical macro-determinism**, destroying it in the **process**.

"Perturbation" seems to be frequently used as a near synonym of "**disturbance**".

2536

PERTURBATION (Endogenous) ^{1) - 2)}

Anomalous **variation** of one or various **functions** of the system, which endangers its correct working and in some cases it very **survival**.

Any **homeostatic system** possess the capability to fluctuate inbetween maxima and minima **limits** of **stability**, generally in order to adapt itself to **variations** of its **environment**. The **fluctuations** relate in most cases to one of the **functions** or **subsystems**.

However some **fluctuations** may cross some **stability threshold** of the system, not allowing any more a return to the **steady state**. If no other **subsystem** is able to compensate adequately this **disequilibrium**, the system is heading for destruction or, in some very exceptional cases, undergoes a very radical **transformation (emergence process)**.

Endogenous perturbations are generally the final results of an **accumulation** of **exogenous variations** or perturbations. In some cases however, these are in turn a result of the systems actions. An example are cardio-vascular diseases, due at least partly to excessive smoking or inconvenient diet.

2537

PERTURBATION (Exogenous) ^{1) - 2)}

Anomalous **variation** of the **environment** which impairs the correct working of the system or of one of its **parts**.

Any **viable system** is adapted to a specific **environment**, according to its perceptive abilities, to the internal **organization** that it obtained from former systems, to the **learning processes** it underwent, and its ability to use its internal **variety** or **reserves** through its **regulation** devices.

The **environment** may fluctuate within some **limits** without endangering the system, but these **limits** correspond, of course to the **limits** of the systems possibilities of **adaptation**.

A similar idea was enounced under the guise of the "**Law of Requisite Variety**" by ASHBY.

I. PRIGOGINE states that "dynamical systems have no way to forget perturbations" (1985, p.7). A recent example of this has been the destruction of Comet SHUMAKER-LEVY 9 after having its orbit perturbed by Jupiter.

A. LIONI gives an interesting example of the way an exogenous **perturbation** may convert itself in an **endogenous** one: In a public bus line, when a unit is delayed by an environmental incident, the **delay** tends to extend itself be-

cause in the mean time more passengers have accumulated on the next stops. As a result the next units in the line crowd up with fewer and fewer passengers and the exogenous perturbation finally generates a global **endogenous perturbation** (2000, p. 149)

→ **Collective behavior; Delay amplification; Queuing theory**

2538

PERTURBATIONS in networks ²⁾:

St. KAUFFMAN distinguishes as follows minimal and structural perturbations in networks:

"A minimal perturbation is a transient flipping of a **binary element** to its opposite **state of activity**. If such a **change** does not move a network outside its original **basin of attraction**, the network will eventually return to its original **state cycle**".

"A structural perturbation is a permanent mutation in the **connections** or in the **Boolean functions** of a network. Such perturbations would include exchanging the **inputs** of two **elements** or switching an **element's OR function** to an **AND function**" (1991, p.66).

2539

PETRI NETWORKS ¹⁾²⁾

"An oriented graph used to describe the **behavior** of **asynchronous sequential automata**" (A. LEROY AND J.P. SIGNORET, 1992, p.49)

PETRI networks were introduced by Dr. PETRI in Germany in 1962. They are still in a stage of further development.

A PETRI network is made of "places" or "**positions**" which represent the static part of the network.

Tokens are moved from places to places in accordance with some **transition rules** which must be specified. Thus the network evolves from state to **state** by successive steps. During its evolution the PETRI network covers progressively all the possible states of the system under study.

It combines a structural **representation** of the modeled automata and its possibilities of **transformations**, based on the transitions rules. These can be **deterministic** with specified **delays**, or **random** ones, representing in such cases **phenomena** whose occurrence cannot be precisely forecasted.

The authors explain as follows the possible uses of PETRI nets, which sequentially follow the different successive **states** of the modeled system:

- analyse in a detailed way its sequential behavior
- identify the different states in view of creating a **markovian graph** of states
- identify the non-accessible states
- find the **lock-ins**, **delays**, **feedbacks**, etc
- discover **bifurcations** or different possible transitions (Ibid, p. 54)

PETRI networks can be used to modelize projected physical or mechanical systems and discover potential failures, **risks** or incompatibilities. (Adapted from A. LEROY and J.P. SIGNO-RET, 1992)

2540

PHASE COEXISTENCE²⁾

A characteristic of a system endowed with a **variety** of potential phases to which it can switch when necessary in order to maintain its **stability**.

As stated by R. FIVAZ, their existence "... tend to release the system from external determinants", as they "... confer to the system features independent of the **environment** such as **identity** and **autonomy**" (1991, p.25).

This **model** is closely related to ASHBY's **variety**.

FIVAZ shows that phase coexistence **regimes** are alternating with **metastability** phases. He writes: "Each of the two **regimes** influences **parameters** which determine the onset of the other regime: **metastability** increases the system **size** and eventually leads to phase coexistence, whereas phase coexistence modifies internal **couplings** so that a new **metastability** run may start. Thereby, the two **regimes** generate each other and a stage **development** takes place where **maximization** and **hierarchization** alternate" (Ibid).

This could be an interesting explanation for macro-**evolution** toward **complexity** through **structural dissipation** traded against **entropy production** increase.

2541

PHASE LOCKING²⁾

The stable dynamic **relationship** that tends to become established between **oscillators** of various **periods**. (also known as phase blockage).

The simplest cases are those wherein **periods** are equal, or have a simple arithmetical **relationship**.

It is however possible to think of phase locking in complex **interrelations** between **oscillators** of seemingly uncoordinated **periods**. An example is the progressive and spontaneous **synchronization** of pendular clocks, discovered by HUYGHENS (17th Century). The American biologist L. MARGULIS discovered various examples of biological **synchronization** in groups of bacteria and even in the menstrual **cycles** of women living in more or less secluded **groups**.

This could be the nexus with a general theory of complex **cycles**, still to be built, that should explain how **cycles** of widely different **periods** become coordinated or **embedded**.

→ "Order parameter", "Slaving principle".

2542

PHASE PORTRAIT²⁾

"The **set** of all possible **paths** along which the system can evolve" (I. STEWART, 1989, p.44).

This is the potential content of the **phase space** of the system. It is generally not possible to consider all the possible **paths**, but the selection we make must include a critique of our own **choice** and we must never forget that we remain in danger to ignore some alternative solutions, which may reveal themselves more adequate to future reality.

POINCARÉ, who ideated phase portraits, also described the **topological** properties of various singular points in them: **node**, apex, neck, focus.

2543

PHASE TRANSITION^{1) - 2)}

The crossing-over from one **state** to another in a system.

Phase transitions are a common feature in "physical, chemical, biological, mechanical or electrical systems" (H. HAKEN, 1983, p.46). The shift linked to temperature and pressure between different **states** of water is a classical example. Others are the onset of superconductivity or ferromagnetism.

H. HAKEN writes: "Synergic systems may undergo continuous or **discontinuous** transitions, and they may exhibit features such as **symmetry-breaking**, critical slowing down, and **critical fluctuations**" (p.314).

Phase transitions may appear in a stochastic way in **ergodic systems**.

2544

PHASE TRANSITIONS (Nonequilibrium)^{2) - 4) - 5)}

Instabilities that appear in a system driven far from **thermodynamic equilibrium**.

H. HAKEN states: "The nonequilibrium phase transitions of **synergetic systems** are much more varied than the phase transitions of systems in thermal **equilibrium**, and include **oscillations**, **spatial structures** and **chaos**" (1983, p.315). HAKEN also observes: "Destabilization of the former **state** in phase transitions is associated with intense **fluctuations phenomena**" (1984 - as retranslated for the Spanish translation from German!).

R. LEFEVER and I. PRIGOGINE illustrate this **process** using the **BÉNARD instability** "... a striking example of **instability** giving rise to spontaneous **self-organization**" (1986, p.2) and "chemical **oscillations** ... to occur (through) auto- or **cross-catalytic reactions**" (Ibid, p.3). (As for example the BELOUSOV-ZHABOTINSKY reaction).

Still more interesting: "Non-equilibrium transitions have also been described in the slime mold *Dictyostelium discoideum*" (p.4). This suggests that these transitions are important in all kinds of biological and **social systems**.

HAKEN went as far as to write: "The phase transitions theory allows for the identification, in the mechanisms of revolutions, of many of the **effects** observed in the natural sciences" (1984 - retranslated).

2545

PHASES in networks²⁾

St. KAUFFMAN distinguishes "solid" and "gaseous" phases in networks, which means respectively phases in which the **frozen cores** are notably more numerous than the **variable elements** and conversely. Moreover, this author states that: "...as frozen **components** melt, more complicated dynamics involving the complex **coordination** of **activities** throughout a network become feasible. The **complexity** that a network can coordinate peaks at the "liquid" **transition** between "solid" and "gaseous" **states**" (1991, p.68).

2546

PHASES SPACE^{1) - 2)}

The reference space in which all of the possible future **states** of an **object** submitted to various **parameters** are included.

It is also defined as "the **set** of all positions and velocities compatible with the system's **invariances**" (M. FARGE, 1992, p.226).

Or, in J. HOLLAND terms: "... for the **process** X, the set of all possible combinations of values for (the intervening) **variables**". (Adapted from J. HOLLAND, 1992, p.54)

I. STEWART explains: "Each **state** is determined by a **set** of numbers. Thinking of these as coordinates, we obtain a **multidimensional** space whose points correspond to all possible **states**" (1989, p.43).

Obviously:

1°- the phase space is an **abstract** one and
2°- it can be used to describe future possible **states** of the **object** or system, of which, of course, one and one only is to materialize at any future instant.

However:

1°- in most cases, it becomes impossible to pinpoint and predict some specific future **state** at some precise moment (as shown by **chaos theory**, or **topological dynamics**)

2°-... which does not imply that all the future **states** are totally indetermined, since **periodic** solutions may appear, implying the existence of **steady states**.

Moreover M. DUBOIS, P. ATTEN and P. BERGE state: "...the phase space... must contain the complete **information** about the **dynamics** of the considered system. Thus the precisely necessary and sufficient **parameters** should be

selected in order to determine these **dynamics**. Moreover these **parameters** must be independent if each one is to contribute its own **information**. This implies that, if one of them is not determined, a **degree of freedom** will subsist in the determination of the considered **states**...

"... the number of these **degrees of freedom** is of paramount importance in the appearance and for the characteristic of **chaotic behaviour**" (1987, p.194).

The conservative (or **Hamiltonian**) systems are those in which the phase space is closely restricted, while still able to contain different **trajectories**.

An interesting comment by P. BERGÉ, Y. PO-
MEAU and Ch. VIDAL is that: "If we arbitrarily increase the number of **degrees of freedom**, we can always include a **dissipative system** within more extended **Hamiltonian system**, of which it thus becomes a 'part'" (1984, p.23).

This comment reflects in a new way the unavoidable dependence of any system from some **meta-** or **supra-system**, which obeys the **2d. Principle of Thermodynamics**, but altogether, the growing **degrees of freedom** obtained from **complexity**.

D. BOHM and F.D. PEAT describe phases space in relation to a **whirl** (or **vortex**): "Imagine an irregular and changing whirlpool that fluctuates in a very complex way, but always remains within a certain region of the river... As the velocity of the river increases, this variation in **space** may grow. But in addition, there will also be an inward **growth** of subvortices of ever finer nature. Therefore, a measure of the overall **range of variation** of the whirlpool should include both of these factors – the inward and the outward **growth**... As a matter of fact, in classical mechanics, a natural measure of this kind has already been worked out. Its technical name is phases space and its measure is determined by multiplying the **range of variation** of position and the **range of variation** in momentum. The former... corresponds roughly to the **changes** in location of the **vortex** as it spreads out into the river... (and) the latter... to the extent to which the whirlpool is excited internally so that it breaks into finer and finer **vortices**" (1987, p.138).

In this way, the phases space becomes partitioned into "**Markovian** partitions" (I. SINAI, 1992, p.85)

It becomes obvious that incipient **chaos** conditions result of a growing energizing of the **vortex** and begins with the **emergence** of a finer **structuration** of the phases space.

This is consistent with Ch. LAVILLE's theory of **vortices** (1950).

2547

PHASES TRAJECTORY²⁾

A curve representing the **transformations** of an **oscillating** system within its **phases space**.

In the case of **complex systems** with various independent **initial conditions**, many future trajectories are possible (and quite unpredictable). In **chaotic systems**, the trajectory becomes totally unpredictable, even in the **short term**.

2548

PHENOME^{1) - 4) - 5)}

"The set of global properties of a system in adult **state**" (Adapted from M. BUNGE, 1979, p.100).

This concept originates in biology and physiology.

BUNGE comments: "... while every **organism** inherits its **genome**, it evolves its own **phenome** in a given **environment**: the phenome depends then upon the **genome** and its **environment**" (p.101).

The phenome reflects **adaptiveness** in systems. It would be interesting to find out if **sociosystems** acquire a phenome, and how.

→ **Phenotype**

2549

PHENOMENA³⁾

The **perceptions** we obtain from reality in itself.

The Kantian *Ding an sich* is never directly accessible to us. It corresponds to KORZYBSKI's "territory".

In BATESON's words: "The territory never gets in at all... Always the **process of representation** will filter it out so that the mental world is only **maps of maps of maps**, ad infinitum. All 'phenomena' are literally 'appearances'" (1973, p.429).

In this sense, what **General Systems Research** is trying to do is merely to find out very general and coherent **patterns** for **isomorphic representation** between the complex **phenomena** that we call systems at different **levels of complexity** (see for example A KORZYBSKI's "**structural differential**" and J. MILLER's **taxonomy of living systems**).

R. FUENMAYOR interestingly describes **phenomena** as "**distinctions** made on a **background**"

The crux of the matter is of course, who makes the distinctions and on the base of which frame of reference, or theory.

2550

PHENOMENOLOGICAL POSITION³⁾

A philosophical position which concedes primacy to the **observer's mental processes** (R. RODRIGUEZ ULLOA, 1994, p. 143)

This position contrasts with the **positivist** one that accepts the possibility of knowing **reality** through experimental evidence without taking in account any influence of the **observer** on the observed **phenomenon**.

→ **Coupling (structural); Objectivity; Observer**

2551

PHENOMENOLOGICAL STANCE³⁾

"A philosophical position characterized by a readiness to concede primacy to the mental **processes** of **observers** rather than to the external world" (R. RODRIGUEZ ULLOA, Glossary, 1999)

"This contrasts with a **positivist stance**" (Ibid)

The phenomenological stance is implicit in the **2nd order cybernetics**, the **constructivist** movement and the **autopoietic** concepts of **recursivity**, **self-closure** and **autonomy**.

2552

PHENOMENOLOGY in systemic sense³⁾

A non-philosophical, but systemic sense could be given to phenomenology, i.e. the systemic way to observe **phenomena**, and more specially complex **processes** and systems.

In such a worldview, there is a conscious "perceptive intentionality" (BRENTANO, MERLEAU PONTY), different from the somewhat naive supposedly "**objective**" view and the merely **reductionist** one.

The physiological **limits to perception**, **Gestalt** psychology, GIBSON's **affordance**, WATZLAWICZ's and von GLASERSFELD's **constructivism**, WARFIELD's **methodology** for avoiding **underconceptualization**, MATURANA and VARELA's **organizational closure**, VALLÉE's **epistemo-praxeology**, for example provide good foundations for a systemic phenomenology.

The general idea would be to complement **analytic** and **holistic observation** and **modelization** of whatever we perceive, obtaining in this way a more complete and complex, and less naive view of what we call reality.

In fact, it must be admitted that the various **concepts** of what phenomenology means and implies form a quite mystifying labyrinth. From HUSSERL to HEIDEGGER, MERLEAU PONTY and various mainly German and French philosophers, the shades of **meaning** on the subject are so distinct that a coherent view is very difficult to gather.

The Danish author O. Fogh KIRKEBY has given recently a very interesting and embracing overview on this matter. He connects also to phenomenology some significant views of WITTGENSTEIN, MATURANA and LUHMANN (1997, p. 3-33)

¹⁾general information²⁾methodology or model³⁾epistemology, ontology and semantics⁴⁾human sciences⁵⁾discipline oriented

2553

PHENOMENON (Aleatory) (or random)→ **Aleatory phenomenon**

2554

PHENOMENON (Model building of a)²⁾ – 3)

J.W. SUTHERLAND describes as follows the four analytical **levels** on which **systems analysis** can proceed to construct a more or less complete model of a phenomenon:

“ – The **state-variable level**, which finds us trying to exhaust the **array** of **structural** properties (i.e., major qualitative or static aspects) of the entity under investigation.

“ – The **parametric level**, where we try to assign some specific quantitative or categorical value to the **state-variables**, with respect to a specific point in **time** and **real space**.

“ – The **relational level**, which asks that we establish the nature of the **interrelationships** among the **state-variables** and the direction of influence (as in static comparative analysis in macro-economics).

“ – The **coefficient level**, which involves the assignment of a specific value to the relational **variables** which expresses the '**magnitude**' of the **interrelationships** among the **state-variables** at a specific point in **time** and **space**' (1973, p.144).

According to SUTHERLAND, "... a system will be **inherently deterministic** or **inherently stochastic**" (p.145). Since he wrote these lines, it as become clear that many systems are **inherently deterministic-stochastic** in the sense defined by **chaos theory**. Thus, SUTHERLAND's methodological **description** is irrestrictly valid only when applied to **linear phenomena**, but cannot be applied fully to modelize **complex systems**.

2555

PHENOTYPE¹⁾

The **set** of the observable characteristics of an **organism** as it results from the influence of the **environment** upon its genetic make-up (**genotype**).

The phenotype reflects the adaptive leeway of the **organism** in relation to the **environment**, but within the **limits** of the **constraints** imposed by the inherited **genotype**. The phenotypic **adaptation** may be due for instance to **ecological** factors (drought, strong winds, intense cold, high altitude), or **ethological** ones (invention of a new **behavior**)

→ **Phenome**

2556

PEROMONE^{4/5)}

Any chemical substance secreted by an organism that can affect or even control another **organism's behavior**.

Pheromones can attract males to females; evoke reactions of vigilance, aggression or fear; delimit territories or establish trails and tracks

Pheromones are a very basic factor leading to **collective behavior** and social **organization** in animals, through repeated reciprocal **stimulation**, that can be observed in social insects and vertebrates

In humans, pheromones are largely superseded by the use of gestural and spoken **languages**. They still seem however to exert a subtle influence on our behavior.

→ **Crowding effects; Dictyostelium discoideum; Societal order parameters; Sociality; Sociogenesis; Swarm**

2557

PHONEMES⁵⁾

"The smallest sound units that can change **meaning** in a **language**" (J.Z. YOUNG, 1974, p.297).

Basically, phonemes acquire **meaning values** only by combinations which each other, according to a specific **set of rules**: this is why a **language** may be considered as a system.

J.Z. YOUNG gives as examples the vowel i or the consonants b or t.

It should be noted that, in some **languages**, there are more phonemes than letters in the **alphabet**. An example are the French sounds, unknown in English, corresponding to the nasal sounds "an", "in", "on", "un", or vowels like "eu".

The same letter may represent different phonemes in different **languages**, as for example "u" in English, as compared with "u" in French or in Dutch, or "u" in German, Italian, Spanish and Portuguese.

2558

PHYLOGENESIS^{1/5)}

The ways of **evolution** of species.

The study of phylogenesis in living species started with Ch. DARWIN (1845-1912) (and his contemporary R. WALLACE (1823-1913)

It constantly evolved until our days, becoming connected with **ecology**, **ethology**, genetics and **populations** genetics and a host of other disciplines

An entirely new line of research appeared during the last 20 years of 20th Century through the study of artificial **neural networks**, **evolutionary robotics**, **parallel distributed processing**, etc. This new field is also known as **artificial life** and seeks to find out a general theory of **evolution of adaptive systems** of all kinds

2559

PHYLOGENY⁵⁾

The evolutionary **development** of any species of plant or animal.

This term was introduced in 1874 by the german biologist HAECKEL (1834-1919) According to him, the individual construction of any living being retraces, at the successive **stages** of the embryonic development, the basic characteristics of the embryos of the species from which it evolved: In a (too) short synthesis, **ontogeny** repeats phylogeny.

→ **Embryogenesis; Ontogenesis**

2560

PHYSIONICS

→ **Bionics**

2561

PLANET as a SYSTEM¹⁾

A. LOTKA introduced the idea to consider our planet as a **whole**, as a global system (although using a vocabulary of mecanicist style); "The great world engine – in which each of us is a most insignificant little wheel – has its **energy source**, its firebox, so to speak, in the sun" (1956, p.331).

This is more than a mere **metaphor**. LOTKA dedicates a significant part of his "Elements of mathematical biology" to the study of energetic exchanges between the atmosphere, the lithosphere and the hydrosphere and describes, in an explicite way the living beings as a **whole** (biosphere) or a unified system of coupled **transformers of energy**, tending towards its maximal possible use, in connexion with the planet system.

LOTKA has been indeed a precursor of LOVELOCK's GAIA's idea and of PRIGOGINE's **thermodynamics of dissipative systems**.

2562

PLANNING¹⁾

" The act or **process** of deciding in advance what to do" (UNESCO – UNEP, 1983, p.20).

The UNESCO – UNEP "Glossary of environmental educational terms" adds the following complementary definitions: "A dynamic effort to use **decisions** to guide future **actions** and **decisions**. A continuous **process** which identifies, analyzes, decides **goals/ends**, alternatives, **programmes**, and **evaluations** in guiding the future and in coming up with solutions for present and future problems" (Ibid).

The basic postulate for planning is the possibility of **prediction**. However, **prediction** remains still more of an art than a science. Moreover, it becomes now clear that **predictability** is never total and more and more imperfect for **situations** and systems **transformations** more distant in **time**.

Planning also implies **choice**, i.e. the **selection** of preferred **constraints** on the future.

The scope of planning is becoming wider and wider with the ever growing **interactions** of numerous **complex systems**. It has also become divided in more specific areas, as for example tactical and strategic planning.

The need to differentiate **short, median and long-term** planning is also more and more recognized.

In synthesis, planning is an ever wider embracing activity and thus systemic **methods** are in growing need.

2563

PLANNING: A systemic-cybernetic view ¹⁾

Efficient planning requires some conditions which are not frequently respected:

- a **knowledge** as complete as possible of the system or **organization** whose **transformation** is sought, i.e. a good **understanding** of the **interrelations** between **subsystems** and ongoing **processes**
- the **understanding** that **linear** solutions cannot work satisfactorily for long **time** in **complex nonlinear systems**.
- a sufficient **knowledge** of the **environment-system correlations**
- the **understanding** of the **stability** and **metastability** conditions to which **complex systems** are submitted, as well as the possibility of unforeseen (**chaotic**) **behavior**.
- a good estimation of the **limits to forecasting** and of the probability of wider **deviations** with **time**, with, if possible, an **evaluation** of such possible **deviations**.

St. BEER expresses forcefully the following cybernetic view of planning: "Planning should be continuous and adaptive. Societary plans should continuously abort, and be recast, before they give birth to a monster. If this is true, there is no need to base them on the **predictions** that no-one can correctly make in any case, but only on the analysis of an unfolding **situation** in which every **decision** constrains future **variety**. In that statement the unpopular notion of planning is turned on its head, and deserves to become popular again... We can make, rather than prophesy, the future" (1974, p.91).

Of course we would be able to "make" a satisfactory future (i.e. acceptable for everybody) only if we avoid a number of traps, as for example authoritarianism, ideological biases, **underconceptualization**, and even the ignorance of our own ignorance about the deeper reason of an unsatisfactory **situation** that we seek to better.

E. JANTSCH proposed two basic **rules** for purposeful **organization** or planning, corresponding to the above conditions: "1) Make **structures** as flexible as possible, so that it can be changed by emergent **changes** in the

interaction of processes; and 2) identify and enhance evolutionary **processes** of **change**, recognize and respect their self-bounding nature" (1976, p.63).

Shortly, wishful, authoritative and rigid attitudes in planning should be avoided, as well as *unwarranted* simplifications.

This implies however a question mark about *warranted* ones. G. VICKERS stated: "Some simplification there must be, and therewith much exclusion and distortion". We thus need **criteria** for satisfactory simplification as, "The more crudely simplified the **objective** the more efficiently it is likely to be pursued" (1967, p. 65).

However, trading global **fitness** for unilateral **efficiency** becomes more than once a devilish pact, whose future **cost** may be high and bitter, as already proven in many cases.

See: **Approach (The ten commandments of the systemic)**.

2564

PLANNING (Anticipatory) ¹⁾

"A planning **process** which attempts to foresee potential problems and to develop solutions to them before they become real, current problems" (UNESCO - UNEP, 1983, p.20).

Anticipation depends on **predictability**, which is always imperfect, and more so for complex **situations** and systems - whose **complexity** is frequently underestimated (see above and below).

W.D. GROSSMANN and K.E.F. WATT offer the following proposals for a "planning branch unit" in government:

"A. ... (Would) function as a continuous monitor of the institution (i.e. the Government), its activities and its **environment**, looking for... strategic errors... and determining (needed) corrections...

"B. ... foster, facilitate and expedite the free **flow of information** ... (with the possibility that) anyone inside or outside the institution could seek an audience with this unit, to point out... a potential treat they have noticed...

"C. ... (manage) innovative **structural** changes in **organization**, or **activity** within the institution...

"D. ... act as a self-corrective unit which would be constantly asking and following questions... inviting people both inside and outside the institution to offer their views" (1992, p.12).

2565

PLANNING (Generic and General) ¹⁾

J. WARFIELD states that "Planning for isolated entities in (complex) societies is becoming more and more unrealistic, in the face of **interactions** that cut across **domains** once viewed as relatively independent. In recognition of this

situation, the question of how to change planning to make it more responsive to the new **complexities** has become very timely...

"In recognition of the broad nature of the challenge to improve planning so that it can span interdependent **domains**, it is appropriate to work from a comprehensive and fundamental perspective. With such a perspective, the future of planning might be thought to depend on documented research. The research might be thought to require a theoretical component, an empirical component, and an **integration** of the theoretical with the empirical. A further condition might be imposed that rigorous **criteria** would be applied to the **integration** and that quality **control** might be exercised through the continuous **assessment** of any science of **design** that might be proposed as well as to the application of such a science.

"The concept of *generic planning* might be set forth as a way of distinguishing this broader view of planning from the concept of *specific planning* that might be used to describe what has typically gone on in the past. Finally the idea of *general planning* might be taken as the comprehensive name for the **integration** of generic and specific planning to form the ultimate total body concerning all planning" (1991 c, p.92).

WARFIELD's statement can be considered as a kind of general manifest about what systemic planning should try to achieve.

2566

PLANNING (Interactive) ^{2) - 4)}

"A **methodology** for solving an interrelated **set** of problems" (G.A. BRITTON & H. McCALLION, 1994, p.503).

According to these authors, widely inspired by R.L. ACKOFF's "Interactive Planning", the **methodology** includes five interconnected phases:

"**Mess** formulation: an analytical phase that results in a clear **description** of the **problems** and opportunities confronting an **organization**

"**Ends** planning (which) involves developing an idealized **design** and comparing it with the **mess** formulation to identify the gaps that need to be filled by planning

"**Means** planning (during which) alternate ways are invented to achieve the planning gaps identified during **ends** planning

"**Resource** planning (which) involves determining the **resources** that are available, the resources that are required to implement the **means** plan, comparing the **resources** required with the available **resources** to identify the **resource** gap, inventing and evaluating alternative ways to meet the **resource** gap, and selecting an appropriate **resource** plan.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

"Implement **means**: the last phase, to identify the tasks required to implement the **means** plan, to assign these people for execution, and to **design** and establish a **control** system to **monitor** and **control** the execution" (p.504).

"The **purpose** of interactive planning is to enable the **stakeholders** of an **organization** to progress more rapidly toward the ideal of *omni-competence*. The idealized **design** of the **organization** should be more **adaptive** and better at **learning** than the existing **organization**" (Ibid).

ACKOFF insists on three basic needs to enable interactive planning:

- 1) A multidimensional **organization** with three basic ones: **inputs (resources)**; **outputs** (products and services) and market (customers)
- 2) A circular organizational **structure** which "prescribes how the **hierarchical command structure** can operate to facilitate participative **planning** and **decision-making**"
- 3) A responsive **decision** system to "prescribe the essential properties of a stand-alone system to **control** the implementation of **decisions** and how a **set** of these can be interlinked **recursively**" (p.505).

(For very important developments, see reference).

There are of course some question marks, as for example: – Who defines who are the **stakeholders**

- Where and when are the **interactions** of the organization with its **environment** (e.g. impact of new technologies, ecological problems) discussed, if at all ?)
- How and when are the views and proposals submitted to critique, and by whom (What is, for instance, an "idealized" design ? Who defines what is "ideal", for whom, under which **criteria**?)

M.C. JACKSON offers a complementary viewpoint from a different perspective: "Three principles underpin interactive planning... The first is that the **process** of planning is more important than the actual plan produced. It is through involvement in the planning that **stakeholders** come to understand the **organization** and the **role** they can play in it... All those who are affected by planning should be involved in it...

"The second principle is that of continuity. The **values** of **stakeholders** will change over time, and this will necessitate corresponding **changes** in plans. Also unexpected **events** will occur... No plan can predict everything in advance, so plans, under the principle of **continuity**, should be constantly revised...

"The final principle is the **holistic**; we should plan simultaneously and interdependently for as many **parts** and **levels** of the system as possible. This can be split into a principle of **coordination**, which states that units at the same **level** should plan together and at the same time (because it is the **interactions** be-

tween units that give rise to most **problems**), and a principle of **integration**, which insists that units at different **levels** plan simultaneously and together (because decisions at one **level** will usually have **effects** at other **levels** as well" (1992, p.147).

BRITTON suggested integrating interactive planning with BEER's **viable system model**, that could be used for **diagnosis** and **design** purpose. The **methodology** could also be combined with J. WARFIELD's **Generic Design, Generic Planning** and **Interactive Management**, which include techniques to avoid "**underconceptualization**", i. e. narrowness of **perception** and **understanding** of complex **situations** features.

According to WARFIELD the successive planning phases should be:

1. Approach to issue, on base of triggering and generic questions, using **Nominal Group Technique** and **Interpretive Structural Modeling**.
2. **Issue** exploration.
3. **Issue** definition (using the same techniques)
4. **Design** of alternatives (again using the same techniques, with triggering and generic questions)
5. **Choice** of alternative (still in the same way)

This secures that, as much as possible, nothing is taken for granted and that the participants do not remain stuck in uncriticized assumptions.

As a group **process** in which an ideal future of a system is **designed**, interactive planning is a specific application of **participative design**.

J. JOHANNESSEN states: "The basic idea of interactive planning is that the **environment** of the **organization** does not exist as given **objects**, but is created as an integrated **process** from various systems. The **organization** can choose between taking part in this **process** or passively adapting to the **environment**. The first angle of incidence is active and creative. The second one is passive and **adaptive**" (1991, p.46).

According to RAVN, as quoted by JOHANNESSEN: "Interactive planning is a **method** for breaking down mechanistic and bureaucratic social **structures**, and bringing out human and social potential in a new and more refined way".

Interactive planning implies the participation of every interested people or **group**, each of whom can bring into the **process** specific **knowledge**, **models**, **viewpoints** and **methods**.

It is necessarily a dynamic **process**, since it must take in account continuous **change** in the **environment** and also in the personal needs, motives and **information** of the participants.

JOHANNESSEN proposes an interesting use of J. MILLER's **taxonomy of living systems** as base for the construction of a **matrix of interactions** between the different **roles** of the participants within the **organization**. Such a cou-

pling **matrix** is quite useful to discover "who is who" and "who does what", thus producing a most complete view of how **structures** and **processes** are associated to people. Such a knowledge of the **organization** is basic before launching any **process** of interactive planning.

2567

PLANNING (Recursive)¹⁾ – 2)

The **process** of submitting any plan to frequent revisions.

There are at least three reasons to admit the necessity of frequently revising a plan on the march:

- Any plan is based on a simplified view of reality, based on **criteria** that may turn doubtful or unsatisfactory with **time**.
- In complex **situations** and systems, the multiplicity of **initial conditions** introduces the possibility of **deterministic chaos**, which implies that the system may not be as manageable as initially believed, or that it should be managed differently, after better **evaluation** of dominant and secondary conditions.
- The initial or subsequent results of steps already taken should be evaluated, in order to avoid surprising possible side-effects and **deviations**.

2568

PLAUSIBILITY³⁾

"...a speaker's degree of belief or confidence in a statement, given the available evidence" (W.H. JEFFERYS & J.O. BERGER, 1992, p.66)

Plausibility is a subjective **evaluation**, not a statistical one. When this latter cannot be obtained because no experimental trials are possible, the **Bayesian** concept of **probability** is useful, as for example in **forecasting** or for **evaluation** of non-verifiable hypothesis.

2569

PLAYER (von NEUMANN's): a critical view²⁾

G. BATESON writes: "The 'player' of a von Neumannian **game** is a mathematical fiction, comparable to the Euclidian straight line in geometry or the Newtonian particle in physics. By definition, the player is capable of all computations necessary to solve whatever problems the **events** of the **game** may present; he is incapable of not performing these computations whenever they are appropriate; he always obeys the findings of his computations. Such a player receives **information** from the **events** of the **game** and acts appropriately upon that **information**...

"... in von NEUMANN's formal definition of a 'game' all problems which the **game** may present are conceived as computable, i.e., while the **game** may contain problems and **information** of many different **logical types**, the **hierarchy** of these types is strictly finite" (1973, p.255).

Most important of all "The player in incapable of 'error'... , he is by definition incapable of '**learning by trial and error**'" (p.256), which shows him (it!) as a perfectly **programed automata** and thus a poor **model** of very complex real systems (including artificial ones like neural computers, of which it has been said that they are "very difficult to program").

2570

PLURALISM (Methodological)

→ Methodological Pluralism

2571

PLURIPOTENCE¹⁾³⁾

The original term used by the german biologist H. DRIESCH to name the embryonic property also known (in a more general acceptance) "**equipotentiality**"

2572

POIESIS¹⁾²⁾³⁾

The **production** and **reproduction** of internal **structures** within a system.

This is properly the whole activity of the system as considered by the **autopoietic theory** of MATURANA and VARELA.

The internal structures are either biological or neurological. At the human **level** the **self-reproducing** body is the sine qua non condition for the creation of **information**, i.e. the well-connected and evolving **frames of references**.

2573

POINCARÉ Section⁵⁾

A **method** "of reducing the study of **continuous time** systems (**flows**) to the study of an associated **discrete** time system (**map**)" (S. WIGGINS, 1988, p.67).

J. GLEICK explains this mathematical technique as follows: "The technique reduces a three-dimensional picture to two dimensions. Each time the **trajectory** passes through a plane, it marks a point, and gradually a minutely detailed **pattern** emerges" (1987, p.143).

The same technique may be applied to more complex systems, i.e., with a higher number of initial independent conditions.

WIGGINS emphasizes: "In lower dimensional problems (say dimension <4) numerically computed POINCARÉ maps provide an insightful and striking display of the global **dynamics** of a system" (p.67).

In this way, it becomes possible to gather an understandable picture of any **attractor**, be it common or strange. POINCARÉ's method is also related to the **ergodic** relation.

P. BERGÉ, Y. POMEAU and Ch. VIDAL state: "... POINCARÉ's section leads to the replacement of the **description** of some **evolution continuous in time** by an application at **discrete intervals of time**."

Moreover: "...POINCARÉ's section presents the same type of **topological** properties as the **flow** of which it is born, because of its mode of construction... If the **flow** passes an **attractor**, the structural characteristics of the same will be found in the POINCARÉ section" (1984, p.67).

Thus, this **method** makes quite easier the study of the different types of **stabilities** and **instabilities**.

2574

POISSON DISTRIBUTION²⁾

A sharply single peaked probabilities distribution **function**, which is a good **description** of the results of repeated **random** experiments of some kind.

Such distribution is observed only if the successive experiences are not **correlated** or at least not strongly correlated, i.e. cannot notably influence each other.

Very significantly, in complex systems, in I. PRIGOGINE's words: "Only **fluctuations** of sufficiently small dimensions obey POISSON statistics. This is a very important result because it implies that, conversely, only **fluctuations** of a sufficient extension can attain enough importance to compromise the **stability** of the **macroscopic state** considered" (1976, p.117).

2575

POLARIZATION¹⁾²⁾⁴⁾⁵⁾

"A concentration of **groups**, forces or interests, about two conflicting or contrasting positions" (Am. Her.Dict., p. 1014)

Polarization is a very general **phenomenon** from physics to social sciences (in this case in a more or less **metaphorical** sense)

It corresponds to the presence of two different **attractors** whose respective **fields** interact.

2576

POLICY making in systemic terms^{1) - 4)}

"A set of principles laid out for the purpose of **regulating** simultaneously and in a viable **mode** a multitude of interacting **relationships** pertaining to many qualities and dimensions of human life" (E. JANTSCH, 1975, p.6).

This definition by JANTSCH puts in a crude light the shortcomings of what is generally meant by "policy" (and politics!). As to JANTSCH "viable **mode**", let us observe that defining this is not easy and implies a very

deep **knowledge** of the various and variable ways systems are working. Such **knowledge** is moreover, by necessity, forever incomplete. **Regulations** should thus, as expressed by JANTSCH, be evolutive. This supposes an ever-more conscious and not contradictory **design process**.

Moreover the **concept** of **regulation** already implies the presupposition that the considered system is **homeostatic**, i.e. maintaining the permanence of its **structural** and **functional** characteristics. It is now well known that many **complex systems** – and mostly human ones – are **dissipative**, **chaotic** and **emergent**, and thus cannot be stabilized until they reach a new **dynamic equilibrium** condition. Unfortunately, **deciders** are generally unaware of this and pay no heed to it.

J. WARFIELD studies policy making in an extensive way (1988, p.89-118). His subjects of interest are:

- A census and critical appraisal on traditional ways of policy making;
- The nature of policy making;
- The **stakeholders** in policy;
- Policy **evaluation**;
- **Methods** for studying policy making;
- **Constraints** on policy making;
- The concept of metapolicy, i.e. "policy about how to make policy" (Quoted from Y. DROR)

The subject has also been interestingly explored by P.M. ALLEN et al. (1984) and by W.D. GROSSMANN and K.E.F. WATT (1992).

2577

POLISH SYSTEMS SOCIETY¹⁾

This national systems society has been created in 1995 by a group of polish systemists at the Technical University of Wroclaw, under the leadership of Prof. Mieczyslaw BAZEWCZ.

The objectives of the PSS include "inspiration, support and providing of systems research and inquiry, formation and development of systems education and culture, creation and development of systems methodology with an interdisciplinary scope, as well as the popularization of a wide-conceived systems knowledge".

This programme is exposed in details in the first issue of the Journal "Systems" (Journal of Transdisciplinary Systems Sciences) whose publication was also started in 1996.

The Polish Systems Society is affiliated to the International Federation of Systems Research. It established a network of collaborators in quite a number of countries in Europe, North and South America and East Asia.

The editorial office of the journal is: Oficyna Wydawnicza Politechniki Wroclawskiej, 50-370 Wroclaw, Wybrzeze Wyspianskiego 27, Poland

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

2578

POLITICS⁴⁾

The government of human **organizations**.

From a systemic viewpoint, it is important to understand *how* **organizations** do manage to sustain themselves, how they define **goals** and pursue them. This however also implies a study of how some individuals or **groups** become dominant and more or less succeed in managing and controlling an **organization**.

As to the first aspect, the need for **critical subsystems** – twenty of them, according to J.G. MILLER – corresponds to the various **processes** needed to secure the **survival** of the system within its **environment**. Each **subsystem** must have definite capabilities, act in a coherent way and coordinate its **action** with other **subsystems**. It must thus obtain specific **inputs** of **matter**, **energy** and/or **information**, be able to use them and to produce some **outputs**, either products required by the system itself or by its **environment** (including **co-systems**), or unwanted subproducts that must be somehow eliminated in a non dangerous way. Politics in this aspect, is a matter of securing these conditions by appropriate, i.e. non self-defeating, **regulations** and **controls**.

The study of the ways some individuals or **groups** succeed in obtaining and maintaining the “**control** of the **controls**” and eventually loose it, as well as the **relations** they maintain with other **groups** and the way power is traded and transmitted through **time**, should form the core of the systemic-cybernetic study of politics.

Many systemic-cybernetic **concepts** could be used: **theory of communication** (including **semantic coding**, **channels capacity**, **noise**, use of **redundancy**); **theory of regulation** and **control** at multiple **hierarchical levels**; **hierarchical organization**; concept of **order parameters**, **slaving principle**; **values** and **norms**; **mindscapes**; **organizational closure**; **stigmery**; etc...

This is still largely an unexplored field, notwithstanding the efforts of K. DEUTSCH (1961, etc.), D. EASTON (1965a, b), W. BUCKLEY (1968) and some few others.

2579

POLYCENTRISM^{2/4)}

A form of extended lax **organization** connecting various local ordering centers that coexist in a common global **environment**

The present coexistence of various **socio-cultural systems** within the global **man-plan-et system** in the making could be an example

→ **Graph**; **Hexagonal space filling**; **Multi-stat**; **Node**; **Structure (Dissipative)**

2580

POLYETHISM^{4) – 5)}

The presence of different classes of ethological **roles** in social insects.

This term has been introduced by J. WEIR in 1958. According to E.O. WILSON, polyethism is one of the main factor explaining the considerable success of social insects (1971).

In social insects, it leads to **polymorphism** (sometimes reversible).

Polyethism is still more obvious and important in human societies. It may be interpreted as a kind of collective internalization of **adaptation** to **environmental** necessities.

It is doubtless a condition for **socialization**, as it connects the need for social **variety** with individual differentiation.

B. CORBARA and A. DROGOU observe that polyethism is more or less correlated to age, and can be considered as an **emerging phenomenon** (1992, p.832-834). Polyethism is more differentiated in more complex societies.

2581

POLYFUNCTIONALITY^{1) – 2)}

The characteristic of any **element** included in different **structures**.

G.S. SCUR uses the **concept** in linguistics, where it could be more specifically called “**polysemy**” (1965, p.98).

It seems however more general. A person, for example, is generally polyfunctional, as a worker, as a parent, as a consumer, as a hobbyist, etc...

Polyfunctionality can obviously be a cause of tension within **organizations**, that must harmonize and optimize the many times divergent **objectives** of their members.

It also can be a serious problem for the individual, who must reconcile into a global system of **behavior**, **objectives** that may be quite divergent, if not downright contradictory.

2582

POLYMORPHISM^{1) – 5)}

The occurrence of different basic characters, forms or types in a **population**.

The concept comes from **population** genetics, but has a more general scope.

Polymorphism may be transient when the **environment** acts as a **filter** and eliminates some variants. It may be permanent if some **variety** is necessary for a better global **adaptation** of the **population** to a fluctuating **environment**.

According to R. LEVINS: “Polymorphism contributes to the **fitness** in two distinct ways. If the **environment heterogeneity** is large compared to the **tolerance** of the individual (if the **environment** consists of several discrete **niches**, in which different **phenotypes** are optimal, or if it is distributed bimodally about **modes** which are sufficiently far apart com-

pared to the **tolerance**), a certain **phenotypic heterogeneity** is advantageous as a ‘mixed strategy’ in conditions of temporal **fluctuations**.

“Regardless of whether this first type of polymorphism is desirable, genetic **heterogeneity** is necessary for any **response** to **selection**. The **response** to **selection** is advantageous if the **environment** is sufficiently strongly auto-correlated” (1961, p.38).

Polymorphism guarantees that at least some individuals in a population will adapt even to strong environmental variations. It corresponds to ASHBY’s **variety**.

The suppression of polymorphism as for example in excessive **selection** in plants, leading to mono-cultivation, may be risky. Inversely, the existence of polymorphism, for instance in a population of pests, explains the progressive appearance of varieties resistant to chemicals.

Conditions analogous to polymorphism also seem to exist in animal **behavior** and in human social and cultural life.

→ **Diversity**

2583

POLYSEMY^{1) – 3)}

The multiplicity of shades of **meaning** that any word may take within the **semantic space** of a **language**.

Words, just like electrons, atoms, molecules, **cells** and individuals, acquire a different **positional value** within different **contexts**. This is a very important feature, which relativizes and at the same time enhances the value of **languages** in conveying **meanings**.

Unfortunately, polysemy is frequently used to distort **meanings** and confuse **receivers**. Many **senders** are even themselves unaware of the dubious **meanings** they do transmit.

Polysemy plays also an important role in the **evolution** of **languages** because it favours *progressive* reductions, extensions and shifts of **meanings**.

2584

POLYSEMY IN MATHEMATICS

→ **Mathematics (Polysemy in)**

2585

POPULATION¹⁾

1) The global **set** of individuals or **elements** of a same **class**, i.e. sharing defined characteristics.

A population is generally confined within a limited **space**, possibly with very different local **densities**.

While belonging to the same **class**, no individual is absolutely identical with any other: populations are generally **polymorphic**, within **limits**.

A population is not only **synchronic**, but also **diachronic** since the number of members may increase or decrease with **time**, as well as their repartition and global or local **densities**.

Populations correspond to a special type of systems, in which every element is directly and dominantly interconnected with the **environment** and only loosely and intermittently with other members of the population (see "**Scattered system**"). This type of systems does not generally possess clearly identifiable **sub-systems**.

2) "An **aggregate** of individuals conforming to a common definition, to which individuals are added (born) and subtracted (die) and in which the age of the individual is a relevant and identifiable **variable**" (K. BOULDING, 1956, p.13)

BOULDING explains: "Birth" occurs when an item begins to conform to the definition which encloses the **aggregation**, and "death" when the item ceases to conform to the definition. A definition may be thought of as closed fence: everything inside the fence belongs to the defined population; birth consists in crossing the fence into the enclosure; death in crossing the fence out of the enclosure. The population concept thus defined is a perfectly general one, and applies not only to human or animal populations, but to populations of automobiles, poems, stars, dollars, ideas, or anything that is capable of definition" (1956, p.67).

In any system that can be described as a population, internal and external **interactions** can be considered in terms of **competition**, **complementarity**, **parasitism** or **symbiosis** "whether the species consist of animals, commodities, social classes or molecules" (ibid, p.13).

3) A generalized and more abstract definition of population is given by T.A. and W. MILLINGTON: "The whole **set** of items which have a common characteristic, which is subject of some sampling in the **process** of statistical analysis" (1971, p.182).

Along this line, populations can be sampled, i.e. an appropriate (and frequently numerically quite limited) **subset** can be studied for some specific characteristics, in view to obtain generalizations by the use of convenient statistical **methods**.

Samples are however referred to a specific moment in **time**. As a result, any dynamic inquiry needs various successive samplings to study temporal **change** affecting the population.

2586

POPULATION EXPLOSIONS ¹⁾

Populations explosions are a result of a unilateral or strongly dominant **positive feedback**, which triggers a **runaway event**. This **process** normally ends in a crash.

Runaways happen when the supply of **energy** or aliments is growing in an unlimited fashion, until some critical **threshold** is crossed.

It can even happen in a more subtle way, as shown by the following experiment, described by L.B. SLOBODKIN: "If a population of green hydra is given a diet of water fleas the hydra proceed with their normal response to population **growth** and become smaller as individuals become more numerous. They become so small, in fact, that they are unable to eat the waterfleas at all and the entire population dies of starvation" (1968, p.153).

In short, the **positive feedback** tends to finally trigger a negative one, which may appear under the guise of starvation, a pandemy, a **process** of biological or **behavioral** (as for instance in lemmings) self-destruction.

One may wonder about the potential lessons for mankind in its present **process** of population explosion.

2587

POPULATION (Meta)

→ **Metapopulation**

2588

POPULATIONS (Stability of mixed) ¹⁾

Heterogeneous populations of a same species, or numerous different species within an ecological system are more stable than **homogeneous** ones.

R. MARGALEF states: "The greater the number of avenues by which **energy** may flow through a **complex system**, the stabler it is" and "... a community exhibiting great stability... is comparable to a system easily convertible within a series of equivalent systems" (1958, p.61).

MARGALEF insists on the importance of "high indices of diversity" – an idea akin to ASHBY's **variety** – and gives a number of examples in **ecosystems**.

However, the **concept** seems quite more general, as it could be applied to any kind of **networks**, as for example neural or social ones.

The number of avenues through which **energy** may flow is also reminiscent of BENARD's and PRIGOGINE's **dissipative structures**, as well as LOTKA's **model of the world engine**.

At least two different **effects** can affect the **stability** of a population:

- Over exploitation- as in the case of hunting or fishing for example, can lead to an excessive reduction of some specific population. In such cases, other species can invade the **niche** left more or less vacant and the species cannot anymore recuperate, or even maintain itself. This may be caused by decreasing genetic **variety** or by an excessive rarefaction of individuals.

- Some strong **perturbation** in the **environment**- as for example a destructive hurricane-may have a similar **effect** by damaging the **habitat** of the species, either for some more or less extended **period**, or definitively. The subject is now considered in **ecology** through **patch-dynamics**.

2589

POSITION EFFECT

See hereafter **Positional Value**

2590

POSITIONAL VALUE ^{1) - 2)}

The value of an **element** in a system as related to its place in a global **structure**.

Back to 1941, A. ANGYAL stated that: "The members of a system... do not become constituents of the system by means of their immanent qualities, but by means of their **distribution** or arrangement within the system. The **object** does not participate in the system by an inherent quality, but by its *positional value in the system*" (1969, p.20).

While fundamental, this concept should also be put into perspective: To become a **part** of a certain system, any **element** must be endowed with some intrinsic characteristics that makes it compatible with the system.

It is the case for example for the immune **compatibility** of a **cell**, or the professional, linguistic or cultural **compatibility** of an individual in an **organization**.

Moreover, the **element**, whatever its position, must be activated through a **morphogenetic** and **autopoietic differentiation process**, triggered by some few original **elements**.

→ **Autogenetic systems precursors and Zero system** (V. CSANYI).

2591

POSITIVISM ³⁾

"The belief that the only qualities of systems which are real or meaningful are those which can be directly measured" (R. ROSEN, 1979, p.175).

This is R. ROSEN's systemic definition of positivism, that he comments in the following way: "Invariably such a belief is coupled with an extremely narrow view as to what in fact constitutes a **measurement** or **observation**, and leads inexorably to an assertion that whatever falls outside this narrow framework does not exist. Worst of all, an exclusively empirical approach gives rise to an utterly false **dichotomy** between "experiment" and "theory", which has done boundless mischief in the world..." (ibid).

¹⁾general information

²⁾methodology or model

³⁾epistemology, ontology and semantics

⁴⁾human sciences

⁵⁾discipline oriented

2592

POSITIVISM (Neurological)³

A theory about the ways world, **brain** and mind are homologously linked.

This interesting **epistemological** view has been introduced by L. R. VANDERVERT (1988, p.313-21)

"Neurological positivism asserts that nervous systems *project* their order onto the **environment** to extract **invariance**. This neurological-level projective **process** is father (**homologically** speaking) to all knowing... and to all **cognitive-level** projection which is a part of the literature of personality psychology. **Knowledge** is a **category** of evolving **invariance** which arises as the result of the projection of the neurological **order**" (p.317).

VANDERVERT inspired himself from LASZLO's **information flow loop** "which include the following:

"1. variant **environment**

"2. **perception input**

"3. **control coding (or coupling)** between **input** and **output** (in neurological positivism this is the neurological **order**)

"4. **output (behavior)**

"This **loop** accomplishes two things. First, it maintains invariant **steady states** in the nervous system (or in **cognition**) through **negative feedback**. Second, it **self-organizes** or adapts the system to the vagaries of the **environment** through projected or projective **positive feedback processes**" (Ibid).

VANDERVERT's views should be compared with J.J. GIBSON's **ecological perception**, BATESON's **ecology of mind**, von FOERSTER's **cybernetics of "observing systems"**, with MATURANA and VARELA's **recursivity and organizational closure** and with M. EIGEN's **hypercycle**.

2593

POSITIVIST POSITION

→ **Phenomenological position**

2594

POSITIVIST STANCE³

"A philosophical position characterized by a readiness to concede primacy to the given world as known through experimental evidence" (R. RODRIGUEZ ULLOA, Glossary, 1999)

The positivist stance dominates all classical physical sciences and also in part biology and its specialized disciplines.

It should anyhow not be forgotten that:

- Our experimental evidence is necessarily filtered by our perceptive system, itself coordinated by our **nervous system**.
- The experiences that we register or perform are conditioned by the previous education of our **perceptions** which thus become "tainted" (M. MERLEAU PONTY, 1945)

- Any scientific experiment is pre-oriented by some theoretical views that are supposed to be submitted to **confirmation** or **refutation** (POPPER)

2595

POST-CYBERNETICS GROUP in Tokyo¹⁾

This group has been created in 1992 in Tokyo by Makiko OKUYAMA, of the Ohmiya Child Health Center (2-24-1, Toro-Cho, Ohmiya-Shi, Japan 336)

It is an **interdisciplinary** group whose members come from "**management science**, **information science**, physiology, public health and psychiatry".

M. Okuyama states: "the name" post-cybernetics was used because the word "cybernetics" strongly reminds people of mechanical and engineering **feedback** systems and, besides we wanted to pursue the new meta-disciplinary **concept**, and not just to be limited to the conservative cybernetics".

More members have joined the group. "Their specialities are **artificial intelligence**, engineering, **cognitive science**, **sociology**, accounting, marketing, and so on."

The group has a monthly conversation "which includes a lecture and discussion."

The above information has been published in Cybernetics and Human Knowing, 2(3), 1994

The present situation of this Group is unknown to this editor.

2596

POWER LAWS²⁾

Similar **rules of energy** use that operate at various **levels** in a system.

Power laws occur when the average **frequency** of an **event** of a given **size** is inversely proportional to some power of its **size**. For example, small earthquakes are quite **frequent**, but much less destructive than the strong ones, which in turn are quite **less frequent**.

Systems near **critical states** seem governed by such **optimization rules** (or power laws) which minimize their expenditures of **energy**.

As a consequence, according to I. RODRIGUEZ ITURBIDE et al (in P. YAM, 1994, p.17): "Rather than emerging from **events** happening nearby or taking place immediately before, **critical catastrophes** may occur because of a global, **long term mechanism**. Specifically, the systems may be minimizing the amount of **energy** they expend in maintaining themselves, thereby optimizing the way in which they develop".

The authors created a mathematical **model** whose statistical properties are exactly the same as those of a drainage **network**, in which "the length of the stream **channels** and the distribution of **branches**, and of the **energy** at any point, all obey these (power) laws. It seems

also possible that in earthquakes **models**, tectonic plates may be organizing themselves locally so as to minimize **stress** for the entire system".

The same **model** could explain how "trees are optimizing their leaf distribution to take advantage of the light they receive".

YAM adds: "The finding raises the question of whether all **self-organized critical systems** evolve through some global principle of **energy minimization**". It also poses interesting question marks about the ways of **interactions** between particles, **elements** or **agents** which are not connected in any known functional way. We obviously need not only a **model** of global **action**, but also one of local and possibly non-local **action** in connection with the global one.

This could lead to a clearer interpretation and understanding of **holographic order** and, generally, of **implicate order** in BOHM's terms and even possibly make sense of R. SHEL-DRAKE's **morphic fields**.

Power laws seem also related to the **fractal** character of many systems. They could offer interesting insights in relation to social **organization** and quiet or violent **change**.

A connection between power laws and so called "**small worlds**" is also probable; the many frequent small connecting steps among nearby **elements** are somehow opposed to unfrequent big leaps between distant **hubs** in a **network**.

This can be observed for instance as two different ways of **propagation in epidemics**

Power laws seem also to explain some typical relations in **ecosystems** (A. FROOD, 2001, P. 30-33)

It could be said that power laws and fractalization are the two faces of the same coin.

This is also obvious in the case of WEIERSTRASS **renormalization group transformation**

→ **Self-similarity in the Weierstrass function**

2597

POWER PRINCIPLE (Maximum)^{2) - 4)}

"Natural systems tend to operate at that **efficiency** which produces a maximum power output. This **efficiency** is always less than the maximum **efficiency**" (H.T. ODUM and R.C. PINKERTON, 1955, p.331-343).

J. MILLER comments: "(Following ODUM) a major **design** principle of natural systems is **feedback** from **storage** to **energy** inflow pathways. This stimulates energetic inflow and **functions** as reward. In this way, **processes** that are doing useful work are reinforced. Such **feedback designs** are **autocatalytic**. They maximize power, *consequently generating more entropy*. **Autocatalytic processes** depend upon sufficient concentration of potential **energy** - **energy** available for doing work. If the **energy** source is weak, the system minimizes **energy flow** and **entropy** generation. The max-

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

imum power principle suggest that natural **selection** operates to select systems **designs** that maximize power. Systems compete for available **energy**.

"Systems of this sort develop **hierarchies** with successive **transformations of energy** in which **energy** increases in "quality" as units increase in **size**" (1986, p.78).

ODUM discovered the principle studying **ecosystems**. It fits, however, nicely **human systems** throughout the whole technological **evolution** of mankind. The principle looks like a good explanation for the general **phenomenon of evolutive acceleration** (F. MEYER, 1954).

2598

PRACTICE and/or PRAXIS? ²⁾³⁾⁴⁾

W. Mc WHINNEY observes that these two **concepts** are quite different from each other.

He states: "Practice focuses on a habitual and systematic **process** of doing. I further stipulate that a practice follows an implicit set of **rules or theories**..." And "Practice ...follows a **program**" (1997, p. 80)

As to "Praxis", it "is the study and practices of attaining **goals**. It focuses on the goal without the confines of a limiting set of rules"...and "Praxis is a way of working beyond theory and practice, getting results beyond those available within a single **domain** of work" (Ibid).

Practice would determine for example the correct way to use a screwdriver, while praxis would define the choice of a screwdriver among various ones or even some other tool in some specific **situation**.

While this may seem at first sight somewhat far fetched, McWinney makes his point very clearly in his paper.

2599

PRACTICE in the social systems sciences ⁴⁾

R.L. ACKOFF, in a very realistic way, developed the following views about practice.

"By a **social system**, I mean a system in which people play the most critical **role**. This does not include telephone and water-supply systems, but it does include telephone companies and water-supply agencies.

"By practice I mean work for clients who have the authority to change the system worked on in ways specified by that application. I do not mean work on **problems**, however real they may be, without the direct involvement of those who are responsible for doing something about them and those who are directly affected by them – the **stakeholders** in the **problem's** solutions.

"By a theory of practice I mean a **set** of definitions and propositions from which testable hypotheses about the effectiveness of practice can be deduced. By effective practice I mean improvement in the **performance** of client or-

ganizations from the point of view of at least some of the **organizations' stakeholders**, and the absence of deterioration of that **performance** from the point of view of any.

"By a practitioner of the **social systems science** I do not mean one who, confronted by an **organization's mess**, collects symptoms, diagnoses, and prescribes as a doctor does with a patient. I mean one who, through encouragement and facilitation, enables others to deal with their **messes** more effectively than they can without his help...

"For me, practice is first and foremost an educational **process**, not only for those with whom we work, but for practitioners as well. If they don't learn through their work with others, they are not practicing, but consulting, sharing what they already know. Put in another way: the **objective** of practice is to increase the **development** of the client system, its **stakeholders**, and the practitioners engaged in that effort" (1988, p.241).

These views could deeply transform the ways of the three different "classical" types of practitioners described by ACKOFF:

"1) **Input-oriented practitioners**, ones who define themselves by the tools, techniques and **methods** they employ in solving **problems** – for ex., applied mathematicians, computer programmers, accountants and radiologists;

"2) **Output-oriented practitioners**, ones who define themselves by their product, the kind of **problems** they solve – for ex. those who develop incentive, compensation or **management information systems**, "head hunters" and cardiologists;

"3) **User-oriented practitioners**, who define themselves by the class of users they try to serve – for ex. general contractors and practitioners of general medicine" (p.246).

2600

PRACTICE (THEORY and) ^{1) – 3)}

R.L. ACKOFF asks : "Can one practice without theory and theorize without practice?" and answers as follows:

"Of course one can do both, but theory without practice (application) is **form** without **content**, and practice without theory is **content** without **form**. Practitioners should bring to their practice both a theory of practice and theories to be used *in practice* (**contextual theories**) A practitioner who has no theory of practice flounders when confronted with a new **situation**, at best muddles through. A practitioner who has no **contextual theories** is merely a **change agent** who can provide no assurance of inducing **development**" (1988, p 245).

2601

PRAGMATICS ³⁾

"The theory of the **relations** between the **signs** and their users"(D. GERNERT, 2000a) p. 156)

According to GERNERT: "From the very beginning, **pragmatic information** has been characterized by the "property to change the receiving system"(quoted from KORNWACHS and von LUCADOU, 1982) or more formally, by the property to alter **structure** and/or **behavior** of the receiving system"

He adds: "Two constituents of pragmatic information are termed "novelty" and "**confirmation**". A **message** only repeating well known stuff contains no novelty and hence no pragmatic information (here again, a comparison with syntactic **information** is worthwhile). On the other hand, a **message** in an unknown foreign **language** can bring about no impact upon a receiver -it carries no "confirmation", that is, no relation to the receiver's state of **knowledge**, predisposition, or information requirement. Pragmatic information requires both novelty and a concrete relation to the receiver's predisposition: the amount of pragmatic information will rise as novelty and/or confirmation increase"(Ibid p. 159-60)

→ **Meaning; Meaningless; Semantics (General); Semiology; Semiotics**

2602

PRAGMATISM: A systemic view ³⁾

According to the American Heritage Dictionary, philosophical pragmatism is: "The theory developed by Ch.S. PEIRCE and W. JAMES that the **meaning** of a proposition or course of action lies in its observable consequences, and that the sum of these consequences constitutes its **meaning**".

J. WARFIELD enumerates the following components of PEIRCE's pragmatism (pers.comm.):

"- **Inference** gradually leads into **habit**
"- Authority is one of the four ways of fixing belief

"- Once belief is fixed by authority, it is sustained by tenacity

"- If authority and tenacity are not the origins of belief, then two other possibilities remain: metaphysics and science

"- Metaphysics fixes belief through speculative reasoning

"- Science fixes belief through cyclic means involving investigations of questions

"- Questions are superior to assertive hypotheses as bases for scientific study.

Moreover, "Every question involves contextual implication" which "In the first instance refers to:

a) the linguistic demand places on the recipient of the question

b) the hypotheses that underlie the question" (This is obviously where the systemic view enters).

"In the second instance contextual implication refers to

a) the (implied) questions to which those hypotheses are possible answers, and

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

b) The contextual implication of the implied questions

c) the hypotheses underlying those questions... "and so on until a possible point is reached where there is no contextual implication. If such a point is reached it is in the axiomatic domain" (Ibid)

This is a typical **recursive process** which should not leave any **epistemological** stone unturned.

C.W. CHURCHMAN and R.L. ACKOFF gave a systemic interpretation of pragmatism as follows:

"a) From criticism it borrows the notion of the interplay of **observation** and concepts, though it gives neither an autonomy or fixed character.

"b) From Hegelianism it incorporates the rejection of the "certainty" of immediate sense **data**, but it denies the "primacy" of any absolute.

"c) From Hegelianism it incorporates the notion of **process** as critical to **inquiry**, but negates Hegelian idealism and metaphysics.

"d) From 19th century developments in formal and physical sciences it incorporates the rejection of the certainty of scientific laws (as expressed, for example by POINCARÉ (1857-1912), and recognizes that the *a priori*, through necessary, is selected, not given.

"e) From a development characterized by the French philosopher RENOUVIER (1815 - 1903) it accepts the notion that scientific interests cannot be separated from other human interests (e.g. morals), and that **truth** is a **function** of usefulness.

"f) From 19th century developments in psychology and British social philosophy it accepts an orientation toward **objectives**, **goals**, aims and desires.

"g) Finally, from KANT, it eventually incorporates the notion of "ideal pursuit" as a measure of progress, but unlike KANT, it seeks to treat ideals naturalistically (1950, p.194).

While the influence of "ideal pursuit" is obvious in anything C.W. CHURCHMAN has done, and in the pragmatic stand in the whole of R.L. ACKOFF's work, the systemic view is only latent in their interpretation of pragmatism, in the form of a somewhat vaguely enunciated concern for global **interconnections** between human concerns.

C.S. PEIRCE's pragmatism is possibly reflected in a stronger and truer systemic way in J.G. WARFIELD's **Generic Design Science, Interpretive Structural Modeling and Nominal Group Technique**.

2603

PRAXIOLOGY¹⁾

The science of the conditions of **efficiency** of all **action** (T. KOTARBINSKI, 1995, p.32).

KOTARBINSKI seems to have been the initiator of the praxiological studies (1965). "The Learned Society of Praxiology" of Poland (Nowy Swiat Str. 72 - 00-330 Warsaw) is now the center of these studies and publishes an "International Annual of Practical Philosophy and Methodology" whose Editor-in-chief is W. GASPARSKI

(See A. COLLEN & W. GASPARSKI, 1995)

2604

PRAXIS

→ **Practice and/or Praxis**

2605

PREADAPTATION¹⁾

The condition of a system whose already acquired characteristics makes it fit to respond satisfactorily to new future conditions.

In a narrow sense, the concept is nearly tautological, i.e. when future conditions are a normal result of the present ones, as for example in the progress of a biochemical reaction (ROSEN, 1991a, p.544).

In a broader sense, a system endowed with much **variety** may be preadapted to some **variations** in its **environment** that are of a completely new type.

The concept remains however fuzzy: Can it be said that the anopheles mosquitoes that became resistant to various insecticides were "preadapted", or possibly possessed a "potential for adaptation", whatever this may mean?

M. BUNGE introduces the curious concept of premaladaptation (1979, p.104): In this case the mosquitoes killed by insecticides would have been "premaladapted" (also somehow a tautology!)

→ **Predictor**

2606

PRECAUTIONARY PRINCIPLE

→ **Caution principle**

2607

PREDATOR (Man as a)

→ **Man as a predator**

2608

PREDATORY BEHAVIOR¹⁾²⁾⁵⁾

The **behavior** of a **living organism** that obtains the **inputs** it needs by capturing other organisms or by plundering some other environmental **resource**.

Practically all living beings eat some other living beings and are eaten by other in turn. This is one of the most basic facts of life and **ecology**.

The dynamics of the variable **interrelations** between predators and prey have been researched mainly during the 20th C. by ecologists, demographers and mathematicians.

Two very important contributors have been V. VOLTERRA (1931) and A. LOTKA (1956)

Since the 1970's the subject has been widely reconsidered because some irregularities in the evolving and interrelated **populations** sequences of preys and predators could not be clearly explained. R. MAY has been possibly the main innovator in the field, by showing that "simple mathematical **models**" can produce "very complicated **dynamics**" 1976, 1977, 1987)

In fact, these now models have widely contributed to the elaboration of **chaos** theory, and, in turn, have benefit from other developments in the same theory

→ **Dynamics (chaotic), Growth, Logistic equation**

2609

PREDICTABILITY^{1) - 2)}

The more or less relative possibility to make **forecasts** about some **process** or systems **behavior**

W.R. ASHBY stated: "One common idea, for instance is that the **brain** can predict the future. The idea certainly has a superficial **plausibility**, but is fundamentally wrong. WIENER put the truth succinctly when he said that to predict the future is to carry out an **operation** on the past. If the past shows repetitions, and if the future sustains the regularity, then the **brain** will score a hit when the future arrives. But the **process** is wholly based on past **events** and on the degree to which the real world has consistent regularities. Let the world produces something really new, and the **brain**, human or other, is helpless. What happened, for instance, to those who worked with X-rays in 1905 ? They burned themselves horribly. The **brain** cannot deal effectively with the really new: it must wait until the new has had **time** to go adequately in the past. All wisdom is after the **event**. What we expect of mechanical **brains** must be based on this fact, if our expectation is to be realistic" (1963, p.207-208).

According to F. HEYLIGHEN: "**Processes** that are predictable, but not reversible are characterized by the fact that **distinctions cannot be created** (i.e. distinct effects always result from distinct causes),... **but can be destroyed** (i.e. distinct causes can have equal effects)" (1989, p.2369)

"**Processes** that are reversible but not predictable are characterized by the fact that **distinctions cannot be destroyed** (i.e. distinct causes always lead to distinct effects), but can be created (i.e. equal causes can have distinct effects) (Ibid.).

This abstract statement mirrors the fact that predictability is always *practically* limited. Total **reversibility** is impossible in the real world, which always allows for some measure of unpredictability. But the existence of **giant fluctuations**, with the possibility of **bifurcation** and even, in some cases, **emergence** of higher **levels of complexity** in **processes** and systems, nearly completely impedes precise predictability.

F. HEYLIGHEN adds: "From the point of view of predictability,... the microscopic **causality** principle is useless or trivial, since it ignores all repetitions of **processes** or experiments. Predictability only exists on a **macroscopic level**, where **microscopic** differences between non identical, individual **phenomena** are ignored, to determine the macroscopically meaningful **distinctions** between (infinite) **classes** of **phenomena**" (p.378).

HEYLIGHEN proceeds, giving the following example: "It is a classic result that **phenomena** that are completely unpredictable at the **microscopic level** may be modelled macroscopically by **deterministic** theories. For example, statistical mechanics shows how the **random** collisions between molecules in a gas can be described by **deterministic** equations for **macroscopic** properties such as temperature, volume and pressure. It is also well known that the **indeterminism** that quantum mechanics postulates for microscopic particles disappears when going to the "classical limit" of **macroscopic objects**" (Ibid).

Thus, there is a **degree of macro-determinism**, framing **micro-indetermination**, and **information** about it can be obtained by using statistical **methods**. (see **data reduction**)

HEYLIGHEN adds: "On the other hand, recent developments in **self-organization models** and **nonlinear thermodynamics** have attracted attention to the opposite **phenomenon**: microscopically **deterministic** systems that behave in a complete unpredictable way when considered from a **macroscopic viewpoint**" (p.378).

As an example, HEYLIGHEN cites: "... certain types of **cellular automata** whose local dynamical **rules** are completely **deterministic** but for which there is no global **algorithm**, allowing to predict their overall **evolution** without computing all the individual, microscopic **transitions** from the given **initial state**" (According to S. WOLFRAM, 1984).

There is thus a relative antinomy – or complementarity, as already noted by POINCARÉ – between **levels** and types of predictability. **Deterministic**, or **algorithmic** predictability would be rigorous, but is practically never possible (even if it may be approached in some cases). Stochastic predictability is frequently possible, but does not allow specific **prediction** for individual **events**. This became clearer with the discovery of **chaotic determinism**.

As expressed by J. CASTI: "Being **deterministic** and being predictable are just not the same thing at all" (1994, p.87).

2610

PREDICTABILITY (Asymptotic)¹⁾

J. BRIGGS and F. D. PEAT characterize a special type of predictability for **quasi-periodic systems**. For such systems it is not possible to make **precise predictions**.

However, the system's **behavior** will always evolve within a specific **toric attractor**, which means that it will not evolve in a totally **random** way in the **phases space** (1991, p.41, French translation).

This is characteristic of numerous physical systems, but is also probably typical of some **sociosystems**, as for example the markets, which offer examples of **quasi-periodic cycles** shrouded in stochastic irregularities.

2611

PREDICTABILITY in chaotic systems (Limits to)^{1) – 2)}

In **strictly deterministic systems**, as stated by P. DAVIES: "...a small **input error** implies a small **output error** in the predictive computation. ...**(While) errors** accumulate with **time**... (they) grow only in proportion to the **time** (or perhaps a small power thereof...)".

However, in a chaotic system "... a small starting difference between two (*nearly*) identical systems will rapidly grow. In fact, the hallmark of **chaos** is that the motions diverge exponentially fast" (1990, p.50).

In the same fashion, in any system with three or more initial independent conditions, **sensitivity** to these **initial conditions** produces the same limits to predictability.

2612

PREDICTION^{1) – 3)}

A statement about some future **state** of a system.

Scientific prediction in the classical sense is limited in practice. It is possible only within the **frame of reference** of precise and limitative conditions.

T. BAUMGARTNER et al. give the following example: "It must be realized that the pinnacle of prediction occurs in physical mechanics and is based upon the concept of the isolated point mass, subject to forces acting at a point. These notions and the basic conservation laws permit derivation of the equations of "point mass dynamics", which can be extended to arbitrary bodies, analyzed as finite collections of point masses, through consideration of the "continuity of **matter**" and calculus. The precision with which astronomical trajectories are determined

and the guidance of spacecraft to within yards of a predetermined landing site provide striking validation of the **models** and the principles upon which they are based" (1976, p.34).

There are however many **situations**, even in physical sciences, where these postulates lead to somewhat, or grossly erroneous predictions (see for example POINCARÉ's **3-bodies problem**) or become downright useless in practice (as in LORENZ **chaotic meteorological dynamics**).

Predictions are thus heavily dependent on the alternative **models** selected to make them. As **data** relative to **processes** can be in many cases accommodated (or fudged!) to different **models** (for ex. **linear**, **logistic**, asymptotic, **exponential growth**), specially when they cover too short a span of **time**, the prediction may very well be implicitly stated within the **model**.

Moreover, biological and **social systems** offer such high degrees of **complexity** that prediction must cover not one, but an **array** of interconnected **processes**. To be *more or less* possible, prediction demand then quite more intricate **methods**.

2613

PREDICTIVE EVENT¹⁾²⁾⁴⁾

An **event** that normally precedes some other event.

The **concept** of predictive event is useful but quite ambiguous. A lightning is most generally succeeded by a thunderclap, because it is its direct **cause** and the **connection** between both is quite evident and immediate.

Some events produce however their consequences in faraway places where they may remain unknown, or after such a long **span of time** that the **perception** of any connection is lost. In some cases distance in **space** and/or time does not suppress the predictive **value** of an **observation**. B.S. ORLOVE et al. have described cases of use of predictive meteorological events made by more or less archaic populations in south America, Asia, Africa and Australia, all of these strictly based on empirical **observations** of clouds or brightness of stars (2002, p. 428-35)

On the other hand, the event becomes predictive for the **observer** who has already witnessed at least one (and better, various) similar sequences of events.

And even this is not enough if the observer has no **model** or **frame of reference** through which the observation makes sense. However, as in the case of so-called ethno-climatology, the frame of reference does not need to be an elaborated scientific **theory**.

→ **Clue; Predictability; Predictor; Prediction; Prospective**

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

2614

PREDICTOR²⁾

A **situation** or setting which implies up to a point some future **states** of a system.

The concept has been used by R. ROSEN, who applies it to initial concentrations of some metabolites in a biosynthetic pathway. ROSEN understands that such a setting amounts to a **preadaptation** (1991a, p.544).

In any system, the present **state**, as well as its functional nature, implies definite **limits** to possible future **transformations**. It may for instance:

- absolutely preclude some
- make some others very improbable
- make others more or less probable.
- render some others unavoidable.

While in some cases the predictor defines quite precisely the future timing (chemical reactions), in others this **prediction** remains elusive (earthquakes, economic recessions).

→ **Percolation, Power laws, System (Composite)**

2615

PREFERENCE¹⁾

The election of an alternative among others, according to some **criterion**.

K. KRIPPENDORFF observes: "Consistent preference orderings are all **transitive** (e.g. if $A > B$ and $B > C$, then $A > C$). Inconsistent preference orderings contain circularities (e.g. $A > B$, $B > C$ and $C > A$)" (1986, p.58).

In complex **situations**, preference orderings can become very tricky, as various **criteria** can be more or less contradictory or incompatible.

2616

PREFERENCES (Collective)²⁾⁴⁾

The problem of harmonization of collective preferences has been considered by K. ARROW (1956, 1963). After his mathematical **modelling** work he came to the conclusion that the only **methods** to clearly define collective preferences from individual ones, if there is a great number of individuals, is to impose them

In MORIN's words (1999b, p. 85) there is no possibility to create a good optimizing **algorithm** in any human collective **behavior**. The definition of the major good or the least evil leads to an **uncertainty** that cannot be eliminated

This reflects or course the multiplicity and **complexity** of the shifting **interactions** which take place in constantly variable ways

It sheds a dispiriting light on the **interrelations** between **cultures**. It could also explain the universal need for **values** and **norms** in defining and strengthening all kinds of social conducts (as expressed by the german term "Gleichschaltung" (= bringing into line), with its unfortunate authoritarian undertones)

But at least some help could conceivably be found in opinion inquiries and polls, even if not conclusive, nor of permanent validity.

→ **Agregation 2**

2617

PREORGANIZATION²⁾

The **set** of **initial conditions** needed in a potentially **self-organizing** system.

M.B. HAWTON (1974, p.87-8) (quoted by D.L. VELKOV – 1989, p.48-50) describes the preorganization **situation** as follows: "In the **self-organizing system** insufficient prior links exist, and the balance of **data** for immediate **control** purposes has to be generated inside the system. This may appear as if by magic, but in practice it has to come from somewhere if the laws of physics are not to be abrogated... no system can be built which is initially **self-organizing**. Initially it must have sufficient preorganization to run the first **cycle(s)**, so as to generate the **information** which will be accumulated to organize future **cycles**. A **machine** can only become **self-organizing** through **operation**".

An example could be the preexistence of the phonation capacity in the newborn, which is the first condition for the future construction of **any spoken language**.

However, preorganization must also have an origin. Thus, the **self-organization** riddle is somehow **recursive** and probably related to a **hierarchy** of **complexity levels**. The existence of **organization** at a lesser level of **complexity**, combined with specific new **environmental** opportunities and/or **constraints** may explain preorganization for a higher **complexity level**.

D.L. VELKOV also quotes H. ATLAN, according to whom "**organization** is meant either as **constraints** between **parts**, i.e. **redundancy** or non-repetitive **order**, i.e. **variety** and inhomogeneity" (Ibid).

A dynamic **mechanism** seems necessary: only **parts entering** in **interaction** generate **new constraints**, in accordance, for instance with H. SABELLI's **process theory**.

HAWTON's views should be compared with V CSANYI's **autogenetic system precursors**, **zero system** and **supercycles** formation. They are also related to the construction of M. EL-GEN's **hypercycles**.

They even may help to understand better the riddle of the relation of **autogenesis** to **auto-poiesis**.

2618

PREPROGRAMMING²⁾

The possibility, latent in systems, to construct behavioral programs.

W. ROSS ASHBY observes that the human **brain** is preprogrammed. Its **organization** is a result of former **evolution** and, at the same time it offers potentialities for more **program-**

ming through training and **learning** (which results quite probably of the progressive ordering – or eventual reordering – of **neural nets**) (1963, p.215)

Thus, the operative capability of the natural intelligent "**machine**" results of progressive **self-programming**, i.e. of the construction of **behavioral algorithms**.

It is likely that efficient high level **artificial intelligence** can be constructed only along similar lines.

2619

PRESENT (The everlasting)¹⁾³⁾

Our historical as well as our prospective **perception** of **time** are mental **constructs** based on an everlasting existential **awareness** (or non-awareness!) of living at the present moment.

What happens (to me) at this present moment is an integrated result of multiple **flows** of **events** converging into my personal perception.

The past is **memory**, i.e. also a reconstructing **phenomenon** at the present moment. So are also our future expectations, which are merely (just now) a speculative mental construct.

P. VENDRYES explained the present moment as the instance of **decision making** by the **selection** of only one **action** possibility among many. That selection precludes the possibility of any other action that we could have selected. This selection **process** is repeated at any future moment.

Another significant aspect is that every individual is enclosed in his/her own present, without any possibility to be influenced at this very moment by events occurring now to others in other places, as there is always a **time lag** in the **propagation** of **effects**.

Moreover psychical **connexions** between individuals requires- also at any present moment- **consensus** on what was and is perceived. Such a consensus is difficult to create and still much more difficult to maintain as "the time flows"

→ **Cycle (Inclusion); Exclusion Principle; Hippocampus; Morphic field; Nervous System; Object-in-time; Perception (Time limits in); Relativity postulate; Simultaneity**

2620

PRIMING¹⁾²⁾⁵⁾

The **process** of triggering an **effect** through an initial **input**.

This quite general **anticipatory process** can be found in physics (priming a pump) as well as in physiology and psychology.

An interesting case is semantic priming, in which a simple glance, or word can lead to the evocation of a much wider significance. An example could be "bomb", which bring **connotations** like "danger", "terrorism", "explosion", etc. (F. & P. LAVIGNE, 2000, p. 3-31)

→ **System (Anticipatory)**

2621

PRINCIPIA CYBERNETICA WEB ¹⁾

Johan BOLLEN (Vrije Universiteit Brussel) describes the Principia Cybernetica Project as a knowledge base for systems research. He writes:

"The Principia Cybernetica Project (PCP, founded in 1989, is devoted to the development of a complete and consistent cybernetic philosophy. The project's name refers to Russell and Whitehead's Principia Mathematica, the work that laid the philosophical foundations for the science of mathematics as we know it.

PCP, however, is not thought of as a closed, rigid set of axioms and definitions. Its basic architecture consists of nodes, representing concepts and their definitions, and links, representing the associations between the concepts. Nodes and links form a dynamic and continuously evolving network, incorporating the knowledge that makes up the Principia Cybernetica.

PCP was not designed as a specialized product of a few scientists, but rather as a collaborative development by many researchers in the field of systems science and cybernetics, each contributing their own viewpoint and expertise. Therefore, advanced collaboration and communication technologies are essential components.

PCP aims to build an adaptive and growing body of philosophical knowledge by applying cybernetic tools and methods to the development of cybernetics itself. PCP encourages multidisciplinary and tries to integrate the different viewpoints that make systems science and cybernetics such a diverse field. PCP investigates the process of collaborative knowledge. The research results will, in the spirit of the project, be fed back into the development of PCP through improvements to software and infrastructure. Our most recent research has focused on dynamically adjusting the structure of a knowledge network so that information will become more easily and efficiently accessible. The idea is to develop learning rules and algorithms that can ensure the network's soundness when the variety of the nodes and links increases. PCP aims to provide an information service to the cybernetics community. Accurate and up-to-date information on the main issues of the cybernetics and systems domain should be readily available to as many people as possible."

(IFSR Bulletin, p. 8-9, Dec. 1994)

PCP can be reached through : <http://pespmc1.vub.ac.be>

2622

PRIORITIES in systemic terms ^{1) - 4)}

In systemic terms, the most important priorities are the global and the **long term** ones. This unfortunately is quite contradictory to the generally **short term** vision and interests of individuals and **communities**, who consciously or not, are frequently disposed to sacrifice median or **long term** futures for quick benefits. G. HARDIN described a typical aspect of violation of global priorities in his "Tragedy of Commons"... without much real echo.

UNEP recommends to give highest priority to "urgent requirements to prevent further irreversible damage to living **resources**, e.g. extinction of species, loss of life support systems, etc..." (UNESCO-UNEP, p.22).

The re-orientation of global priorities is a matter of re-**education**, mainly at deciders **levels**, a very tall order indeed. It is to be feared that priorities will be modified only after the occurrence of considerable disasters, which would be nature's **feedback** to human abuse.

2623

PRIORITY of the SIMPLE ^{1) - 2)}

The necessary pre-existence of simpler **elements** prior to the shaping of more **complex systems**.

This general characteristic of a **hierarchy of complexity** in nature has been emphasized by H. SABELLI, who stated that the existence of simple systems or **organisms** does not depend on the existence of more complex ones, but conversely. Atoms are needed as building blocks for molecules; **cells** could not exist without molecules; nor generally societies without individuals.

However, once simple **components** become embedded in **complex systems**, they depend on the permanence or **survival** of these ones, a situation that SABELLI refers to as **supremacy of the complex**.

2624

PRIORS (Law of Universal) ³⁾

"The human being, **language** and reasoning through **relationships** are universal priors to science" (J. WARFIELD, 1995, p. 137).

WARFIELD contends that "there can be no science without all three of them" (1988, p. 339). The law, of course, unavoidably relativizes human **knowledge** from the **ontological** viewpoint. This is not dramatic, if its *obvious character is understood and taken in account*.

WARFIELD proposes a fourth universal prior relative to the "means to *represent* scientific **knowledge** in a manner that provides Referential Transparency"... as "the **representation** of

scientific **knowledge** forms the **linkage** between the investigator and the scientific **community**, and consequently **representation** is inherent in scientific pursuits".

Referential transparency is generally taken for granted. It implies however the *belief* in "interpretive **symmetry** between originator and receiver of **communications**, summarized in four essentials:

"a) That the linguistic terms needed to represent either exist in the **language** or will be created as required;

"b) that a way to organize the **description** exists or will be created;

"c) that the **design** of the **representation** will employ the foregoing, and

"d) that the **representation** can be assimilated and properly interpreted by both originator and receiver" (p.340).

Doubtlessly, the difficulties for systemists to make themselves understood into their **communities** have much to see with this fourth universal prior: Systemic **language** is still in process of ordering, and the **receivers** do not understand its meaning and possible uses. We should be heedful.

2625

PROACTION ¹⁾²⁾

"An **operation** through which the **output** of the system depends mainly on the capacity to forecast the effects of this **output** upon the **environment** and the system itself" (adapted from J.W. LAPIERRE, 1992, p.221)

This **concept** is very similar to the **feedforward model**.

2626

PROBABILISTIC VIEWPOINT ^{1) - 3)}

Science in general remained mostly **deterministic** till late in the 19th century, a **paradigm** perfectly expressed by the famous **Laplacian deterministic** statement.

The probabilistic view entered, for example through BOLTZMANN statistical **dynamics**, as a more or less opposed complement to **causal determinism**. It appeared as a kind of stochastic legality, merely juxtaposed to rigorous **determinism**, in the worst case.

The first inklings that these **dichotomic** views were too simplistic came through POINCARÉ'S **n-bodies problem**, which showed that even celestial mechanics could not be absolutely **deterministic**. The **trajectories** vagaries in POINCARÉ **phases space** were the first indications that **determinism** and **randomness** were more closely connected than hitherto believed.

The **chaotic behavior** recently discovered in many **phenomena** has emphasized the existence of movements which are globally **deterministic**, but anyhow unpredictable, or nearly so. This is also the case with **emergent dissi-**

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

pative structures, that depend on **random nucleation** at **bifurcation** points. As a result, it is now becoming widely admitted that **determinism** and **randomness** are inseparable aspects of **processes** and **systems** behavior.

2627

PROBABILITIES (STATISTIC) and STATISTICAL FREQUENCIES^{2) - 3)}

Statistics on probabilities are *relative to the past*: They reflect the numerous and varied results of a **random process** that already has taken place, and thus they are not any more probabilities. They are a rationalization of historical, unchangeable evidence, even if they provide us with at least a measure of **information** about the *nature* of the **process**.

P. VENDRYES clarify this point as follows: "When the same **random process** is repeated a great number of times, each time requires independence of the repetitions. The relative **frequencies** of the various possible outcomes tend towards the respective probabilities of each outcome. This tendency increases with the number of repetitions. These **frequencies** endow the probabilities with realistic values. They have been referred to as statistical probabilities. But these **frequencies** were actually manifest in the past, and *belong* to this past, whereas the probabilities are *virtual* and are turned toward the future" (1989, p.148).

Synthetically, **frequencies** are historical while probabilities are conjectural, i.e. based on some hidden postulates. The result, as stated by E. JANTSCH is that: "Most of the **models** applied so far assume **equilibrium** conditions and define probability accordingly", while "The recognition of **nonequilibrium** conditions ... leads to vastly different concepts" (1975, p.198).

2628

PROBABILITY¹⁾²⁾

The quality or condition of an **event** more or less likely to happen

This definition shows that probability implies necessarily a **criterion of evaluation**, i.e. depends on the **observer** in his/her specific mental, intellectual and even possibly affective or emotional state

However, once the conditions of **observation** have been clearly defined it becomes possible to introduce a more precise definition of what we mean by probability. As an example, the American Heritage Dictionary, under the sub-heading "Mathematics" defines probability as "a number expressing the likelihood of occurrence of a specific **event**, such as the ratio of the number of experimental results that would produce the event, to the total number of re-

sults considered possible" (p. 1043). Still, the use of the word "considered" shows the need for a criterion, normally obtained from a theory or some other **frame of reference**

2629

PROBABILITY (BAYESIAN)^{2) - 3)}

"The measure of the **plausibility** of an hypothesis or proposition".

Bayesian probabilities offer a measure of subjective **evaluations**.

Such probabilities "cannot readily be understood as **frequencies**, but they have a natural interpretation as indicating the speaker's degree of belief or confidence in the statement, given the available evidence" (W.H. JEFFERYS & J.O. BERGER, 1992, p.66).

Bayesian probabilities are used to quantify a belief or hypothesis related to some **situation** that cannot be experimentally repeated or produced, in which case no **frequencies** can be measured.

Of course "... subjective estimates (can) be modified as new **information** becomes available, leading to the revisions of a priori probabilities" (J.van GIGCH, 1978, p.202).

Generally, new information "more or less"-settles within the brackets of the former probabilities evaluation. "More or less" means that the effect of the new information will in most cases lead to narrower brackets of evaluation, i.e. diminishing the spread between upper and lesser values. An interesting practical example has been given by some marine biologists who re-evaluated the rockfish stocks in California (K. SHMIDT, 2003, p. 44-47)

→ **Fluctuation; Predictability; Randomness (Constrained); Randomness reduction**

2630

PROBLEM¹⁾

A ill-defined or **messy situation** or **issue**, which must be understood, decided-on and managed.

This is one of the most over-used word in our time.

But, to begin with, what does it mean? And, more specifically, what does it mean for systemists?

It seems to be generally accepted that a problem is a conflictive **situation** that should be somehow changed and "solved". We thus have "**problem solving**" and problem solvers. A leaky faucet can be a problem, but is obviously not in the same class as the world stock and distribution of nuclear bombs or the drying up of the Aral Sea.

For cyberneticians "a la WIENER" a faulty or inefficient **control** is a problem, while for a cybernetician "a la von FOERSTER" misunderstanding of so-called **facts by observers** is one, or for G. PASK it could be a confusing **conversation**.

For systemists "a la FORRESTER" it could be an incorrect **model** for **systems dynamics**, or for van GIGCH, a result of the neglect of the **metasystem** conditions, or for **networking** fans, an insufficient **understanding** of the **network** and of its possibly **chaotic behavior**.

We need not select our pet type of problem. We should understand that all the signaled types of problems – and many others – are frequently intertwined.

The very important general result of this situation is that we are always facing the following dangers:

- Forget that a problem has generally many facets. In the somewhat overdone definition by C.W. CHURCHMAN: "Something is a problem if and only if it is a member of the **set** of all other problems" (As quoted by I.I. MITROFF and H.A. LINSTONE, 1993, p.109).
- Try to apply partialized solutions to complex problems
- Remain inoperant because we cannot make up our mind in order to seek at least some solution, even if not **optimal**.

Solving a problem must not be restricted to purely **linear deterministic methods**. There may be good reasons to try to solve the problem in various ways. In many cases, **creative** insights may well deeply modify the terms of the problem and offer help to manage it.

Various recent systemic **methodologies** are tackling the "problem of understanding, managing or solving problems" as for example **Unbounded System Thinking** (I.I. MITROFF and H.A. LINSTONE), **Generic Design** (J. WARFIELD), **Design Conversation** (B. BANATHY and FUSCHL Group), **Total Systems Intervention** (M.C. JACKSON and R.L. FLOOD).

A curious aspect about problems is that, when they emerge to **consciousness**, they imply a newly structured vision... and in some individuals, the first insights about new **methods** for their solution. **Emergence** of systemics at the precise time of the appearance of numerous **situations** of high **complexity**, in which humanity has enmeshed itself, is surely not casual: it is a kind of individual and collective reaction, that may lead to "**distributed problem solving**".

2631

PROBLEM CONTEXT¹⁾

The **set** of conditions that produced the problem and may influence its present and future character.

M.C. JACKSON writes: "A problem can be defined to include the individual or **group** of individuals who are the would-be **problem solvers**, the system(s) within which the problem lie, and the **set** of relevant participants. This **set** contains all those who can make **decisions** that affect the **behavior** of the system(s)" (1992, p.27).

2632

PROBLEM DIAGNOSIS¹⁾

Any diagnosis reflects necessarily the specific viewpoint and aims of the **observer**. However some general guidelines are useful in all cases.

The most difficult stage is probably the first one, i.e. symptoms detection, for the following reasons:

- We see that what we are looking for, what we are prepared to perceive in accordance with our past experience, while we tend to remain blind and deaf to anything else;
- We have a very imperfect **perception of time scales**, i.e. of the **differences between short, medium and long term processes**;
- We mostly lack the capacity to perceive complex **interrelations** and frequently miss to perceive even the most obvious and critical ones (see FRANÇOIS's study of Man-made disasters – 1989b).

All this adds up to De ZEEUW's **invisibility** and FOURASTIÉ's ignorance of ignorance.

Once the symptoms partly or totally observed, we must understand their **meaning**, trying to sort out the subjective part of our interpretations. This search for **meaning** should also be creative by forming hypotheses about the possible **interrelations** between symptoms and by searching for other clues in apparently unrelated areas, without of course overextension (in itself a subjective **criterion**) of this **inquiry**.

Finally, it may be useful to construct a formal **model** of our **diagnosis**. This is however also a risky endeavor, since formal **modelization** is subject to **rules** whose use may or may not distort the observed **situation**.

2633

PROBLEM FORMULATION²⁾

The statement as precise as possible of the unsatisfactory **situation** or **issue**, in relation to the possibilities to correct it.

Apart from the difficulties of the **diagnosis**, problem formulation depends on the viewpoint of different **stakeholders**. The unilateral view of only one or some of them, when imposed through the use of authority, frequently leads to new problems.

Given these caveats, we can follow K. KRIPPENDORFF's description: The problem can be identified by specifying:

- "a) the undesirable and problematic **state** currently occupied,
- "b) the **resources** currently available to move away from that problematic **state**, particularly the available courses of **actions**, the combinatorial **constraints** on using them, etc, and
- "c) the **criteria** that need to be satisfied to say that a problem no longer exists or is solved" (1986, p.61).

J. WARFIELD's **Interpretive Structural Modeling** seems to be the most efficient **methodology** for problem formulation.

2634

PROBLEM (How do we define a)²⁾

In his paper "**Perception** of the future and the future of **perception**", H.von FOERSTER thus quotes H. BRUN: "The definition of a problem and the **action** taken to solve it depend on the view which the individuals or **groups** that discovered the problem have of the system to which it refers. A problem may thus find itself defined as a badly interpreted **output**, or as a faulty **output** of a faulty **output** device, or as a faulty **output** due to a malfunction in an otherwise faultless system, or as a correct but undesired **output** from a faultless and thus undesirable system. All definitions but the last suggest corrective **action**, only the last definition suggest **change**, and so presents an unsolvable problem to anyone opposed to **change**" (1971, p 1-10).

The basic point is that "correction" does not imply "**change**", while "**change**" is sometimes absolutely necessary to insure that "corrections" should not merely be superficial, deceptive and, in last resort, useless patching.

Even so, a good **knowledge** of the system is needed if the thus considered "**change**" is not to play havoc with the whole system. Many **changes** are always possible, but each proposed one should be in accordance with the global **organization** of the system.

And finally, one should never forget that any **change** may merely *displace* the problem. As observed once by B. BANATHY: "You cannot solve a problem, you only can manage it".

J. WARFIELD proposes to clarify the definition of any problem by covering the following points:

- "1. A well-conceived title for the problem or **issue**.
- "2. A descriptive **scenario**, explaining the nature of the problem, and how it came to be a problem, presenting as much history and **data** as can be prepared with available **resources**.
- "3. An **understanding** of what disciplines or professions are relevant to an attack on the problem.
- "4. An **assessment** of scope.
- "5. A determination of the societal sectors involved.
- "6. An identification of the actors to be involved in the problem-solving **situation**.
- "7. An identification of need.
- "8. An identification of alterables (those **elements** of the system that are subject to **change**)
- "9. An identification of major **constraints**.
- "10. Some partitioning of the problem into relevant **elements**.
- "11. Some isolation of the subjective **elements** of the problem

"12. Description of **interactions** among relevant **elements** of the problem" (1989, p.150).

2635

PROBLEM (Ill-structured)^{2) - 4)}

A problem "which cannot be expressed in precise terms" (P. CHECKLAND, 1976, p.131).

Problems implying ecological and/or human factors are by necessity ill-structured because they can normally not be reduced to precise quantification. Or quantification would be simply an artificial way to eliminate psychological or sociological non quantifiable **values**.

CHECKLAND, who established the concept, states: "Their crucial characteristic is taken to be that they are *unstructured*, and the aim has been to find a way of using systems ideas to tackle them without having first to define them sharply, without forcing them into a structured form. This is deemed necessary because if a problem is stated in a well-defined form its solution is usually implicit in the definition, and such "solutions", in real-world problems, tend to pass the problem by. In the **management** science area, for example, we all learn to recognize the **queuing theory** enthusiast who readily sees problems as queueing problems, thus enabling him comfortably to use his favorite technique" (p.132).

CHECKLAND proposes "... a more open analysis of *the situation within which a problem is perceived*" and, of course who perceives it".

When the **situation** is clearly perceived by the various actors "... debate ensues which aims to define **changes** which meet two **criteria**: are they arguably *desirable*?; are they, in the **situation** we have, *feasible*? If *desirable* and *feasible* **changes** emerge then **action** in the original problem **situation** is possible. If **changes** meeting those two **criteria** do not emerge, then we may explore more radical or more conservative viewpoints via further conceptual **models** – and in so doing *learn*. The **methodology** is in fact a **learning** system (in contrast to those **methodologies** for "hard" **systems engineering** which deal in terms of "**design**" and "**optimization**" and "implementation") (Ibid).

In this way, CHECKLAND's **methodology** deals with the relative **invisibility** of the environmental **situation** of the problem, a very dangerous feature when **decision-making** is needed about supposed "*desirable*" and/or "*feasible*" **change**.

Let us note however that the **concept** of **design** has evolved notably since CHECKLAND wrote these lines.(1976)

→ **Problem (Well structured)**

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

2636

PROBLEM SET²⁾³⁾⁴⁾

The word "problem", after being used and abused widely all along time, has finally lost any clear meaning for most people. J. WARFIELD writes: "Extensive empirical evidence in working with **complexity** has made clear that the statement "let's begin by defining the problem" is the opening scene of an evolving linguistic nightmare". Whenever complexity is involved nearly all **stakeholders** in some **situation of issue** have different views about what the "problem" is. This is the recipe for confuse, or even incoherent debate, for muddled thinking and inefficient meandering **management** through "**underconceptualization**" as defined by J. WARFIELD.

In effect, the apparently clear **concept** of "the problem" totally obscures the fact that most problematic **situations** have multiple concurrent (and even **synergetic**) **causes**.

It tends to lead astray the would be "problem solvers" making them believe that, "finding "the" cause of the problem", it will be easy to "solve".

Warfield proposes to consider what he calls a "problem set", which would include as many as possible of the converging causes of different kinds, at different **levels**.

He also observes that any problem definition is a human construct, and as such, of course, depending on probably different and even divergent views of the **stakeholders**.

Unless a wide-open **conversation** is instigated with an appropriate technique, the so-called "problem" would probably be misunderstood and conflicting unresolved views would lead to **underconceptualization**, leading in turn to costly mistaken **decisions**.

→ **Clanthink; Design (Generic); Group technique (Nominal); Groupthink; Solution**

2637

PROBLEM (Soft)¹⁾⁴⁾

Generally a real world problem that cannot merely be tackled in terms of seeking convenient means to reach a simple determined **goal**.

In soft problems - characteristic of the real world **issues** - the **stakeholders** are in most cases numerous and of different classes. As such they frequently have different outlooks and **goals**, rooted in different worldviews and intentions. This makes the problem very difficult to understand for anyone (J. WARFIELD's "**Underconceptualization**"), to modelize and to manage. This led P. CHECKLAND (1981) to his Soft System **Methodology** and, more recently R. RODRIGUEZ ULLOA (1994) to his **Soft Systems Dynamics Methodology**, which combines FORRESTER's **Systems Dynamics**

(1961, 1969, 1971) with CHECKLAND's approach, adding moreover a cultural angle, very significant in intercultural interventions and in culturally **heterogeneous human groups**.

2638

PROBLEM SOLVER¹⁾

Someone who is supposedly able to offer a solution to a problem.

von FOERSTER writes: "... there are no problem solvers, because they do not have any problem in the first place. It is *our* problem they help us to solve, like any other useful tool, say, a hammer which may be dubbed a problem solver for driving nails into a board. The danger in this subtle **semantic** twist by which the responsibility for **action** is shifted from man to a **machine** lies in making us lose sight of the problem of **cognition**" (1981, p.237).

Such a caveat is surely justified: as we all know, when some mistake had taken place, the (ir)responsible factotum was always inclined to tell us: "The computer made a mistake". Of course, nobody believes that anymore nowadays.

Farther afield, no **machine** can give a correct answer if fed with an incorrect **model** of the question or **situation**. ("Garbage in, garbage out").

As to her/his practical **efficiency**, the problem solver depends on the tools mastered: "... the challenge is to find **algorithms** that give reasonably good solutions reasonably quickly" (R. MATTHEWS, 1995, p.42). Recently, the arsenal of the problem solver has become enriched with new tools, as for example **genetic algorithms** and **connectionist models**.

2639

PROBLEM SOLVING^{1) - 2) - 4)}

"An **activity** aimed at closing the cognitive gap en route to a **goal** by employing acts of **processes** neither immediately nor obviously suitable towards this end" (K. KRIPPENDORFF, 1986, p.61).

Problem solving has been discussed by H. SIMON, in relation to specific tasks as for example "discovering the proof of a difficult theorem". He states: "The process can be - and often has been - described as a search through a maze. Starting with the axioms and previously proved theorems, various **transformations** allowed by the **rules** of the mathematical systems are attempted, to obtain new expressions. These are modified in turn until, with persistence and good fortune, a sequence or **path of transformations** is discovered that leads to the **goal**" (1965, p.67). He adds: "The **process** usually involves a great deal of **trial and error**... which is not completely **random** and blind". (We are up to a point, guided by the **rules**). As a result, **trial and error** search is "selective" (Ibid).

Problem solving is however generally referring to very much more difficult issues.

This seductive - but sometimes deceptive - concept effectively conceals quite different **situations**. The resolution by computer of a mathematical problem or geometric theorem; the inquiry about some specialized problem by an **expert system**; or the difficult **process of decision-making** by a businessman or a statesman are widely different matters.

The first type corresponds to a very simple sequence from the abstract **model** to the solution, still in the abstract world of the **model**.

Once we deal with a **concrete system**, three other - and quite critical - steps must be taken. The first is the construction of the **model**, in which the **percepts**, concepts and intentions of the **model builder(s)** are heavily conditioning factors. The second one is the interpretation of the abstract solution obtained from the **model** (through some supposedly correct **methodology**) in relation to the **concrete system's** nature and conditions (which supposedly kindly remained **invariant** in the mean time), and the third one is the implementation of the solution in the **concrete system** (which implies many human and practical **resources** and **means**, hopefully at disposal).

It is thus not surprising that about real world **situations** B. BANATHY says: "You cannot really solve a problem, you can only manage it". In the same vein, as stated by P.M. ALLEN: "Clearly, what constitutes a "problem" and what is considered a "solution" depend on the particular views of the moment, and any **action** taken with the intention of providing a solution to a problem will in fact push the system along one evolutionary **path** rather than another. Since such **decisions** are usually taken without any real **knowledge** of what the system would have done anyway, and what new problems lie along its changed **path**, then it is not surprising that the general feeling as to the overall effect of such interventions is somewhat less than euphoric" (1982, p.60). No wonder G. VICKERS spoke of "the poverty of problem solving"

→ **(Planning (Anticipatory) and Planning (Interactive))**

To these reflexions, D. Mc NEIL adds the following: The "Problem-solving **paradigm**" "pretends to **objectivity** and the particular rationality of a **linear** world which is reducible to "things out there". It presumes that a technological arsenal of "problem-solving tools" could mechanize and eventually offer mastery of **prediction** and **control**. Ultimately, the "problem-solving" **paradigm** provides at best only a patchwork of partial, local and temporary "solutions" to "problems" which are themselves the results of "solutions to problems" ad infinitum" (1993a, p.3).

Problem-solving also presents a significant cybernetic angle, as stated by P.S. HENSHAW: "Knowledge of the outcome of the last previous act is a key to problem-solving, **decision-making and behavior**" (1975, p.23).

It is even more complex than this, because the **situation** may very well have changed due to new and yet unregistered **environmental** factors which may render our **solution** – now out of step – inoperant or even downright harmful.

G.S. SAMARAS indicted (in 1974, but it is still true nowadays): "... the prevalence of erroneous problem-solving – the 'cybernetic sacrilege' of viewing **complex systems** with superficial oversimplification. A fundamental element of any problem-solving, **decision-making process** is determining whether the observed **phenomenon** is an "isolated" **state** of superficial cause or a manifestation of some subtle, underlying source. Many current **decisions** treat our complex problems as **states** instead of symptoms. The implementation of these ineffective solutions is abetted by the lack of involvement of the scientific **community** and the ignorance of the general public" (1974, p.1).

KRIPPENDORFF emits a more or less similar caveat: "The contemporary emphasis on finding technological solutions to human problems is the principal motor for the **growth** of technology, but also the principal source of ecological **disequilibria** and of many human problems and social **instabilities**" (p.86).

This "problem with problem solving", particularly in **human systems**, is now more clearly perceived and various new systemic **concepts** and **methodologies** have emerged during the last twenty years:

- St. BEER **Viable System Model**
- R.L. FLOOD and M.C. JACKSON's **Total Systems Intervention**
- The FUSCHL Group's **Design Conversations**.
- J.A. JOHANNESSEN and A. HAUAN's **holographic and heterarchical model of the organization**
- I.I. MITROFF and H.A. LINSTONE's **Unbounded Systems Thinking**
- J. WARFIELD's **Generic Design** and associated **methodologies**

P. CHECKLAND's "**Soft Systems methodology**" and C.W. CHURCHMAN's views about the "**Design of Inquiring Systems**" have inspired most of these developments.

2640

PROBLEM (Well structured)²⁾

According to A. NEWELL: "A problem is well structured to the extent that it satisfies the following **criteria**:

- "1. It can be described in terms of numerical **variables**, scalar and vector quantities.

"2. The **goals** attained can be specified in terms of a well defined **objective function** – for example, the **maximization** of profit or the **minimization** of **cost**.

"3. There exist computational **routines (algorithms)** that permit the solution to be found and stated in actual numerical terms" (as quoted by J.van GIGCH, 1978, p.379).

This stand is obviously referring to quite simple business, or economic, or technical problems where abstraction can be made of human (and possibly qualitative ecological) factors.

van GIGCH observes "... ill-structured problems are amenable only to solutions by **heuristics**".

→ Problem (ill structured)

2641

PROBLEMATIQUE¹⁾

"A **graphical pattern** showing how members of a set of **problems** identified in a given **situation** aggravate or do not aggravate one another" (J. WARFIELD, 1995a, p.160).

The **pattern** represents the interconnected **set** of all **interactions** between the **elements** of a complex **problem**, as discovered through **Interpretive Structural Modeling** used by a **group** as representative as possible of all **stakeholders**.

As stated by J. WARFIELD and R. CARDENAS: "... it is the primary basis for **understanding** how the **effects** of work done to diminish **problems** propagate into the total **program**. If, for example, someone diminishes a certain **problem**, but does nothing to diminish those other **problems** that have been aggravating it, it is very likely that the **problem** that was diminished will make a strong comeback, and nothing useful will have been accomplished; while time will have been lost" (1994, p.307).

The **problematique** is thus useful in order to discover and if needed, eliminate undesirable **side effects**.

J. WARFIELD comments: "One of the significant values in such a **pattern** is that it reveals, to those who have produced it, the small **sub-set** of **problems** that are highly influential in preserving the problematic nature of the **situation**; while also revealing which **problems** tend to be created by other **problems**. In addition, it often reveals the presence of "problem cycles"; i.e. **subsets** of **problems** that are mutually aggravating, tending to form a small **problem** world unto themselves, and giving a clue to the actors that such **cycles** may have to be dealt collectively with a **strategy** that recognizes the reinforcing **feedback** at work".

WARFIELD gives a graphical example, from which "it is very apparent that the **problematique** is not **linear**" (p.161).

A different, but more limited and less significant meaning is given to **problematique** in France, as "A world **representation** which questions the observed results" (M. LIU, 1989, p.41).

Here, the **problematique** affects "the **observer**", i.e. not a **group**, but merely an individual.

According to M. LIU: "A **problematique** is, for the **observer**, linked to some **situation** from which it arises...

"The **problematique**, as defined by a researcher, is linked to his own **situation**...

"A **problematique** is deduced from a **situation** by way of a **diagnosis**." (Ibid.)

Obviously, a **diagnosis** will be more valuable if resulting from the **consensus** in a **group** of **stakeholders**.

Warfield advocates the replacement of the expression "complex problem" by "problematique" in order "to show how the different **component** problems of what might be otherwise called a "complex problem" are interrelated, leaving aside the human tendency to want to think in terms of a one-**element set** (e.g. "the problem", free of interacting members)"

In his view this would eliminate simplistic and illusory **solutions** which generally lead to the re-emergence of the "problem".

J.N. WARFIELD and C.H. PERINO Jr. in a more recent paper explain that **problematique** as a concept and methodology "benefited from the writings of ARISTOTLE, ABELARD, LEIBNIZ, DE MORGAN, C.S. PEIRCE and HARARY". They add that the idea "has been extended to represent a structural portrayal applicable to specific problematic **situations**" and "Having been tested in many such situations, it can now be viewed as a standard format of wide utility in many applications"(1999, p. 221)

→ **Interpretive structural modeling; Interactive management; Problem solving; Soft system methodology; Total system intervention**

2642

PROBLEMATIQUE OF TECNOCENTRIC SOCIETIES⁴⁾

"The contemporary **problematique** is the result of a still prevailing **value** system based on expansion, **competition**, domination and exploitation"(unstated source)

It would seem that every historical expansive **socio-cultural system** rested on this typical **behavior**.

Moreover, the success of most former empires seem to have been due to adequate **sub-systems** of **communications**, **exchange**, and administrative **organization** in coincidence with a certain superior state of technical development or in accordance with some specific characteristics of the **environment** (Island, plains, deserts, etc.)

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Older examples have been the military use of horses, the invention of gunpowder, the introduction of good instruments for oceanic navigation, of the steam engine and the internal combustion engine.

In a sense all of the successful human **groups**, states or empires have been made possible by some technical superiority.

However, in our contemporaries societies, technical **progress**- especially thought the use of highly concentrated energy led to the absolute **dominance** of technical **subsystems** within the general **organization**. In the older societies, even the quite limited power of techniques always ended in some crisis, be it for their insufficiencies, be it for more or less widespread abuse against the human or natural environment.

Technique tends to act as a magnifying lens and empowering device on anything it is applied to.

As our modern societies are hypertechnified, a better **evaluation** of the impact of technique on all human systems and subsystems seems to be in urgent need to enter our **systems research** agenda.

PROBLEMS (TYPOLOGY of)¹⁾

Typification of problems is a thorny issue.

However, at least one basic **criterion** should be applied: Problems are **linear** or **nonlinear**.

Linear problems respond to simple **models**, but must be of the ... *et ceteris paribus* type, i.e. they must be immune to any **changes** of their nature, or environment, a quite improbable **situation**.

Complex systems present mostly **nonlinear** problems, resulting of a **variety** of **behavior modes** as, for instance: be submitted to **regulations**; respond **simultaneously** to different **cyclical activities**; obey to **chaotic determinism**; be close to an **instability limit** due to **dissipative structuration**; be **organizationally closed**, etc...

Using **linear models** to solve **nonlinear** problems leads normally to pseudo-solutions. It is possibly still more dangerous to be unaware of **linear** assumptions that one may bring unwittingly along when searching for solutions.

The most insidious of all is the belief that **nonlinear** problems can have perfect and complete solutions.

2644

PROCEDURE¹⁾²⁾

A set of established **methods** or sequence of **actions** prescribed to manage specific kinds of systems or **issues**.

Procedures generally include some more or less automatic **behaviors** or **routines**.

2645

PROCESS^{1) - 2)}

1) "Any **change** over **time** of **matter**, **energy** or **information**" (J.G. MILLER, 1978, p.23).

2) "A sequence of **behavior** corresponding to a **goal-producing function** in a system" (Adapted from R.L. ACKOFF, 1972).

M. CERÉJIDO writes: "Systems do not undergo processes; they are the **forms** that manifest the processes" (1978, p.32). Obviously, as observed by E. JANTSCH (1976), suppression of processes with the illusory **goal** to stabilize **structures**, would lead to the total (and impossible) blocking and invariability of the system, while fugacity of **structures** would produce a total lack of **coherence** in processes. In none of these cases could a system survive.

A process presents three basic aspects:

- A **function** of transference in **time**, through **storage** or **memory**;
- **Functions** of **transfer** in **space**, i. e. displacements or **transmission**;
- **Functions** corresponding to morphologic changes: variations in **form**, or of **information** content. (After J.C. LUGAN, 1993, p.95).

Of course, any process is **energy** driven and any transference is in **space and time**.

MILLER writes: "If the equation describing a process is the same, no matter the temporal **variable**, it is a **reversible** process; otherwise it is **irreversible**, or better less readily reversible" (Ibid).

He adds: "Process includes the ongoing **function** of a system, reversible **actions** succeeding each other from moment to moment... Process also includes **history**, less readily reversed **changes** like mutations, birth, **growth**, **development**, **aging** and death; **changes** which commonly follow trauma or disease; and **changes** resulting from **learning** which are not later forgotten" (Ibid).

All these "less **reversible**" **changes** are practically totally **irreversible**. Further comments of MILLER show that the word "reversible" must be understood as "which can be replaced or reconstructed" and not in its abstract mathematical **meaning** "**time invariant**" (see the critique of the concept of **reversibility**).

As to ACKOFF, he comments: "The sequence of **behavior** that is performed by the electronic rat constitutes a maze-solving process... The **metabolic** process in living things is a similar type of sequence the **goal** of which is acquisition of **energy** or, more generally, **survival**... Process **behavior** displayed by the system may be either reactive, responsive, or active" (Ibid).

2646

PROCESS (Anticipatory)²⁾

A process proper to a system able to construct a working **model** of its **environment** and use it for **decision making** and **forecasting purposes**.

Because of the **survival value** of such abilities, it is probable that they impelled the differentiation and complexification of the **nervous system** all along the **evolutive process**.

Anticipatory processes are now widely recognized in biology and in **cognitive sciences**.

The subject is also closely related to **computation** and to **neural networks**.

It has become the focal point of the **CHAOS Society** (Centre for Hyperincursion and Anticipation in Ordered System) based at the Institute of Mathematics, University of Liège, Belgium.

2647

PROCESS (Dissipative)^{1) - 5)}

The process of dissipation of **energy** in a system.

I. PRIGOGINE emphasizes that: "Dissipative processes that destroy **structure** at and **near equilibrium**, may **create** these **structures** when sufficiently **far- from- equilibrium**" (1984, p.47).

In such cases, the system is trying to cope with an **overload** of **energy** through the search for a new **dynamic equilibrium** at a higher **level of complexity**.

2648

PROCESS (Generative)

→ **Process Theory**

2649

PROCESS CONTROL²⁾

The permanent **adjustment** of the **process** in order to maintain it in correct working order.

In cybernetic terms, this is obtained through **feedbacks**.

In **learning** in a **neural network**, **control** is implicit in the **parallel distributed processing software**.

2650

PROCESS INTERACTIONS during autogenesis²⁾

According to BERTALANFFY "... the **primary regulations** in organic systems (i.e. the most important **regulations** in embryonic **development** and in **evolution**) were rooted precisely in **dynamic interaction**" (1940, p.57).

This implies that complex and, to begin with, non-hierarchical interactions precede **regulations**. This seems possible during the **auto-genesis** phase of any class of systems, when the **whole** can still be reestablished from a **part**, as for example in the famous experience by DRIESCH with divided embryos of urchins.

→ **Autogenetic systems precursor (CSANYI, 1993, p.263).**

2651

PROCESS METHOD ^{1) - 2)}

H. SABELLI derives a "process method" from his **process theory**: "Postulating that everything is a process, **process theory** leads one to study **time series** as **models** for nature. **Process theory** postulates that all processes include simple **components** the form of which can be described as numerical orders: (0) the **disorder** of **randomness**; (1) oneness of temporal **asymmetry**; (2) twoness of opposition or **symmetry**; (3) tridimensionality of **space**. These simpler forms combine to generate spiral **components (FIBONACCI series 0,1,2,3,5,8...)** and to create complex multidimensional **components**... We apply this idea to the study of mathematical **time series**, and **time series of data** obtained from complex biological processes, using the **time delay** method to construct dimensional frameworks..." (1994, p.1488).

2652

PROCESS MODEL ¹⁾²⁾³⁾⁴⁾

"An organized arrangement of systems **concepts** and principles that portray the **behavior** of a system through **time**" (K. BAUSCH, Glossary, pers. comm., 2002)

BAUSCH adds: "Its **metaphor** is the "motion - picture" or "movie" of the system" (Ibid)

In fact, the choice of the "concepts" and "principles" is of enormous importance.

There are many kinds of processes, as for example different types of **growth** processes; **continous discontinous** processes (cyclical processes of various types, **self - organized criticality**, **equilibria** of different types, **synergetic** processes)

The **modelling** of any process implies either an **interpretation** of experimental results, or the selection of a specific model, in an hypothetical way to begin with. Generally both **modes** of reworking of the **data** must be simultaneously used.

The difficulties are still more severe when modelling human economic, or social processes, due to the psychological and cultural aspects of model selection.

→ **Model accuracy; Model building; Modeling (Systemic); Models (Functions and uses of); Modelization; Modelization Methodology; Process theory**

2653

PROCESS (Self Amplifying) ^{1) - 2)}

A process submitted to a positive feedback.

Such processes are driven away from equilibrium and can lead:

- either to explosive destruction
- or to **emergence** toward a higher organizational level.

However, in **autocatalytic** processes, there is no more than a self-amplification limited in time.

2654

PROCESS (Self-destructive) ^{1) - 2)}

A process affected by a repetitive **feedback** which tends to finally annulate it.

The **feedback** may be **positive** or **negative**. A **positive feedback** leads to the exhaustion of some **input** or **environmental** condition basic for the **maintenance** of the process or the **survival** of the system in which it is functional. Examples are the exhaustion of oxygen for a fire in a closed **environment**; the growing **costs** of scientific research, the progressive clogging of traffic by a growing number of vehicles and the acceleration of technological obsolescence.

The **negative feedback** reduces either the **inputs** or the width of the **fluctuation** band of the process, and progressively stifles it. Examples are starvation or reduced **resilience** in **ageing living systems**, or declining **adaptability** in an **organization**.

The only way to avoid self-destructiveness in processes is a convenient blend of **negative** and **positive** feedbacks.

2655

PROCESS (Social Distributing) ⁴⁾

The way a wide **variety** of tasks are allocated or re-allocated in a **social system**.

Distributing processes have been researched experimentally in ants nests by D.M. GORDON through a **variety** of perturbing experiments affecting the **environment**, or the **population structure** of the ants. (1995, p.50-57)

The general conclusion is that the distributing process is the global result of **networking** through multiple **communication** among the ants.

GORDON also observed that global **order** is more stable in mature colonies than in new ones. Her conclusions are quite probably also valid in **human systems**, where more or less spontaneous **reorganization** can frequently be observed when they are violently and suddenly disturbed, as for example in war or massive terrorist attacks, or great natural disasters.

2656

PROCESS THEORY ^{1) - 2) - 3) - 4) - 5)}

A **General System theory** organized around the **dynamics of processes**.

Process theory (P.T.) has been introduced by H. SABELLI (1989). He states: "P.T. adopts as its basic postulate PASTEUR's **concept** of cosmic **asymmetry**, i.e. the existence of **asymmetry** in all and each entity, in all and each of its qualities, an **asymmetry** that provides processes with **energy** and **order**... Systems are asymmetric **organizations** of **energy**, **information** and **matter** created by the **interaction** of opposite forces... Every system has an inside-outside **asymmetry**, a past-future **asymmetry**, and an **energetic asymmetry**" (L. CARLSON-SABELLI & H. SABELLI, 1992, p.681).

Moreover, "P.T. postulates the **bifurcation** of opposites, not their synthesis, or their annihilation" and "P.T. proposes that **chance** and **cause** have **priority**, while **choice** and **creativity** have **supremacy**" (H. SABELLI & L. CARLSON-SABELLI, 1994).

And: "According to P.T., **levels of organization** are **topologically embedded forms**, ordered **hierarchically** from simple to complex" (Ibid) In **human systems** "P.T. offers a framework within which to study social processes: the law of biological **priority** and psychological **supremacy**" (Ibid).

On the other hand, "According to P.T., the co-existence of three or more oppositions creates partial **equilibria**, i.e. **structures**" Moreover: "Processes create **structures** and **structures** create processes" (Ibid).

SABELLI proposes three basic laws of P.T.:

"1. Energetic asymmetry: All is **action** (where **action** = **energy** x **time**) Thus everything spontaneously changes and exchanges. Everything is a process, i.e. a composite of **actions**, and hence have two **asymmetries**, the potential of **energy** and the unidirectionality of **time**. Because all processes are forms of the same **energy**, they change in the same direction, **time**. **Action** is universal **asymmetry** of nature.

"2. Entropy as symmetry: universality of opposition: Every process and every **structure** includes two opposite **components** (**enantiodromia**): attraction and repulsion, union and separation, **asymmetry** and **symmetry**, left and right, positive and negative. For instance, every physical force of attraction has a **range** at which it repels. Gravity itself is counterbalanced by the spontaneous expansion of the universe. Every **change** generates its opposite, so processes increase their internal **symmetry**, tending toward **attractors** and forming **structures**. **Symmetric equilibrium** is always partial and local. Isolated from **interactions**, processes flow toward stable **attractors** - a fundamental **asymmetry** of nature - but an **attractor** is a balance of **symmetry** between opposites.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

"3. Co-creative **organization**: the generation of **complexity**: Natural processes spontaneously create material **structures**, i.e. **asymmetric patterns of energy and information** in tridimensional **space**. The formation of **matter** from **energy** in the **evolution of universe**, the spontaneous formation of condensation **structures**, the formation of **dissipative structures** in **chaotic attractors**, the spontaneous synthesis of inorganic molecules, the generation of living **organisms**, the evolutionary increase in the number, **diversity and complexity** of species, the **development** of varied social cultures, and the psychological processes of individuation – all illustrate the spontaneous creation and destruction of **structures** through a multiplicity of different processes" (1994, p.1485-7).

The SABELLIs also propose a way to introduce mathematical **methodology** in P.T.: "It is convenient to express P.T. in more abstract terms: all natural and social processes are high dimensional transient complexes created by the **interaction** of pre-existing and universal low-dimensional **patterns** (cosmic forms). Being universal, these cosmic forms have numerical, geometric, algebraic, physical, biological and psychosocial **representations**: (0) zero order, **random** statistical **distribution**, quantum flux, genetic chance, luck; (1) oneness, unidirectionality, **symmetry**, **asymmetric** ordering relation (**lattice** theory), temporal flow of **time**, **energy**, life and history, social and psychological **asymmetries** and **hierarchies**; (2) twoness, opposition, **group** inverse, particles and anti-particles, two-valued **information**, sexes, complementary social **roles**, love-pairing; (3) triadicity, trifurcations, tridimensional **matter**, **structures**, tripartite **organization** of color **perception**, and of social mental **models**, and periodicities of order three that generate **chaos** (YORKE and LI). These simple processes interact with each other to create higher dimensional processes and thereby novelty, diversity, **complexity** and individuality (diversification). The numeral description of these forms may correspond to the **FIBONACCI series** (0,1,2,3,5,8, etc.) found in biological processes and in aesthetic **choices**... In summary, P.T. postulates a **hierarchical embedding** of changeable multidimensional **structures (topology)** (as contrasted to **attractors** which are conceived as mutually exclusive **patterns**) hence processes have a **self-similar fractal geometry**" (Ibid).

Process theory has obvious philosophic pre-socratic undertones (HERACLITUS, PYTHAGORAS and EMPEDOCLES), as well as Hegelian ones. Even if some P.T. concepts could seem controversial, it is however also solidly founded on a wide experimental basis in biology applied to medicine, psychology and psychiatry (in SABELLI's more specialized work).

SABELLI himself has assessed P.T. as a **general systems theory**: "Process theory was born as a bridge between biological and psychosocial medicine, highlights its continuity from HERACLITUS to PRIGOGINE, and makes the confrontation of multiple hypothesis, rather than the single-minded pursuit of one... P.T. differs from other G.S.T in three basic issues: (a) The existence of **boundaries** selecting the kind and **rate of inputs and outputs** has been considered a fundamental aspect of the definition of system. P.T. conceives also of **boundary-less** systems such as the solar system. Each entity has a **set** of entities interacting with it; thus each person is the center of her or his social **network**; obviously such **networks** overlap, have no **boundaries**, and include entities which do not directly interact with each other. (b) Organic **models** of systems highlight the **integration** of opposing **parts** in a totality, whereas P.T. gives equal importance to harmonic **integration** and **conflictual competition** and struggle. For instance, instead of viewing family and institutions as **subsystems** of society, P.T. views nation, places of work, families as mutually **synergic** and mutually competitive and conflictual systems which include each person. Even biological **organisms** are not simply **homeostatic** systems maintained by harmonic **interactions** among their component **parts**, but include processes that necessarily lead to death. (c) The **hierarchy** of systems has been defined in terms of **size** (subatomic, atomic, molecular, **organismic**, planetary, solar, etc.), using the **analogy** of Russian dolls or Chinese boxes. This scheme splits the physical **level of organization** and places social processes above psychological ones. P.T. postulates that **interactions** between **levels of organization** are organized by their historical **priority** and their **informational complexity** (mathematical, physical, chemical, biochemical, biological, social, psychological, spiritual); hence **social systems** are considered to have historical **priority** over psychological **organisms**, while personal processes are recognized as more complex than social processes... (But) the **biosphere**, the **population**, the **social system**, have **priority** over the individuals they contain. Systemic causes have **priority** over individual processes. The **complexity** of the system is *less* than the **complexity** of anyone of its individual **parts**; likewise a mechanical system is simpler than its atomic **structure**. In summary, P.T. views **structures** and systems as transient **developments** within processes, rather than viewing processes and **structures** as complementary aspects of systems" (1991).

P.T. is completed in psychosocial science by a Process method, based on what SABELLI calls "**action graphs**", i.e. paper and pencil diagrams of interpersonal exchanges of **energy**

(labor), **information** (about self and others, affection, entertainment, practical, social and intellectual skills) and **matter** (money and property).

2657

PROCESS THERMODYNAMICS²⁾ – 5)

H. SABELLI reconsiders thermodynamics from the viewpoint of process theory: "According to **process theory**:

(1) Everything is **action**, the **asymmetric flow of energy in time**. (2) Every action is associated with an opposing process, thus generating **symmetry**; the **maximization of entropy** represents this tendency toward the generation of **symmetry**. (3) Processes create **structures** (partial **symmetries**) at critical and intermediate values of temperature and dimensionality. Postulating that **asymmetry** and **symmetry** are cosmic forms that order all natural processes and **structures**, **process theory** provides a reformulation of **entropy** as **symmetry** rather than **disorder**, and of its **maximization** as a cosmic **asymmetry**. The tendency of processes to attain a more stable **configuration** creates **symmetry** in natural systems. The various forms of partial **symmetry** attained include not only more uniform and probable **distribution** of the system **components**, but also the formation of complex and **asymmetric structures**. **Entropy** thus increases everywhere, and faster in a **complex system** than in its simpler **environment** (1994, p.1484).

In other words, **order** and **disorder** are opposed, but complementary, a concept formulated by SABELLI under the term "**enantiodromia**".

As to **maximization of entropy**, considered as reflecting growing **symmetry**, it is supposed to mean that total statistical **disorder** (in a gas for instance), should be equated with maximum **symmetry**, i.e. the inexistence of significant **asymmetric** features.

In accordance with PRIGOGINE's **thermodynamics**, it would be advisable to speak of increase of **entropy production** in **complex systems**, and not merely of **entropy**.

2658

PROCESSES (A taxonomy of)¹⁾ – 2)

This is no more than a tentative taxonomy based on different descriptions of processes made independently by various authors.

- **Causal process**: "A process such as, if the **state** of system is exactly known in a given moment, it becomes possible to univocally determine its **state** in a future instant".

This definition by V. TONINI (1971, p.227), related to Laplacian view of determinism, is obviously theoretical. While all processes are necessarily causal, their **perfect knowledge** at any moment is impossible.

- **Chaotic process:** A process proper to any **complex system** with **sensibility** to its **initial conditions**.

A chaotic process remains basically **deterministic**, but its development is not precisely predictable, as it turns generally probabilistic, within fuzzily determined **channels**.

- **Cybernetic process:** "A process submitted to **regulations** aiming at the elimination of unfavorable probabilities and optimize the favorable ones" (TONINI, p.229).

This is the classical **control** process of N. WIENER.

- **Cyclical process:** A process in which interconnected, but different regularities lead to **periodic oscillations**.

This type of processes is a typical result of any **endogenously** or **exogenously** generated **constraint**. There are various types of cyclical processes, as:

- cyclical with progressively **damped oscillations**, resulting from the dominance of the **negative feedback** over the positive one. It may lead to the destruction of the system by blockage.

- cyclical with progressive **amplified oscillations**, a result of the dominance of the **positive feedback** which can lead to the destruction of the system or to **dissipative structuration** and the possible **emergence** of a more **complex system**.

- **Ergodic process:** A succession of **states** of a system which depends directly from its most recent **state**, but also in a stochastic way from a **transitions** probability **matrix** which reflects the more or less lax general **constraints** on the system.

- **linear process:** A **monotonous** process in which a same quantitative cause produces a same corresponding quantitative effect.

- **logistic process:** A process in which a first **period** of **nonlinear growth** is succeeded by an also **nonlinear** decelerating **period**.

A logistic process can lead either to an asymptotic **limit**, or to a more or less strong **relaxation oscillation**.

- **nonlinear process:** A process in which an accumulative cause (geometric, exponential, hyperbolic or logarithmic), or a **feedback** leads to non-monotonous increasing or decreasing **effects**.

If not **regulated**, nonlinear processes lead to deep **changes** in systems and, sometimes to their destruction or **mutation**.

- **Stochastic process:** "A process that produces a series of **symbols** in accordance with certain probabilities" (C. SHANNON, 1949).

Replacing "**symbols**" by "**effects**" this **communication theory** definition can be considerably extended.

Stochastic processes allow for global **forecasts**, but not about any specific determined **behavior**.

- **Undetermined process:** "A process for which no perfect **knowledge** of the original **state** of the system is possible" (TONINI, p.228).

2659

PROCESSING (Parallel distributed)²⁾

The simultaneous processing of numerous different **data** in different **parts** of a **network**.

Such seems to be basically the way the **brain** does process the sensorial **inputs**. While a digital computer works at a pace measured in billionths of seconds, neurons work at the pace of merely thousands of seconds. But in about a tenth of a second, the **brain** recognizes anyone of a fabulous number of features of many kinds. This is a result of teamwork among groups of neurons *sharing* parts of the task. This is the basis of **connectionism**, whose concepts are now applied with increasing success to build the so-called **connection machines**.

2660

PROCESSING: Simultaneous or sequential²⁾

In common computation, processing is sequential. It: "requires that both **data** and instructions be encoded into notation" (F. FRISCHKNECHT and J.P.van GIGCH, 1989, p.245).

Symbol manipulation of this kind does not allow for **autonomous behavior** of the **artefact**. Moreover, it tends to be **dichotomic**, opposing **state** and **process**, as observed by the cited authors.

For example: "In A. I. we have a **state language** and a **process language**. In psychology **knowledge** is contrasted with **learning**, **memory** with **cognition** and imprinting with constructing. And systems have **states** and an **evolution process**" (p.246).

The authors explain many other implications of the **dichotomic** character of our processing **artefacts**.

Comparing the computer and the **brain**, as **data** processing devices, J.von NEUMANN wrote: "... the natural componentry favors **automata** with more, but slower **organs**, while the artificial ones favors the reverse arrangement of fewer, but faster, **organs**. Hence it is to be expected that an efficiently organized large natural **automaton** (like the human nervous system) will tend to pick up as many logical (or informational) items as possible **simultaneously**, while an efficiently organized large artificial **automaton** (like a large modern computing machine) will be more likely to do things successively..." (1958, p.50-51).

von NEUMANN expressed this at his Silliman lectures in 1956. The basic idea is still valid, in spite of the fabulous progress in computer's hardware. However, it seems now quite possi-

ble that the future **connection machines** will mimic more and more efficiently our "large natural **automaton**"... with results which are anybody's guess.

Finally, the universal problem seems to be: how to obtain complex and **integrated** thinking out of the basically **binary** processing, both in the computer and in the **brain**.

M. BODEN understands that there are basically two types of thinking; the "sequential-deliberative" and the "**parallel-intuitive**" (1990, p.205). The first one would be monotonically **time-ordered** in **linear** sequences, while the second one would be moreover multi-**simultaneous**.

BODEN adds: "By means of **parallel** processing of various kinds, human minds are well suited to have **serendipitous** ideas" (p.220).

2661

PROCESSOR²⁾

A device that operates a specific **transformation** within a system or an exchange between the system and its **environment**.

This notion, introduced by J.L.LE MOIGNE, corresponds approximately to the concept of **critical subsystem** of J.G. MILLER and somewhat less so to J. FORRESTER's **gates** (1973).

LE MOIGNE states: "The elemental processor can be identified in a general way by various characteristics whose definition shall frequently guide the **model** builder: In "*extensity*", it can be recognized by its **capacity** (of **storage**, transportation, production) or its **power**; in "*intensity*" by its **output**, or its **level**, or its **efficacy**, or its **yield** (a numerical relation between the **output** and the **input** at a given moment), or by its **efficiency** (a relation, possibly even qualitative, between its observed **behavior** and the hoped for **behavior**)" (1977, p.79).

LE MOIGNE observes that: "A priori an elemental processor may well process various kinds of **flows**: various **inputs** and various **outputs**. It may also be affected by different **fields**, which may influence the **stability** in time of its **behaviors**" (Ibid).

2662

PROCESSORS (Set of the)²⁾

According to J.L.LE MOIGNE, the **set** of the processors of a system composes a **net**, whose **connections** can be figured by a **graph** or represented by a square matrix (1977, p.87).

The processors' **net** makes up the **structure** of the system and its graphical and matricial **representations** permits its structural analysis.

LE MOIGNE sorts out the internal processors of the system as opposed to those which connect it with its **environment**. These last are of two different kinds: the **sources**, which in the **model** have no **inputs** and the **sinks**, which have no **outputs**.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

LE MOIGNE's "**Système général**" is a "net marked off in an **environment**".

2663

PRODUCER^{1) - 2)}

"The **subsystem** which forms stable **associations** that endure for significant **periods** among **matter-energy inputs** in the system or **outputs** from its **converter**" (J.G. MILLER, 1978, p.3).

This is one of the 20 **critical subsystems** in MILLER's **taxonomy of living systems**.

MILLER adds: "... the materials being synthesized being for **growth**, damage repair, or replacement of **components** of the system, or for providing **energy** for moving or constituting the system's **outputs** of products or **information markers** to its **suprasystem**" (Ibid).

Clearly, "producer" is a generic term covering many types of specific or specialized producers.

2664

PRODUCT INHIBITION^{1) - 4)}

The **situation** in which one or various products of the system's **processes** finally impedes these **processes**.

The **model** for this situation is the inhibition of a chemical reaction by the very products of the reaction.

This seems however to be only an example of a very general systemic **phenomenon**: the inhibition takes place because the product saturates either the **environment** or the **invironment** of the system by suppressing some indispensable condition for the **process**.

Product inhibition implies a strong warning for **human systems**.

2665

PRODUCTION^{1) - 2)}

Any process of **transformation** within a system or **subsystem** that leads to the creation of new **elements**, usable for other **subsystems** or systems.

The production **processes** are clearly described by J.G. MILLER in his "**Living Systems**" (1978).

Production should be regulated as closely as possible to the needs of the users **subsystems** or systems in order to avoid squandering of **resources**, or either **overload** or **underload** of the producing and the receiving systems.

2666

PRODUCTIVITY as a systemic concept¹⁾

As noted by R.O. MASON, the common concept of productivity is, from a systemic viewpoint quite questionable. It may refer to some material **outputs** of the system, or to some services

the system offers to other systems, or in some cases to its own overall **efficiency** or even its **survival capacity**.

According to MASON: "Systemic productivity questions the **design** of the system itself: Is it living up to its maximum feasible potential? Is it doing what it ought to do to develop its **resources** and to pursue opportunities? In a disturbed, reactive **environment** these are the salient questions" (1979, p.17).

MASON moreover distinguishes between:

"**Systemic output productivity** (as) the ratio: Actual **output** divided by the maximal **output** that could be produced by the best alternative, feasible, designable and importable system of the same class", and...

"**Systemic input productivity** (as) the ratio: Minimal **input resources** that are required to produce a given **level of output** by the best alternative, feasible, designable and importable system of the same functional class divided by the actual **input resource** consumed to produce that **level of output**" (p.27).

MASON concludes: "Systemic productivity is an indicator of the long-run **survival** and **viability** of the system" (p.28).

The systemic **concept** of productivity is thus very close to **thermodynamic efficiency** of the productive system and should not be reduced to the idea of maximum possible productivity.

2667

PROGRAM^{1) - 2)}

1. "A **set of code signs** that indicate the **actions** to be performed by a **living system** or an **artefact** in order to achieve its **purpose**" (J.Z. YOUNG, 1974, p.297).

J.Z. YOUNG adds: "In **living systems**, the aim is the continuation of the individual and/or his programs" (Ibid).

Programs are ordered in the **time** dimension: their execution is sequential. Moreover, at least **parts** of the program are recurrent, which leads to **autopoiesis** and **hypercycles**.

The future development of a complex program is somehow **implicit**: **complex systems** are **self-organizing**. This is true only – at least until now – for **living systems**. It seems however that **self-organization** starting from a **set** of rules is now becoming a feature of some **artifacts**. See: "**Connection machine**".

In **living systems** the **combinatorics** implicit in the program is unavoidably limited, even if it may be very great. This may be setting **limits** to **learning** and even to the lifespan in **living systems**.

2668

PROGRAM (COMPUTER)⁵⁾

"A list of statements or instructions in a special purpose programming **language** that directs a computer to undertake a certain computer task" (K. KRIPPENDORFF, 1986, p.61).

In fact, such a program is a more or less complex **algorithm**.

T.ÖREN writes: "A computer program is a **knowledge transducer** similar to any **energy transducer**. A computer program has an **input knowledge** and an **output knowledge**. A **knowledge transducer**, i.e. a computer program, can do three types of **knowledge** processing:

- 1) It can **transform** its **input knowledge** into **output knowledge**.
- 2) It can provide **knowledge** about an **input knowledge**, and
- 3) based on an **input** (a query for example), it can process some **knowledge** that exist in a **knowledge base**, to provide an **output knowledge**" (1990, p.13).

For the use of the word "**knowledge**" instead of "**information**" see B. ZEIGLER comments under "**Knowledge**: a pragmatic and operative views".

2669

PROGRAM (Developmental)²⁾

A type of constructive **set of rules** that leads to development by variable **interactions** between the rules and in relation to variable external conditions

It is becoming clearer with time that no **complex adaptable system** can be rigidly programmed, i.e. that it cannot be constructed using an **algorithm** – even a very complex one.

This corresponds to the very need for **adaptability** to continually changing conditions. It could be the basic significance of the construction of complex entities (biological, social) "**by trial and error**" and in accordance with the **bottom up model**.

It is now widely admitted that the classical so called "**artificial intelligence**" based on complex programming (for ex. chess programs for computers) lacks the basic adaptability of **human intelligence**.

→ **Artificial Life; Homeobox; Parallel distributed processing**

2670

PROGRAM (Inductive)^{2) - 5)}

A program using "a purely logical approach to find abstractly defined regularities in the **data**, irrespective of subject-matter" (M. BODEN, 1990, p.186).

M. BODEN states: "A **learning** program that uses this logical strategy can structure a "**classification-by-property**" **conceptual space** in the most economical way, and can find the shortest pathway for locating examples within it... The program defines not only the relevant search-tree but also the most efficient tree-search. It learns to ask the right questions in the right order, so as to decide as quickly as possible".

¹⁾general information²⁾methodology or model³⁾epistemology, ontology and semantics⁴⁾human sciences⁵⁾discipline oriented

This type of programs is now used in **expert systems**.

2671

PROGRAMMED CONTROL

→ **Control (Programmed)**

2672

PROGRAMMED INSTRUCTION¹⁾ – 5)

"A technique for presenting a subject matter to a student who can work through it at his own **learning speed**" (K. KRIPPENDORFF, 1986, p.59).

KRIPPENDORFF describes it as "... a **network** of statements and tests, which direct the student to new statements depending on his **pattern of errors**" (Ibid).

The technique is useful, specially when applied to precise formal errorless **data** systems. But it supposes that the programmer rigorously channels the student's **training** (no sidelines!, no critique other than the one implicitly included into the program!). And it supposes that the student is sheepishly disposed to navigate the programmed **channels**. Finally, it implies a SKINNERIAN **behavioristic** concept of **training** by conditioning.

2673

PROGRAMMED LEARNING¹⁾

A more embracing and open training **method** to teach appropriate **knowledge** to individuals, "aimed at the right **level**, sequential and logical and entirely compatible with the **objectives** and intentions of the individual and the **organization**" (After I.G. BLOOR, 1987, p.43).

BLOOR states that some years ago "self-paced material was developed to enhance **flexibility** and **choice** in the form of specially written texts that included self-**assessment**. Today's equivalent of this training technique is known as Open Learning which offer the **flexibility** of self-paced study with the additional support from an internal or external (e.g. a college) trainer" (Ibid).

From a systemic viewpoint, the crux of the matter is the *quality of the content* of the offered texts, which should be oriented to an integrated vision of what is to be learned, in order to broaden the **understanding** of the user.

2674

PROGRAMMING⁵⁾

A **procedure** aimed at solving some type of problems on base of existing **data** and fixed **rules** to process them, and ordering the presentation of results.

This is mostly done by using computers, with adequate programming **languages**.

It should however never be forgotten that programming is a tool at the service of **management** and **planning**, which means:

- that it should correctly reflect the **goals** pursued by the overseers
- that, once the first condition satisfied, it cannot be held responsible for conceptual **errors** of managers or planners.

2675

PROGRAMMING (Dominant)²⁾

The **top-down** construction of a program in **artificial intelligence** research.

C. EMMECHE explains: "The total **behavior** is programmed a priori by dividing it into strictly defined subsequences of **behavior**, which are in turn divided in **subroutines**, smaller **subroutines**, etc., all the way down to the **program's own machine code**". (1994, p.19)

It could be argued that the **top-down method** has engaged classical **artificial intelligence** into a dead-end, because it precludes any possibility of non-programmed **adaptability**, **creativity** or **emergent behavior**.

EMMECHE implicitly makes the point, adding: "The **bottom-up method** in **artificial life** imitates or simulates **processes** in nature that organize themselves" (Ibid).

This means that **artificial life** cannot be simulated or created by dominant programming.

2676

PROGRESS¹⁾ – 3) – 4)

The advance towards a positively valued **goal**.

This is a heavily **value**-loaden *concept* which should be considered carefully from a systemic viewpoint.

To begin with, progress should not be confused with progression or increase of quantitative values. Such an increase is normal in immature systems developing along **chreods** until they reach their normal **homeostatic** grown-up **level**. It would turn pathological once such **homeostatic state** has been attained. This, at least, is the case for **living systems**, but altogether probably for social ones.

However, quantitative increase may conceivably lead to qualitative progress, if one admits that **structuration** by **dissipation** in systems **far- from- equilibrium** can lead to a higher **complexity level**.

This view may explain why our materially exploding culture equates so generally progress with quantitative increase (that seems in fact to increase **complexity**). However, there are some **processes**, as for example exponential supposedly limitless **growth**, or non-compensated **positive feedback** that may easily lead to the demise of the system by exhaustion of its **environmental sources** or massive **overburdening** of its **environmental sinks**.

Thus, progress should not necessarily be identified with **growth** or increase. We should also make ourselves aware of our cultural prejudices as members of a techno-economical based culture, which could very well be preparing for itself some serious **problems** generated by its own success.

2677

PROPAGATION¹⁾

The spread or dissimulation of some characteristic in a **population**, or between **elements** or **subsystems** in a system.

Propagation is possible only if the characteristic is **adaptive**, or at least not counter-adaptive. It is quite generally limited because no **environment** can support the unlimited **growth** of any type of system. Excessive propagation of some **population** normally leads to a crash.

This may also be the case for techniques, ideas (**memes**) and the like, a subject that would be useful to research.

From another viewpoint, propagation is never instantaneous and quite unfrequently **isotropic** and/or **isochronic**. As the basic interaction mechanism, it can be **linear** or **nonlinear**, in this case with different types of **feedbacks**, on different **rhythms** in **time**. It can also take place in **hierarchical levels**, between **components**, or **clusters of components**, organized or not in **subsystems**.

The **simultaneous** propagation of various **effects** within a system can lead to more or less **deterministic chaos**.

See for example J.C. ECCLES about propagation of impulses within the cerebral cortex (1977, p.201-2).

Propagation **modes** are also of great importance in **human systems**.

→ **Criticality; Percolation**

2678

PROPAGULE¹⁾⁽²⁾⁽⁵⁾

A reproductive **element** able to migrate far away from its original **population** or system.

L. PITELKA et al. use the term in botanical **ecology** (1997, p.467).

Seeds carried away by strong winds, or transported by vertebrates are classical examples.

Propagules frequently play an important role in dispersal and expansion of **epidemics** through new and widely scattered foci. A recent example is intercontinental AIDS **propagation**.

Another example is the explosive expansion of forest or bush fires by sparks or burning twigs carried away by fire storms in conflagrations.

Propagules are probably a condition, or at least a very significant factor in **percolation phenomena**.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Accordingly and in an extended **meaning**, reproductive **elements** of any kind as for example bacteria, books, fashions, slogans, **memes**, etc. can be considered propagules.

2679

PROPERTIES (Systemic)^{1) - 2)}

The French systemist B. WALLISER proposed the following properties as characteristic of systems:

Diacronic properties: "Set of the **relations** among the various characteristics of the system at successive moments" (1977, p.73).

Synchronic properties: "Set of the **relations** among the various characteristics of the system at the same moment" (p.73).

In a system both **synchronic** and **diachronic** properties must be permanently non-contradictory.

Emergent property: "Any new property of the system that is not a property of any of its **sub-systems** or **elements** and is essentially due to the characteristics of the **net** of their **interrelations**" (p.47).

Immergent property: "Property of some **subsystem** that cannot anymore be found at the **level** of the system" (p.47).

Both types of properties can be synthesized as follows: "A system is at the same time, more and less than the sum of its **parts**".

2680

PROPERTY and FUNCTION¹⁾

F. BONSACK emphasizes the necessity to clearly distinguish "property" from "function". He writes on the topic:

"Some biochemist say: "To fix oxygen is a **property** of hemoglobin. To say that it is its **function** does not add anything, if not a finalist connotation, that should be eliminated from modern science..."

"It is true that, *when we isolate* hemoglobin, it has only properties. A property characterizes an isolated substance, it is tied to this substance. To speak of "function" has no sense here. The function is no property of the chemical substance, it is a property of the functional **organization** of the **whole**. The **property** of hemoglobin to fix or to liberate oxygen is used by the function "transport of oxygen from the lungs to the tissues".

"The function is not tied to the chemical substance (just as it is not tied to a person who occupies some post in an **organization**). The proof of this is that *another* substance (or another person) may act in the same function. Conversely, the same substance (or person) may perform different functions in the same **organism** (or **organization**) or in a different **organism**" (1989, p.23-4).

2681

PROPERTY (Emergent)→ **Emergent properties**

2682

PROSPECTIVE^{1) - 4)}

The French name for scientific **forecasting**.

Prospective has been introduced in France by G. BERGER (1964) and considerably developed by the "FUTURIBLES" group under the leadership of B.de JOUVENEL. Its conceptual foundations have been researched by Ch. FRA-NÇOIS (1976).

Its spirit is quite different from American futurology, albeit closer to English futurics as reflected in the journal "FUTURES". It is more concerned by the **validity limits** of any proposed **forecasts**.

It has also a higher level of insight in relation to **complexity** in **nonlinear systems**, avoids linear **extrapolations** and remains generally wary about *any extrapolation*. It is thus more concerned by **systemics** than futurology is. This stand has been considerably reinforced in the recent years with the development of **deterministic chaos**, which infuses a salutary skepticism about so many pseudo scientific "**scenarios**".

Prospectivists are also generally aware of the traps of the voluntarist illusions of some managers who lack clear ideas about the **interactions** of the system they govern with its complex **environment** and remain prone to ill-advised, **short term** and superficial tinkering.

2683

PROTOCOL²⁾

A register of the successive **states** of a **variable**.

ASHBY introduced this notion in relation to the **black box model**. He wrote that the protocol could "... be regarded as a **message** that contains **information** about the box's nature" and added that "... the investigator's **knowledge** about the box, in any of its aspects, must be essentially a recoding of what is in the protocol: he may not claim more.

"From this point of view, to discover something about the **black box** – something that has permanence – is to discover a **constraint** in the protocol" (1958, p.201).

2684

PROTOCOL (Compacting a)²⁾

According to ASHBY: "The study of a system can thus be summed up in a few words: to discover the **constraints**, the statistical **structure**, in the protocol" (1958, p.201).

This is possible only if the protocol does not show absolute **randomness**, but on the contrary contains a certain amount of **redundancy**.

In this case, "... a recoding of the **redundancies** (or **constraints**)" (Ibid) permits a degree of "compacting" of the protocol and the discovery of some more or less permanent "**property**" of the system. This **procedure** permits the elaboration of simpler **messages** that contain all the **information** included in the protocol, but without **redundancy**.

2685

PROTOFUNCTION²⁾

The **structure-shaping** effect of some new **components** whose **interactions** may lead to the **self-organization** of a system.

This concept has been introduced by V. CSANYI (1989, p.78) and is related to his **replicative selection** and **zero- system model**. CSANYI states: "The protofunctions are formed at **random** in the **zero-system**. Certain conditions for the **emergence** of the **cyclic organization** of these protofunctions and the existence of completely reproducing chemical **networks** (RCN), have been found by KING (1982, p.85-87)".

2686

PROXEMICS¹⁾⁴⁾

"Man's use of **space** as an aspect of his **culture**" (E.H. HALL, 1977, p. 248)

This notion includes "conversational distance, **planning** and use of interior **spaces**, town layout and the like"(Ibid)

HALL's concept is rooted in what he calls the "intrusion **distance**" which is related to the physical and psychological **reaction** of an individual who feels discomfort, anger or anxiety when his/her "personal space" is invaded.

This is somehow the opposite of critical proximity (see hereafter). It seems however that, in human beings also, critical proximity may produce a sudden change of **behavior**, transforming them upon a critical **threshold** from individuals into **elements** in a **crowd**.

According to HALL, members of distinct **cultures** have slightly different ways to perceive critical proximity.

An intriguing point is the possibility that the strong social compression that results from the planetary **population explosion** during the 20th C. could lead either to unbearable psychological **stress** among people or contrarily to the general acceptance and tolerance of a reduced intrusion space.

The historical consequences for the whole of mankind could, in both cases, be impressive.

N. ORT gives another interesting definition of proxemics: "The **semiotic** aspect of territory in non-verbal **communication**" (2001, p.153). This clearly implies that proxemics has its roots in animal behavior.

2687

PROXIMITY (Critical) ²⁾

The distance **limit** over which **components** cannot anymore interact.

Critical proximity is generally determined by converging **exogenous** forces. **Interactions** can however also start when masses of loose **elements** start to converge (in a proto-star f. ex.) or when their **density** increases over a **critical threshold** (in locust **swarms**, in **Dicystostelium discoideum**).

In such cases, a self-maintaining **process**, corresponding to **organizational closure**, is initiated, which will last for the whole **life-time** of the system or society.

→ **Positional value; Proxemics**

2688

PSYCHOLOGY (Ecological) ³⁾

This is a concept coined by the American psychologist J.J. GIBSON (1986).

Ecological psychology recognizes the **co-evolution** of animals and their **environments**, and pursues a principle of animal-environment reciprocity as its basic guideline.

This has been a reaction against two opposite extremes: pure mentalism that divorces the animal's **behavior** from **environmental constraints** and **behaviorism**, which trivialize its reactions to the **environment** at a too simple **habituation** and conditioning level.

→ **Perception (Ecological)**

2689

PSYCHOLOGY (Genetic) ³⁾

As observed by E. ANDREEWSKY, PIAGET's genetic psychology's basic concepts are closely related to systemic ones. She writes: "A child builds his own intelligence by means of his **interactions** with both his inner biological **environment** (maturation of the nervous system) and his outer physical **environment** (his actions on **objects**) as well as his social **environment** (**language**, **cooperation** with adults and other children). The **interactions** between these **interactions**, which PIAGET calls *equilibration*, is the means of organizing this **set of interactions** into a system" (1993, p.187).

ANDREEWSKY also relates VIGOTSKY's Social Interactionism with PIAGET's social accommodation (p.188).

2690

PSYCHOLOGY (Systemic) ^{3) - 5)}

von FOERSTER's **Cybernetics of 2nd order** and, later on MATURANA and VARELA's concepts of **autopoiesis** and **organizational closure** have deeply modified the stand and viewpoints of a number of psychologists.

Some of them now admit that they should be careful, lest they instill their own views into the psychological or psychopathological **situation** they have to consider, with a serious risk to distort it.

In effect, psychology's endeavor is "the **evaluation** of human systems by evaluatory human systems" (R. GLANVILLE, 1979, p.37)

Indeed, "The actions of an (experimenting) **observer** are **actions** involving **control** and **communication** between the **observing** and the observed system" (ibid, p.37). We thus should speak of "a reflective and reflexive psychology" (ibid)

A powerful movement of "systemic psychology" has surfaced in Argentina, possibly too exclusively related to the **autopoietic model**, not considering enough other systemic and cybernetic **concepts** and **models** that could be of interest in psychology.

2691

PSYCHON ^{3) - 5)}

"Any neural unit capable of discharging mental **functions** of some kind" (M. BUNGE, 1979, p.128).

BUNGE, who introduced this neologism, states that "there are three main views concerning the nature and size of psychons: neuronism (sic), **holism** and systemism. According to neuronism single neurons may possess certain mental abilities – e.g. that of issuing **commands**. There is no evidence for this view. Holists, on the other hand, assume that nothing short of the whole **brain** can mind: they speak of "mass action" and favor **holographic** theories of **memory** and other mental **functions**. Although there is plenty of evidence for the strong coupling among a number of **neural** systems, there is also evidence for **localization** of, e.g., pleasure and speech.

"So we are left with *psychosystemism*, or the hypothesis that the **brain**... is a system of specialized **subsystems** or **organs**, some of which are itinerant rather than fixed. There is multiple evidence for psychosystemism, so we shall adopt it" (p.128-9).

BUNGE's neologism has not spread much and the negative aspects of his views may still not be generally accepted.

2692

PSYCHOSOMATIC NETWORK ⁵⁾

The globally integrated network that interconnects the **nervous system** with the endocrine system and the immune system

The existence of this global network has been established by C. PERT and results of the general action of about 60 to 70 different peptides which act as messengers and mediators between the more specifically acting systems

In the words of F. CAPRA, who offers a synthesis of PERT's research the "conceptual separations are merely historical **artifacts** that can no longer be maintained" (1997, p. 282)

2693

PURPOSE ^{3) - 5)}

"The aim or **objective** of a **living system** (or artefact) as indicated by the standards embodied in its **program of controls**, including those standards acquired by **learning**" (J.Z. YOUNG, 1974, p.297)

This definition by-passes the willfulness problem, at least in the case of most **living systems**, since most of them have no possibility of **control** over their own **program**.

However, in their 1943 foundational paper about "**Behavior, purpose and teleology**", A. ROSENBLUETH, N. WIENER and J. BIGELOW wrote: "The basis of the concept of purpose is the awareness of "voluntary **activity**"... The term purposeful is meant to denote that the **act** or **behavior** may be interpreted as directed to the attainment of a **goal**, i.e., to a final condition in which the behaving **object** reaches a definite **correlation** in **time** or in **space** with respect to another **object** or **event**. Purposeless **behavior** then is that which is not interpreted as directed to a **goal**".

And: "... the purpose of voluntary **acts** is not a matter of arbitrary interpretation but a physiological fact. When we perform a voluntary **action** what we select voluntarily is a specific purpose, not a specific movement" (1943, p.19).

These authors also state: "All purposeful **behavior** may be considered to require **negative feedback**. If a **goal** is to be attained, some **signals** from the **goal** are necessary at some **time** to direct the **behavior**".

These quotations call for some remarks;

1. Are **living systems**, or **artefacts** "**goals**" to be distinguished, and if so, how? The **goal** of a **cybernetic artefact** is introduced by its builder. However, once there, it becomes an **autonomous** feature of the **artefact**.

2. Is the presence of a **negative feedback** always a **signal** of the existence of a "**goal**", or "purpose"?

3. **Goals** are, by necessity, the **present representation** of a **state** to be attained or maintained. There is thus no paradox about a supposed influence of the future upon the present.

G. PASK distinguishes "purposes for systems", as the **function** we assign to them within some larger **context** and "purposes in systems" as the internal **goals** driving their **behavior**. He adds that "... we cannot make sense of a system without assuming a purpose for or in it thus all systems are **purposeful**" (1969 – as quoted by W.R. WINBURN, 1991, p.555)

Or course, such assumptions are "ours".

As to the purpose of **artifacts**, until now at least, it is strictly defined by their constructors. An intriguing question would be to define the possible purposes of **artifacts** which would "acquire standards by **learning**".

J.van GIGCH offers a **context** view of purpose: Inanimate systems are devoid of visible purpose. "They acquire a specific *purpose* or *function* when they enter into **relationship** with other **subsystems** in the **context** of a larger system" (1978, p.14). Purpose has thus a reactive character.

According to W.T. POWERS, "In a **control-system model**, a purpose is simply a **reference signal**. The reference signal determines the state to which an **input**, a sensory **signal**, will be brought and at which it will be maintained. In nearly all control systems, the sensory input represents the state of some external variable affected by the system's **action**. So whatever action brings the sensory signal to match with the reference signal performs brings the sensed external **variable** to some specific **reference state**" (from POWERS' internet page, 1999). This implies some internal **feedback** embedded within the control **level**.

Thus, what is meant by purpose in every specific case, is defined by the system's level of **organization**.

Consequently, the very diverse uses of the term may easily lead to **semantic** muddles and conceptual confusion.

On the other hand T.W. DEACON, in a 2001 review of G. CZIKO's book "The things we do" (2000), mentions that "According to POWERS, purpose is concretely represented as a perceptual **reference signal** in some internal **feedback loop** embedded in other higher order **feedback loops**"

→ **Finality; Teleonomy**

2694

PURPOSE in SOCIAL SYSTEMS ⁴⁾

The idea of purpose in social systems is a conceptual quagmire. At least three different viewpoints can be distinguished:

- 1) The one, more or less naive, of many leaders who believe that *they themselves* define the purposes of the system. What they really do is to try to instill *their own* purposes into it, i.e.:
 - what they believe the system could or should do; In this case they merely act accordingly to what they *think* they know about the system's nature;
 - what they want the system to do: In this case they act generally according to some **values** and **norms** that they received... from some part of the system itself, and they frequently do so quite unwittingly.

- 2) What the system *apparently* does: its members perceive merely what they were educated to see by **learning** or ideologic indoctrination: In this way, they are of course in for many surprises.

- 3) What the system *really* does, i.e. trying to survive, which implies many unexpected **behaviors**, whose **understanding** generally dawns upon the participants quite a long time after the **events** themselves.

D. KATZ and R.L. KAHN think that: "*It would be much better theoretically*, however, to start with concepts which do not call for identifying the purposes of the **designers** and then correcting for them when they do not seem to be fulfilled. The theoretical **concepts** should begin with the **input**, **output**, and functioning of the **organization** as a system and not with the rational purposes of its leaders" (1966, p.89).

Numerous systemic concepts and **models** could be used to study **social systems**, in accordance with J.G. MILLER's **methodology** and could lead to a new type of systemic sociology.

2695

PURPOSEFUL, Intentional, or willed ⁴⁾

"An **activity** which is purposeful becomes an **action**" (R. RODRIGUEZ ULLOA, Glossary, 1999)

2696

PURPOSIVE ^{3/4)}

"Describable by an **observer** as serving a purpose" (R. RODRIGUEZ ULLOA, Glossary, 1999)

If purposiveness depends on an **observer's** view, it becomes clear that different **observers** may have different - and even contradictory - views of the supposed **purpose** of the **action** they are observing.

This may be significant in any **model building process** and even generate **conflicts**.

2697

PYRAMID ^{2) - 4)}

A **hierarchy** wherein many subordinate **levels** are submitted to one **control level**.

W.D. GROSSMANN and K.E.F. WATT observe that, while "SIMON provided examples demonstrating why a **hierarchical** architecture increases the probability of reliable functioning... the **noise** to **signal** ratios increase in **messages** communicated between **hierarchical levels** as the number of **levels** increases (S. BEER, 1976). This means that it becomes increasingly difficult for the head of an **organization** to integrate and co-ordinate the **activities** of all **levels** and subdivisions within each **level**, as the number of **levels** increases" (1992, p.9).

The enormous problems suffered by some well known giant multinational enterprises is a neat proof of this.

Q

2698

QUALIA ^{1/5)}

The inner states of **perception** that we describes as qualities

Examples are the "blueness" of blue, or the "saltiness" of salt. The ways these inner states appear (and in specific cases become refined, as for ex. in the perception of shades of green by a painter) is still quite unexplained. It is however the bedrock of our inner **representation** of **reality** and the source of the **communication** ability between humans who are supposed to have equal or equivalent inner perception of "saltiness" or "blueness" or any other psychological **percept**

This subject has been extensively explored by G. EDELMAN and J. SEARLE, for example

2699

QUALITATIVE LAWS ^{1) - 2) - 3)}

Qualitative laws are generalizations of similar, but non-measurable properties. This is the basic mental **process** that leads to fundamentally new discoveries.

M. BODEN cites as an example: "The chemist GLAUBER (who) clarified the qualitative **distinction** between acids and alcalis, and between acids and bases (Bases include both alcalis and metals). He did so by classifying the experimental observations - including some produced in experiments he designed himself - in a logically coherent way. He discovered, for instance, that every acid reacts with every alcali to form a salt" (1990, p. 197-8).

H. SIMON and colleagues have designed a **program** named GLAUBER that modelizes the discovery of qualitative laws "by classifying things according to their observable properties" (Ibid).

Qualitative laws are frequently the first step to quantitative ones. A good example is MENDEL's quantification of inheritance laws, that were already more or less known in qualitative terms by plants and animals empirical breeders.

In a more formal domain, R. THOM observed that **topology** is basically a qualitative branch of **mathematics**. Qualitative mathematical **structures** are interesting, even if not measurable (1991, p.79).

2700

QUALITY CONTROL in Interactive Management ⁴⁾

This is not quality control of material products. As understood by J. WARFIELD, it concerns attitudes related to **management** and **planning**, as well as to **ethics** in general systemic terms. WARFIELD specifies five key concerns in this sense:

" Concern for the client
 " Concern for I.M. practitioners
 " Concern for I.M. participants
 " Concern for the reputation of I.M.
 " Concern for the society as a **whole**" (pers. comm.)

Only this generally concerned attitude can avoid local or global negative **side effects**, of which we observe a growing number of increasing gravity. Consequently, WARFIELD considers that "Unless all five concerns can be dealt with favorably in the particular **situation**, **activity** should be terminated" (Ibid).

A very difficult problem remains: How to diffuse these views in societies that do not care?

2701

QUANTITATIVE into QUALITATIVE ²⁽³⁾

(from statistics to quasi-systems - or **composite systems**; from **composite systems** to **markovian systems**, etc...)

New qualitative **behavior** seems to emerge from massive quantitative and interactive **behavior** of many **elements**. This old view of MARX and ENGELS is now reframed within the **criticality** and **percolation models**.

2702

QUANTUM HOLOGRAM (Non local)

→ Hologram (Non- local quantum)

2703

QUANTUM VACUUM ³⁽⁵⁾

"The **energy** substrate from which the material **universe** is taken to have emerged"(G. FARRE, 2000b, p. 25)

FARRE explains: "It is thought that elementary particles, e.g. quarks and electrons, are the consequences of the interaction of virtual particles created by local **fluctuations** of the quantum vacuum"(Ibid)

Of course: "How radiant energy, which is not localised, suddenly condenses in one place (e.g. as in a pair (of particles production) is a profound mystery..."

"Equally mysterious is the reverse **process**, whereby **condensed energy** dematerialises and radiates, as in the case of the annihilation of positronium into two gamma rays under conservative **constraints**"(Ibid)

More mysterious still is why any question answered in sciences generates a new question, generally still more difficult to answer, as if our brain-mind could only generate an unending spiral of riddles

→ Gödel's incompleteness theorem

2704

QUARTER POWER (SCALING LAW of)

→ Scaling (Law of quarter power)

2705

QUASI-PERIODIC ²⁾

Condition of a **process** or system which never repeats itself perfectly, but only nearly perfectly.

Quasi-periodicity is typical of **complex systems** and closely related to **chaotic determinism**.

Quasi-periodic **processes** or systems are never perfectly predictable. Their **behavior** can however be forecasted within more or less narrow **limits**. This kind of **predictability** has been called "**asymptotic predictability**".

2706

QUASI-SPECIES ^{1) - 5)}

M. EIGEN defines the quasi-species as a **population** of molecules of similar composition (1992).

The concept seems applicable to **homogeneous populations** in general.

Different quasi-species may have distinct rates of correct **replication** in different **environments** and in this way, they become subject to selective influences and start to diverge from each other.

2707

QUEUEING THEORY ⁵⁾

An **Operations Research** theory (and **methodology**) used for the study of the **effects** of congestion in waiting lines.

This can be done by using specific mathematics and computer **simulation**.

Congestion however is also a **cybernetic phenomenon**, which relates to **channels capacity**, **flows velocity**, **turbulence in flows** and **networks dynamics**.

2708

QUORUM SENSING ²⁽⁴⁾⁵⁾

A chemical signaling **mechanism** that bacteria use to find out if they are by themselves or one of a crowd (G. WATTS, 2003, p. 30)

More generally collective **reaction threshold** in a **population** signaling the onset of a common **behavior**.

It could very well be a fundamental condition of any socialized **behavior**. It seems to be the result of increasing **density**, the consequent reduction of interindividual distances and the increasing reciprocal **perception** of **signals**. These can be biochemical, physical, visual, or other.

J. MARCHANT reports an example observed by G. WEGRZYŃ on marine bacteria (2000, p.8)

WATTS explains: "Each individual secretes into the **environment** a low level of a certain chemical, for which it has surface receptors. The more bacteria that are around and pumping out this chemical, the higher its local concentration and the more the cell surface receptors are stimulated..."

"The quorum" part of the name reflects the bacteria's need to be present in sufficient numbers to make it worthwhile to behave in a particular way, just as a political meeting needs to be quorate to take decisions. The **decision** bacteria need to make is whether or not to turn virulent"(p.30)

The somewhat metaphorical and anthropomorphic way to describe this **process** does not detract from its deep systemic significance: it amounts to the discovery at a very elemental biological **level** of the same process of **socialization** through density of **interactions** that also shows in ants, bees or locusts **behavior**. And of course, the appearance of a superior level of interactions through **informations** systems of various type in human kind is still another example of this very general process. Its systemic (and **transdisciplinary**) meaning is obvious.

→ Co-orientation; Density (critical); Dictyostelium discoideum; Effects (mass-); Field (Social); Flocking ; Herd effects; Implosion; Organizer; Overcrowding; Pheromone; Proximity; School; Stigmery; Swarm

2709

RADIATION (Self-contained) ¹⁾

Evolutionary radiation, i.e. the appearance and **differentiation** of various new types from a common origin in **time**, is a feature of **evolution** in general, i.e. not only of living beings, but also of **artifacts** and human **organizations**.

Moreover new types retain most of the fundamental characteristics of the original type and, at least in **living systems**, no new fundamental types seem to have emerged independently since the beginnings of life. If the same is true for **artifacts** is debatable, because there seems to be a complex recombination of characteristics among types and even new independent beginnings (electricity, nuclear energy for example).

The general **representation** of the succession of types is accordingly a unique **tree** fractalized along the **time** dimension, that could be inscribed within an overall containing funnel form.

2710

RANDOM¹⁾

In G. BATESON words: "A sequence of **events** is said to be random if there is no way of predicting the next event of a given kind from the event or events that have preceeded and if the system obeys the regularities of **probability**" (1979, p. 30)

He adds "Note that the events which we say are random, are always members of some limited **set**" (Ibid)

Absolute randomness is either experimentally fabricated, for example by throwing dices, or a mathematical **model**. It has been discovered that **randomness** is generally merely relative in observed events and corresponds to **deterministic chaos** or **self-organized criticality**. Absolutely random events would be possible only in the absence of any **constraints**, internal or external.

2711

RANDOM ACCESS⁵⁾

In a computer the retrieval **process** of **data** from the **memory**, which does not depend on the **memory** address.

2712

RANDOM NUMBER²⁾

Any number that cannot be generated by an **algorithm** shorter than the number itself.

According to KOLMOGOROV, "...a number is random if the shortest **program** for calculating its **digits** turns out to be about the same length as the number itself". In other words, a random number cannot be compressed, i.e. reduced to such a **program** (D. MACKENZIE, 1999, p.45).

Of course, this leaves a doubt: A shorter **program** could possibly exist, but not being yet discovered by someone.

→ **Complexity (Algorithmic); Garden of Eden**

2713

RANDOM PHENOMENON^{2) - 3)}

"A phenomenon which associates in a common **structure** a **set** of elementary phenomena ("microscopic") and a **macroscopic** phenomenon, in such a way that the evolution of last one is conditioned by the cumulated effects of the former ones" (J. BONITZER, 1988, p.82).

BONITZER comments: "Such a definition probably seems strange... (it is that) it does not consider **probabilities** in the first place as elements of a **representation** (as if it were from a positivistic philosophical angle), but on the contrary the random phenomena themselves, as elements of a **reality**."

In other words, a random phenomenon is a sum of **events** or **behaviors of the same nature**.

In opposition with the individual **event**, the phenomenon is all-embracing at a more general **level** (and refers frequently to a system or a systemic **process**).

This view of randomness is coherent with **deterministic chaos**.

2714

RANDOM PROCESS^{1) - 2)}

The concept of random process is somewhat obscured due to the fact that the role of **time** (past, present, future) is generally not well understood.

P. VENDRYES states: "As an experimental example one can take the throw of a dice. This is a random process... It is datum of common experience that the throwing of a dice occurs in *two stages*. During the first stage the player makes a choice (a bet) of one of the six faces of the dice. These are therefore six simultaneous alternatives available to the player. This multiplicity of alternatives makes the process **indeterminate** and **unpredictable**. The second phase occurs when any one of the six faces turns up, so excluding the other five. *This exclusion makes it an irreversible process*. Thus, there are three attributes of a perfect random process: multiplicity, **unpredictability** and **irreversibility**."

"The random process distinguishes itself from the **deterministic process** during the first stage by the multiplicity of **simultaneously** possible outcomes. Each of these cases has a certain probability of turning up. The **probability** belongs to the *first stage* of the random process, before its realization; it is *virtual* because the second stage has not yet taken place; it is oriented towards an unpredictable future, and it is *transient* because it disappears as soon as the second stage takes place." (1989, p.14)

VENDRYES' concept is clearly related to **Bayesian subjective probabilities**.

From another viewpoint, R.V. JENSEN writes: "Attempts to reconcile the probabilistic laws of statistical mechanics give birth to a new branch of mathematics, called **ergodic** theory, which provides a means of classifying different **deterministic dynamical systems** with irregular **behavior**. In particular, this **classification** scheme defines symptoms for a **hierarchy** of different **classes** of random **behavior**, "statistical diseases" of increasing severity" (1987, p.176).

Ergodic systems allow for **randomness** within a general **determinism**. Further along, **chaotic systems** seem completely random, but still possess an underlying **determinism**. It becomes thus necessary to consider that pure **determinism** and pure **randomness** are only idealized abstract conditions.

These are reasons why collected statistics on the past of a random process do not allow a precise and secure prediction of any future **situation**.

2715

RANDOM RELATION^{1) - 2)}

"The relation between two systems who are independent from each other" (P. VENDRYES, 1973).

In VENDRYES words: "Relations between two systems are **deterministic** when they are connected and random when independent from each other" (1973, p.7). "Independent" here means that both systems are determined by causes which are not linked.

A similar random relation exists when a system suddenly receives unforeseen **inputs**: somebody travels to some place and, precisely there is killed by an earthquake.

A defined relation starts to establish itself when the **contact** is established and is thus in many cases largely unpredictable. This concept has produced recently in France the appearance of consultants who scout still ignored new technological developments which could later influence existing enterprises.

2716

RANDOM SEARCH PROCESS⁵⁾

A process of active probing of possible **configurations** within a **network**.

According to R.W. FULLER and P. PUTNAM such processes appear in **networks** when there is a **drive factor**. They tend to the formation of areas of relative **dominance**.

These authors state: "What stops a random search is reinforced again and again – everytime the associated **drive factor** is excited – because what satisfies a **drive factor** once will do so again if it catches the basic principle involved. Such **correlations** are **invariant** in the sense that if the random search is re-excited, the same stable **configuration** of nervous activity dominates" (1967, p.105).

This confirms independently HEBB's view on **habitation**.

This type of processes is probably at work in any kind of **networks**, nervous or other.

2717

RANDOM WALK²⁾

An exploration of some **concrete** or **abstract space** without any determining **guidance**.

S LEVY reminds us of the probability theorem that states that "Starting from any point in a random walk restricted to a **finite space**, we can reach any other point any number of times" (1992, p.303).

The condition for a random walk is that no **attractor** should exist within the **space** considered or, in other words, that no **gradient** be present.

Once some **reinforcement** factor appears within the explored **space**, the "explorers" search tends to become organized. This is basic for the appearance of **self-organization** in **networks**, for instance of **social robots**.

It is also the case for many *seemingly* aperiodic **oscillations**: markets **fluctuations** for example cannot be satisfactorily modeled by random walks, because while their **behavior** is **chaotic**, it is however *not* perfectly **undetermined**.

In human generated more or less **periodic processes** (for ex. stock markets evolution) a loosely **deterministic factor** is present and active. This factor is psychological in each participating individual, but at the same time psychosocial among the **group** of investors as a **whole**. Markets, for ex. are not only fluctuating in relation to economic indicators, but also according to investors and speculators moods and **beliefs**, as they are not purely rational **agents**, nor omniscient.. If the majority are optimistic, the prices rise; if they turn pessimistic, the prices fall.

Moreover the shifts present two other defining characteristics:

- they are **self-organizing processes**, with critical **thresholds of instability**
- as shown by ELLIOTT in the 1930's, **long term** movements can be graphically split into alternating medium and short component **waves** which appear to be grossly **self-similar**.

→ ELLIOTT's waves; Self-similarity in the WEIERSTRASS function

2718

RANDOM-CHOICE PROCESS ^{1) - 5)}

According to H.T. ODUM: "... speciation like other creative work involves a random-choice generating **process**, followed by a choosing system" (1971, p.159). ("choosing device" would be possibly a more suitable term).

ODUM explains: "New species are formed when new **adaptations** receive better **loop reinforcement** and **reward** from the system in which speciation is occurring". Here, the "system" is obviously the **ecosystem**, or **environment**.

ODUM adds: "... species are developed for the compatibility of systems. The systems view regards concurrent speciation as a coordinated **adaptation** to evolving **networks**... Speciation is best considered as the **process** of adapting **parts (populations)** to evolving systems. In human affairs the **evolution** of specialized industries with their specialized occupational **populations** is an equivalent **process**: each industry receives its selective **reinforcement** according to its economic reward for contribution to other **circuits**" (Ibid).

The choosing device tends thus to reinforce the **network's coherence** and, eventually to expand its scope.

An interesting parallelism can be traced with P. VENDRYES' concept of **autonomy** through probability **selection mechanisms**.

2719

RANDOMNESS ^{1) - 3)}

1) The non-**causal correlation** between successive **events**

2) The character of any collection of **objects** that cannot be simplified through any ordering device.

J. CASTI defines randomness as "maximally complex" (1994, p.9). This does not seem to be adequate, as **complexity** most generally evokes **order** in systems. It would be better to consider "random" as maximally *complicated*, i.e. **algorithmically incompressible**, as CASTI himself states (Ibid).

The 19th century French philosopher A. COURNOT defined it as "the crossing of independent causal series". Independent, that is, within the limits of our **knowledge**.

In effect, this generic term covers various different meanings, as shown by M. BODEN who distinguishes at least three: "**Absolute randomness** (A-randomness, for short) is the total absence of *any order or structure whatsoever* within the **domain** concerned, whether this be a class of **events** or a set of numbers (It is notoriously difficult to define A-randomness technically, but for our purposes this intuitive definition will do).

"**Explanatory**" randomness (E-randomness) is the total lack, in principle of *any explanation or cause*... If an **event** is A-random, it must be E-random too. (Since explanation is itself a kind of **order**, A-randomness implies E-randomness) It follows that it is often unnecessary to distinguish between them...

"**Relative**" randomness (R-randomness) is the lack of any **order** or **structure relevant to some specific consideration**. Poker-dice, for example, fall and tumble R-randomly with respect to both the **knowledge** and the wishes of the poker-players... In practice, R-randomness is always identified by reference to something people might have regarded as relevant" (1990, p.223).

In other words, randomness, like **determinism** seems to be an explicative categorization (not much explicative, at that). This appears clearly in the following comments.

J.von NEUMANN (as quoted by B. HAYES) wrote (in 1951!): "Anyone who considers arithmetical methods of production random digits is, of course, in a state of sin" (1993, p.114). von NEUMANN insisted that there are no such a thing as random numbers "per se" and that the production of a series of so-called random numbers through some "strict arithmetic procedure" was in fact equivalent to the use of an **algorithm**, which is of course entirely **deterministic**.

As shown by HAYES such **algorithms** may in fact generate series of "pseudo-random" num-

bers. However, after a sufficient number of runs, the **algorithm** will start to repeat the same numbers.

The objective reality of randomness in itself may even be debatable. J. BONITZER observes: "... in order to find a probability or a distribution of probability in a random series of **observations**, such a series must unavoidably have been constituted in some way or other (it is not simply given) - and by whom, if not by the *observer*, who must at least, consciously or not, decide to accept it? It cannot be helped, seemingly, that the **observer** pops up, precisely where he was supposedly be eliminated" (1988, p.49).

From this viewpoint, it is noteworthy that all random **games** (dice, roulette, etc...) are *constructed* and produce quite predictable probabilities, for the major profit of any games organizer.

No **phenomenon** is without causes - in plural. The complex mix of numerous concurrent causes at any moment in the **behavior** of **complex systems** generates *deterministic chaos*, which offers the general appearance of **random behavior**.

In D. BOHM and F.D. PEAT's words: "Randomness is thus understood as the result of the **action** of the very small **elements** on each other, according to definite **orders** or laws in an overall **context**" (1987, p.131).

→ **Complexity (Algorithmic); Random Number**

2720

RANDOMNESS (Constrained) ¹⁾

The limitation in randomness which results from the **scaling process**.

The **scaling process** defines more and more precise **limits** for the possible position of any **structural element** in a system (which may be for example the bronchioles in the lung, or a fine detail in the **representation** of the **WEIERSTRASS function**).

At any **level**, it is still impossible to exactly pinpoint the position of the **element**. In other words, randomness never disappears completely, but can be evermore reduced in **space** as well as in **time**.

This gives a firm base to the **concept of ergodic relation**.

From the viewpoint of the **WEIERSTRASS function**, the remaining randomness at any **level** corresponds to the impossibility to differentiate the function at any **time**.

It should however be noted that this randomness constrained by **scaling** excludes the case of giant **fluctuations** in **systems far away from equilibrium** (or possibly, such giant **fluctuations** do manifest the **emergence** of **scaling** at a higher level).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

2721

RANDOMNESS (Pseudo)²⁾

The character of a sequence of apparently random numbers created by using some specific **rules**.

Such a *constructed* randomness is of course not really random. As already observed by J.von NEUMANN, it is possible to generate an apparently perfectly random series of numbers in a completely **deterministic** way... which is exactly the contrary of randomness, even if it is possible to introduce an "asymptotic decrease toward 0 of the self-correlation function of the numbers in the series", as expressed by S. DINER (1992, p.350). As this implies a kind of "loss of **memory**" of the **initial conditions** (Ibid) the relation with **chaotic dynamics** is evident.

2722

RANDOMNESS REDUCTION¹⁾

According to R.W. FULLER and P. PUTNAM any **learning process** should be considered "... as a reduction in the randomness of sequences of **behavioral elements**" (1967, p.104)

This effect is obtained through a **random search process** which tends to the formation of more or less local **relative dominances**, i.e. by the establishment of stabilized **patterns**.

While these authors are mainly concerned with the **brain**, this model seems applicable to any **network** in its **organization process**.

2723

RANDOMNESS (Restricted)³⁾

Systemic randomness, i.e. randomness within a system is, by necessity, limited. A system totally submitted to randomness could have no internal **order** at all, and thus could not be a system.

Systemic **organization** is possible only by way of **constraints**, i.e. the existence of admissible (authorized) **connections** among **elements** or **subsystems**, combined with impossibility (or prohibition) of other **connections**.

Constraints tend to become differentiated in different areas of the system. In this way, degrees of **order** and randomness become locally distributed.

As the system as a **whole** can remain performant only as long as its specialized **processes** and **subsystems** function in a non-contradictory way, there is a paired restriction to randomness among **levels**:

1°- The **subsystems** and specific **functions** tend to become better interconnected and compatible.

2°- The system as a whole imposes to its **parts** its basic determined conditions of survival.

Randomness is also functionally limited: any system or **subsystem** has only a limited **repertory of responses** to specific **stimuli**, and even only some of these **responses** are the most probable ones.

ASHBY's experiment, with **homeostats** (1960, p.100-121) demonstrated, moreover, that even a **machine** specifically constructed to produce random **behavior**, tends towards at least statistical **stability**, provided it is constructed as a **net of subsets**, submitted to some **rules of interconnections**. Without these last ones, there can be no **coherence** whatsoever, while, of course, the **rules** introduce a measure of constraining general **determinism**.

The most typical random-restricted systems are the **ecosystems**, where, within the **limits** of global **determinism** imposed by geophysical **cycles**, numerous vegetal and animal interconnected **populations** fluctuate in ways practically unpredictable.

Respect to the **environment**, systems are "anti-random", using, as demonstrated by P. VENDRYES (1942) specific **reserves** to counteract perturbing variations imposed upon them. This **concept** is obviously related to ASHBY's **Law of Requisite Variety**.

2724

RANGE¹⁾

"The **set of states** onto which **transitions** are defined" (K. KRIPPENDORFF, 1986, p.63).

A problem with many **processes** in **concrete systems** is that their range is ill-defined or not defined at all, and difficult to establish. This complicates **decision-making**, and still more so when the range is not **stable**. A good present example is the hypothetical range of the greenhouse effect in global and regional climate.

2725

RATCHET¹⁾

A mechanism consisting of a pawl, or hinged catch that engages sloping teeth on a wheel, allowing for rotation in only one direction.

Such a mechanism introduces an intermittent stop and go **process**. It is generally related to a step function. It produces discontinuous **phase transitions**, passing through a succession of **critical states** which trigger sudden jumps after periods of apparent **stability** that can be quite long.

By analogy the ratchet can be seen as a device that secures **irreversibility** of intermittent processes and may lead to incrementally accumulative effects. In fact, it tends to block negative or counter active **feedbacks**.

In a sense it can be regarded as a kind of anti-regulator.

2726

RATE¹⁾

The **level** of production per unit of **time** in a **process**.

Rates can be constant or **variables**. When variable they can vary periodically or in an irregular way.

In his **Systems Dynamics**, J.W FORRESTER uses **flow** rates in a very specific way, to define the present, *instantaneous flows* between the various **levels** (i.e. operative **processes**) in the system. There is generally a **feedback** between the **levels** and the rates. The **flow** rates are determined by the **levels** in accordance with the **rules** defined by the **decision functions**. Conversely, the **flow** rates will determine the **levels**. The global results could possibly alter the global **decision-making**.

2727

RATIO SCALE²⁾

A way to represent **growth** graphically.

On such a scale equal vertical distances represent equal percentage **change** (fig. a and b from E. DEWEY and E. DAKIN, 1950, p. 242)

The simple arithmetic representation shows **growth** in absolute terms. The apparent accelerating growth hides the fact that relative growth is merely constant.

The ratio scale is also known as **semi-logarithmic scale**.

→ **Growth (Explosive or exponential); Optimum (Dynamic)**

2728

RATIONALITY ACCORDING TO DESCARTES³⁾

René DESCARTES stated in the following way the four precepts which are basic according to him for one to "conduct correctly his reasoning and seek *truth* in the sciences":

"... never to accept anything for true which I did not *clearly* know to be such;

"... to divide each of the difficulties under examination into as many **parts** as possible, and as might be necessary for its adequate solution.

"... To conduct my thoughts in such order that, by beginning with **objects** the simplest and easiest to know, I might ascend by little and little, and, as it were, step by step, to the **knowledge** of the more complex; *assigning in thought a certain order even to these objects which in their own nature do not stand in a relation of antecedence and sequence*.

"... in every case to make enumerations so complete, and reviews so general, that I might be assured that nothing was omitted." (1947, p.175-6) (Translation by Saxe COMMINS and Robert N. LINSKOTT, 1947).

This famous text certainly justifies some comments from a systemic viewpoint:

1. DESCARTES "seeks **truth**", but the hereafter quoted sentence seems to show that his **model** of "**truth**" is geometry's one, i.e. the **truth** of an abstract conceptual **construct**, or in other words, a **model** or, at most, an **algorithm**. The problem of **ontological truth** is not solved (neither is it by systemics, but at least, it is clearly stated: reality is "veiled" (B. d'ESPAGNAT, 1985)

Immediately after enouncing his four precepts, DESCARTES says: "The long chains of simple and easy reasonings by means of which geometers are accustomed to reach the conclusions of their most difficult demonstrations, had led me to imagine that all things, to the **knowledge** of which man is competent, are mutually connected in the same way, and that there is nothing so far removed from us as to be beyond our reach, or so hidden that we cannot discover it..." (p.176)

2. The word "clearly" (in DESCARTES text in French: "évidemment" = "evidently") and, of course, the whole of the first precept, places DESCARTES, just as any one of us, in the **observer's** position, that he does not examine. Moreover, DESCARTES was not able – as we ourselves are now – to distinguish "evidence" by direct **perception** and "evidence" technically constructed (as for example when physicists use a particles accelerator).

Finally, the notion of "evidence" becomes quite nebulous when it refers to the human affairs, unavoidably scrutinized by **observers**, quite different from each other psychologically and culturally. Inevitably, rationality becomes more or less subjective and tainted by **values**.

3. The second precept contains the seeds of the whole **reduccionist** research **method**, of extraordinary **efficiency** when applied to reducible **phenomena**, but which inconveniently eliminates the complex **interactions** between **elements** and **processes**.

4. The third precept tends to obviate this inconvenient, but the experience of three and half centuries shows that complex **interactions** generally cannot be again pieced together in such a way and thus remain ignored.

The last part of this precept shows that DESCARTES was conscious of the multicausality problem as well as the one about **simultaneity**. However, he does not say us how his "thought assignment" may lead to the discovery of this **order**, of which he reasonably presumes the existence.

5. The last precept cannot, unfortunately, guarantee us that we did not omit something. Moreover, while it seems to herald the statistical **method**, it does not contain anything related to the reduction of **variety** by way of statistics.

2729

RATIONALITY (Bounded)^{3) - 4)}

The limited degree of rationality in **decision-making** due to the limited computational abilities of the decision-maker.

This concept was established by H. SIMON (1969, p.214-29). As stated by J. CASTI: "SIMON assumed that economic agents can never make truly **optimal decisions** because they are inherently limited in the amount of **information** that they can process prior to having to make a **decision**. Accordingly, for SIMON, all **decisions**, economic or otherwise, generally lead to a nonoptimal "satisficing" kind of **behavior**" (1990, p.231).

As a consequence, SIMON finds it very important to reduce the extension of what must be computed: "... if an **organism** is confronted with the problem of behaving approximately rationally, or adaptively, in a particular **environment**, the kinds of **simplifications** that are suitable may depend not only of the characteristics – sensory, neural, and other – of the **organism**, but equally upon the **structure** of the **environment**" (1969, p.215).

It becomes thus of paramount importance to establish efficient **criteria** for structural **simplification** of **situations**, without losing their really significant characteristics. The nature of of an efficient structural **simplification process** appears clearly through SIMON's parable about **Hora and Tempus** watchmakers.

Most generally, the two opposite aspects to be taken care of, for **simplification** previous to **decision-making**, are the necessity of **maintenance conditions** of the system and the need for sufficient **degrees of freedom**.

2730

RATIONALIZATION (Spurious)²⁾³⁾

In many cases our acquired mental and in particular logical **frames of reference** are used to produce arguments that look rational, i.e. apparently deduced in a satisfactory way. However, our supposedly rational reasoning is frequently bended and distorted by implicit prejudices, or by **ideologies** of some kind, of which we may even be unaware.

Beliefs of any kind should be closely scrutinized in order to avoid fooling ourselves and risking to run into unadverted problems.

→ **Assumptional analysis; Awareness, Falsifiability; Observation (self-); Underconceptualization**

2731

REACTION DELAY²⁾

"The **span of time** needed for a **control** to register a **disturbance** and produce a **response**" (B. WALLISER, 1977, p.97).

The **response** not being instantaneous, the delays themselves can introduce **disturbances** into the **process** and complicate the **control**. This in turn may increase the cost due to an excessive use of the **control**. Fine tuning of any **control** must thus evaluate the effects of reaction delays and take them in account.

2732

REACTION of a system¹⁾

"A system **event** that is deterministically caused by another **event**" (R.L. ACKOFF, 1972).

The causal **event** is thus necessary, but also sufficient to produce the **change** of **state**. In such cases, the **behavior** of the system is strictly passive: it has no possibility to modify it, i.e. it is in a no **autonomous situation**.

2733

REACTION-DIFFUSION SYSTEM²⁾

A system dominated by opposed **sets** of forces, of which one tends to amplify differences and the other one to dampen them (After M. BUCHANAN, Inside Science Nr.121, p.3)

This type of reactions appear in systems in **process** of **dissipative structuration**, as for example the Belousov-Zhabotinskii reaction. They lead to the appearance of typical **patterns** of **growth**, as **hexagonal structures**, **TURING structures**, or **fractals**.

2734

READINESS (Conditional)¹⁾

This a conditional **potential** for **behavior**, more subtle than the behaviorist's conditioned **behavior**. D M. Mac KAY proposes this notion as follows: "Suppose... someone tells you "it's raining". You may be immersed in a book, and may not feel inclined even to grunt an acknowledgement. But this does not mean that your **understanding** of the **message** has had no effect on you. If a sudden call comes for you to go out of doors, you may now be ready to reach for umbrella or mac... What has been affected by your **understanding** of the **message** is not necessarily what you do – as some behaviourists have suggested – but rather what you would be **ready** to do *if* given (relevant) circumstances arose. It is quite possible that relevant circumstances may never arise, so that a naively behaviouristic approach would reveal no sign that you had understood the **message**. It is not your **behaviour**, but rather your **state** of **conditional readiness** for **behaviour**, which betokens the **meaning** (to you) of the **message** you heard" (1969, p.22).

2735

REAL WORLD PROBLEM

→ **Problem (Soft)**

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

2736

REALISM (Experiential)³⁾

Within the general frame of the new field of cognitive science, G. VOLLMER, quoted by H. TOTH thus explains the basic tenets of experiential realism:

"a) a commitment to the existence of the real world

b) a recognition that reality places **constraints** on concepts

c) a conception of **truth** that goes beyond internal **coherence**, and

d) a commitment to the existence of stable **knowledge** of the world.

...Experience here is taken in a broad rather than a narrow sense. It includes everything that goes to make up actual or potential experiences of either individual **organisms** or **communities** of **organisms** – not merely **perception**, motor movement, etc., but *especially* the internal genetically acquired makeup of the **organism** and the nature of its **interactions** in both its physical and social **environments**" (1983, p.XV – in TOTH, 1983, p.307).

These concepts are quite akin to PASK'S **conversation's theory** and von FOERSTER'S **cybernetics of 2nd order**.

→ **Realism, hypothetical and Ontological skepticism**

2737

REALISM (Hypothetical)³⁾

D.T. CAMPBELL stated in 1961: "My general orientation I shall call a hypothetical realism. An 'external' world is hypothesized in general, and specific entities and **processes** are hypothesized in particular, and the observable implications of these hypotheses (or hypostatizations or reifications) are sought out for verification. No part of the hypotheses has any 'justification' or **validity** prior to, or other than through, the testing of these implications" (1961, p.17).

However, CAMPBELL did not yet consider the deeper nature of 'verification' or 'justification' or '**validity**'.

It was more or less at the same time that G. PASK, H.von FOERSTER and others started to scrutinize the role of **observers** and of their acquired and constantly renovated **consensus** in the **knowledge** of reality.

G. VOLLMER, quoted by H. TOTH thus explains the main tenets of hypothetical realism (1992):

"All **knowledge** is hypothetical, i.e. conjectural, fallible, preliminary. There exists a real world, independent of our **consciousness**; it is structured, coherent and quasi-continuous: it is at least partially knowable and explainable by **perception**, experience and intersubjective science..." (p.28 – in TOTH, 1983, p.307).

Knowledge is thus based on **consensus**, but is somehow anchored in reality and verified or falsified by experience. However no result is ever absolute, as already explained by POPPER.

2738

REALISM (Structural)²⁾³⁾

This concept was introduced by H. POINCARÉ (1894-1912) (1902, p. 248-71). It sustains that the relations discovered through theories that have been systematically confirmed, do reflect "real" aspects of the physical world, as it is, independently from man" (L. SOLER, 2001, p. 82)

It is noteworthy that in her critical note, SOLER still puts "real" within quotation marks and uses the word "reflect"

In fact, there is a quite general **consensus** among epistemologists who examine the validity of scientific endeavor: our **knowledge** of the outside world is always relative to our human perceptive abilities and to our conceptual capacity for constructing models in our **nervous system**, and specially in the neo-cortex in our **brain**

2739

"REALITY" (Riddle of)³⁾

B. GAINES considered this riddle in a 1984 paper, in which he considered the problem of **modeling** "reality" (the unique way we have to learn something about it): "... the most outstanding characteristic of human kind is that we all are, and always will be, **modellers**" (1991, p.356).

Our problem is thus to try to evaluate our "Groping in the dark" (MEADOWS, D., et al – 1982).

GAINES finds and discuss three basic **modeling** attitudes (1977, p.358-65):

"- ZERO: There is no **method** of reality;...

"- ONE: There is one correct **method** of reality;...

"- MANY: There is an indefinite **variety** of **methods** of reality"

The first attitude corresponds to radical skepticism; the second one to any exclusive **modeling methodology**; and the third one, to a kind of positive experimental scepticism.

E. SCHWARZ writes: "We were led to the idea that "reality" cannot be reduced to the physical world, but that it has two equally "real" aspects: the usual physical world of **objects**, where **energy** is the pertinent **parameter**, and the logical world of **relations**, where **information** is the relevant **parameter**" (1992, p. 773).

In accordance with this view, what we call reality is a combination of **energy** and **information**. (itself merely modulated **energy**) for the human **observer**, able to construct such a **model**.

It could be added that "reality" has obviously different **meanings** in different cultures: see for example "La Pensée Sauvage" by Cl. LEVI-STRAUSS.

This matter is very much relevant for **systemics**, because is becomes a firm foundation for the concept of **models**, which merely aim at *representing* reality.

N. LUHMANN'S view, as interpreted by O. THYSEN (1995, p. 15) is that: "Reality" is only real in so far as it is observed reality, and no system has access to any "real reality". WITTGENSTEIN made the same point in a different way. A good example is the sight of stars at night. It is the human **observer** which creates a "celestial show" out of a complex set of luminous sensations resulting from light emissions from thousands of stars, completely **heterogeneous** in the **space-time dimension**.

In this example, it should be noted that:

1- the picture of "reality" is always slightly different for two or more observers

2- no reconstruction of "real reality" would ever be possible because it is absolutely fleeting as time is "running on"

→ **Ontological skepticism**

2740

REASON³⁾

"A manifestation of articulated belief, as reflected in the presence of tangible, visible, expression of that belief" (J. WARFIELD, 1989, p.11).

This is kind of an operational definition, to be used in **Interpretive Structural Modeling**, as proposed by WARFIELD. (The ultimate nature of reason is, of course, a very controversial subject, that cannot be discussed here).

WARFIELD adds, interestingly: "More generally, reason will be seen as high in quality when the form of its expression is not chosen intuitively in deference to **habit**, but is specifically tailored to satisfy recognized and articulated **communication** needs. Conversely it will be seen as low in quality when the form of its expression is colloquial and indifferent to the requirements of **description** and audience" (Ibid, p.12).

However, reducing the satisfactory manifestations of reason to its communicatory quality obviously is of course far from exhausting the subject.

2741

REBOUND EFFECT¹⁾⁴⁾

A positive **feedback** effect of some innovation on a specific **process**.

For example it frequently happens that a technical **progress** that helps to produce some commodity at a lesser **cost** and with a reduced use of **energy** or raw materials, induces a higher consumption of the product. This leads of course to an increase in uses of energy and

raw materials. A well known example in the 19th Century was the enormous increase of steel consumption after the invention of the BESSEMER process. During the 1980s and 90s, we have witnessed the replacement of big-frames computers by tens of millions of personal computers. Of course, as a result, the use of all kinds of **inputs** increases on a global **scale**. Accordingly, it is in no way certain that technical progress necessarily leads to a better global **sustainability** (See, for ex., the recent "Stuttgart Charta on Information Society and Sustainability" - Forum Info 2000 Bonn - July 2nd, 1998).

A sociology of the uses of **artifacts** would be a very needed complement to progresses in technologies in order to reach a better global **evaluation** of technologies weight in global human **ecology**.

Rebound effects have also been observed in demography: After great hecatombs through **pandemics** or war, the birth rate frequently surges and compensates the losses quite quickly. The same **effect** can be observed for instance in burnt down forests. Rebound effects are thus an obvious feature of **complex systems**.

In most cases, rebound effects come as a surprise to the **observers**.

2742

RECAPITULATION

→ **Complexity (Accumulative)**

2743

RECEPTOR ¹⁾

Natural organ or artificial device able to register certain **signals** and to transform them into a **code** acceptable to the system.

The term, originally a biological one, was used by A. LOTKA (1956, p.363-5), but never entered in widespread use. J.G. MILLER uses the term "**input transducer**", which he limits to the devices able to register **elements** of **information**.

According to A. LOTKA, the receptors are the initial **elements** of the devices he called "**depictors**", needed by systems to obtain a **representation** of their **environment**. The receptors transmit the results of their **perception** to the "**elaborators**" (p.363-65).

2744

RECIPROCITY ²⁾⁴⁾

"A mutual or cooperative **relationship**".

Reciprocity is, of course, possible only when the **relationship** is sufficiently repetitive.

Such a **situation** exists, for instance, in specifically connected **neurons** in **neural networks**, or in people interacting frequently with each others in **groups** of limited **size**.

It generally seems to be a pre-condition for the shaping of wider **cooperation** in **social systems**, human or other.

Reciprocity is of course a **feedback**, and can be positive as well as negative, in both senses of an acceleration or deceleration **process**, or its favorable or unfavorable results, in a psycho-sociological **meaning**. (See: A. RAPOPORT on Games theory, 1959)

→ **Tit for tat strategy**

2745

RECOGNITION ¹⁾²⁾⁴⁾

The adaptive and **continuous correlation** of **elements** in a give physical **domain** to the new **events** taking place in another physical domain more or less independent of the first one (G. EDELMAN, 2000, p.109)

EDELMAN adds: "These **adjustments** take place without any previous instruction, through **selection** within a hypervariable **set**.... These recognition systems are based on similar principles..."

- there is a **variety** (in french: "diversité") **generator** inside the internal domain
- there is an **interaction mode** between the external domain, and the various **repertoires** inside the internal domain
- there is a differential **amplification** of some **elements** of the internal domain" (Ibid)

This last principle is concurrent with RUMELHART & Mc CLELLAND'S **Parallel distributed processing**.

EDELMAN gives the following examples: "In immunology these two domains are obviously antibodies and antigenes. In **development** they are the genetic and the epigenetic (i.e.: cellular **environment**). In the neuro-sciences they are dynamic **neuronal structures** and **sets** of **informations**, or **stimuli** originating in the external world" (Ibid)

MATURANA would probably accept "stimuli", but reject "information": the world is as it is and there is no information without a **brain**.

For EDELMAN, the brain is a **network**. In the quoted interview (as in his former works) he develops his **model**.

Cooperative or associative behavior cannot work if the elements cannot somehow "recognize" each other.

This is specially true in complex **relationships** in **groups**.

The deepest nature of so-called "recognition" is however quite enigmatic.

While it would be highly anthropomorphic to say that atoms of hydrogen "recognize" atoms of oxygen, or chlorine as possible "associates", it is however obvious that chemical valencies that imply potencial **complementarity** have in a very basic sense a social **meaning**.

Characteristic significance by associative capacity through some forms of **compatibility** and complementarity does also emerge all along biological **levels**, for ex. from enzymes on.

2746

RECOGNITION BY INFERENCE ^{3) - 5)}

The capability to recognize **patterns**, figures, objects or people is a property of **neural networks**.

Fr. CRICK and Ch. KOCH give the following example and explain it: "If you look at a person whose back is turned to you, you can see the back of the head, but not the face. Nevertheless your brain infers that the person has a face. We can deduce as much because, if that person turned around and had no face, you would be very surprised.

"The viewer-centered **representation** that corresponds to the visible back of the head is what your are vividly aware of. What your **brain** infers about the front would come from some kind of three dimensional **representation**" (1992, p.112).

Of course, such three-dimensional **representation** is present in our cerebral **network** as a very basic feature, acquired during the infancy. It seems moreover that there is more to it than this: We also should be very surprised if that person would have a cat's or dog's face, which implies that we have a somehow permanent category of "human beings" in our neural **network**.

Moreover, the nature of our internal and potential **representations** obviously depend of our **cultural training**. We easily recognize the **symbols** of our culture (say: the Cross, the Crescent, the Mandala, our flag, etc...), but do not recognize at all or easily **symbols** of other cultures.

2747

RECOMBINATION ¹⁾²⁾⁵⁾

A process of generation of new **elements** or new **rules** in an **adaptive system**.

The system may be a biological species, a genome, an artificial life unit, or a **pattern recognition** device, or even conjecturally a **set** of **memes**..

In J. HOLLAND's terms recombination "implements" a "pervasive **heuristics**" (1992, p.197)

In nearly all cases, recombination may affect in a positive way the adaptive character of the **goal-seeking system**, because "it provides a powerful **mechanism** for discovering and exploiting useful **schemata**" (Ibid. p. 191).

However, in some cases, it may have negative **effects**, as in the **conjugation** of two similar recessive pathogenic alleles.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

2748

RECONSTRUCTABILITY ANALYSIS²⁾

"A set of computer aided methodological tools for dealing with the **relationship** between **wholes** and **parts**, i.e. between overall systems and their various **subsystems**" (G. KLIR, 1991, p.141).

KLIR, who created and developed this **methodology**, states: "At the highest level of generality, reconstructability analysis may be said to be concerned with two complementary problems:

1. The reconstruction problem: To what extent is a given system **description** inductively inferable from **descriptions** of **subsystems** deductively inferable from it? (1958, p.6).

(George KLIR, states this point in the following terms: "The aim of the reconstruction problem... is to determine the smallest possible **subsystems** by which a given overall system can be adequately represented) (1990, p.33).

2. The identification problem: To what extent do the **descriptions** of a given collection of systems determine (deductively) the **description** of a single system of which they are each **subsystems**".

"While recognizing what is now commonplace in science, i.e. that "the **whole** is *greater* than the sum of its **parts**" i.e. that it is (usually) not possible to infer from detailed **knowledge** of **subsystems** similarly detailed **knowledge** of a system of which they are **parts**, practitioners of R.A. seek **decompositions** of systems into **subsystems** such that as great a **simplification** as possible is achieved while keeping the loss of **information** regarding the original system within acceptable **limits**". Hence the characterization by CONANT (1988) of R.A. as "a form of enlightened **reductionism**" (1958, p.6).

Says KLIR: "In general the term "system" is used in R.A. for a **set** of **variables** together with some characterization of the **constraints** among these **variables**. Each **variable** of a system is viewed as an **abstraction** of some real-world **attribute**. It is associated with a finite **set** of **states** (**values**) each of which represents a class of appearances of the corresponding **attribute**" (1990, p.34).

These **values** or "**states**" must be measured.

KLIR adds: "In all these measures, the amount of **information** is measured in terms of the amount of reduced **uncertainty**. The more our total ignorance (full **uncertainty**) regarding **states** of relevant **variables** is reduced by the given system, the more **information** the system contains."

"... A discovery that a system can be represented by a specific **set** of **subsystems** may provide the investigator with some **knowledge** that is not available, at least explicitly, in the corresponding overall system. For example, the **subsystem configurations** may give him in-

formation about causal **relationships**, the significance of the individual **variables**, the strength of dependencies among them, etc..." (p.35).

One could add that the **whole** is not only greater than the sum of its **parts**, but is *something else*, in some sense, more than the **parts** and in another sense less than their sum.

The totality masks many specific characters of the **parts**, some of whom may –or may not – be significant for the **whole**. One may surmise that the significant ones are those which intervenes in the **interrelations** among the **parts**.

However, up to some point, these **interrelations** remain occult when we look only at the global integrated system.

Thus, discovering them seems to be the mainpoint of R.A. Moreover they can be discovered only through their **action**, which can be measured through the varying **states** of the **subsystems** or **parts**, interconnected in specific and exclusive ways.

2749

RECONSTRUCTABILITY ANALYSIS (Basic simplification Principle in)²⁾

"A sound **simplification** of a system should minimize the loss of relevant **information** with respect to the required **reduction** of its **complexity**" (1986, p.270).

G. KLIR explains: "As in the **identification** problem, the loss of **information** is measured here by the increase in **uncertainty**. An appropriate measure of **uncertainty** is thus used again as an arbiter. Among all comparable simplifications of the given system, we accept only these with minimum **uncertainty**. For **probabilistic systems**, for example, the simplification principle becomes the well established "principle of **minimum entropy**" (p.270).

2750

RECONSTRUCTABILITY ANALYSIS (Consistency in)²⁾

A. RAMER and L. LANDER state: "Two systems are called consistent if they induce identical marginal **distributions** of the **set** of **variables** they share. In other words, the **variables** common to both systems are given the same **distribution** by either parent system. An arbitrary family of systems is consistent if its members are pairwise consistent. This condition is often called a hypothesis of local **consistency**, as opposed to a stronger requirement called global **consistency**. Global **consistency** mandates the existence of a hypothetical overall system whose **subsystems** include our family of systems" (1990, p.448).

2751

RECONSTRUCTABILITY ANALYSIS (Identification Problem in)²⁾

G. KLIR writes: "... (this problem) is concerned with a given **structure system** where **elements** are viewed as **subsystems** of an unknown crucial system. The aim is to make meaningful **inferences** about the overall system from **information** in the **subsystems** and, possibly, some additional background **information**"...

"The identification problem belongs to the general **class** of problems of reasoning under incomplete **information**. This type of reasoning is fundamentally different from deductive reasoning in the sense that conclusions are not entailed in the given premises: it is often referred as "**ampliative reasoning**" (1986, p.268).

"In general ampliative **inferences** are not precise. In the identification problem, one can determine only a **class** of overall systems that are implied by the **information** in the given **subsystems**" (ibid.).

2752

RECONSTRUCTABILITY ANALYSIS (Inconsistencies in)²⁾

G. KLIR states: "Two kinds of inconsistency in **structure** are distinguished in R.A.: Local and global inconsistencies. Local inconsistency pertains only to **variables** that are shared by two or more **elements** of the given **structure system**. Any two **elements** that share some **variables** are *locally inconsistent* if their characterizations of the shared **variables** are not exactly the same. A **structure system** is *globally inconsistent* if all **parts** of its **elements** are locally consistent and, yet, the reconstruction family is empty.

"Local inconsistencies are usually caused by the fact that the individual **elements** of a **structure system** are not perfect **models** of **reality**. They are developed from or validated by different **data sets**, each of which is incomplete, imprecise, or otherwise imperfect in some specific sense peculiar to it. Hence, local inconsistencies are a result of our ignorance regarding the **subsystems** involved and, consequently, it is meaningful to try to resolve them by a suitable **method**. At this time, however, research in this area is still in its infancy.

"Local as well as global inconsistencies can also be treated by rejecting the **information** that creates them." (1986, p.269)

2753

RECONSTRUCTABILITY ANALYSIS (Problems in)²⁾

A. RAMER and L. LANDER describe the following problems, met in reconstructability analysis:

"Approximation problem

If the reconstructed system is different from the original one (and... this is almost invariably the case), how close can we come to that original system?

"Complexity problem"

Exhaustive search through the spaces of possible reconstructions exhibit hyper-exponential **complexity** and therefore are numerically intractable. There is therefore a need for **heuristics** that may guide the search and thus limit its **complexity**. The questions dealing with existence, characterization and applicability of **methods** that may obviate the necessity of a complete search can be described as the **complexity issue**

"Consistency problem (Local)"

Structure systems encountered in practice often exhibit a lack of **consistency** in that the marginal **distributions**, derived from the various **parts** of the system, do not quite agree. This inconsistency is called local, and we would often like to consider it as a minor one. Can it somehow be tolerated and can we still arrive at a reasonable reconstruction?

"Consistency problem (Global)"

Given an arbitrary, locally consistent family of systems, can we determine whether they admit a reconstruction and are thus globally consistent?

"Labeling problem"

Can a family of simple variables be selected to form a system of distinct representatives for the **elements** of a given **structure system**? Here we have actually two distinct problems. One is the very question of existence of such a system of representatives, and the other concerns the usefulness and **meaning** of such a selection... In reconstructability theory we view them as the labeling systems for the general **structure**

"Proximity problem"

What numerical measures are suitable for determining the proximity of two reconstructions? Is any one such measure superior to another? Can such measures be considered metrics or **norms** on appropriate space of reconstruction?

"Reconstruction family problem"

The determination of all admissible overall systems which agree with a given structure system

"Recovery problem"

Given a **structure system**, which originated from an overall system, how can that system be rebuilt, or even an overall system that would agree with our **structure system**?

"Solution problem"

Given only a consistent family of systems (thus a **structure system**), how can we identify, among all the candidate reconstructions, the optimal one?" (1990, p.449-50)

This all sounds quite esoteric. A case example could be very useful.

2754

RECONSTRUCTABILITY ANALYSIS (Procedures in)²⁾

According to R.E. CAVALLLO and G.J. KLIR, three kinds of procedures should be used in Reconstructability Analysis:

"1) Procedures for generating, in an orderly fashion, all desirable **structure** hypotheses;

"2) Procedures for **evaluation** and comparing the general **structure** hypotheses;

"3) Procedures through which it can be decided, at every stage of the reconstructability analysis, which of the generated and evaluated **structure** hypotheses should be used as a basis for further analysis" (1979, p.163).

2755

RECONSTRUCTABILITY ANALYSIS (Systems Concepts in)²⁾

G. KLIR proposes the following definitions for use in Reconstructability Analysis:

"- **Subsystem**: a system based on a **subset** of **variables** of another system.

"- **Structure system**: a collection of systems considered as a unity.

"- **Overall system**: a system that consist of all **variables** in a **structure system**.

"Individual systems of a **structure system**, which are often called its **elements**, may share some **variables**. **Elements** of a **structure system** are coupled through the shared **variables** and, consequently, interact with each other. By definition, each **element** of a **structure system** is obviously a **subsystem** of the corresponding overall system" (1986, p.268).

2756

RECONSTRUCTION FAMILY²⁾

"A class of overall systems that are implied by the **information** in the given **subsystem**" (1986, p.268).

Klir states: "The **size** of the **class**... reflects the inadequacy of the **subsystem representation** of the overall system. The true overall system is always a member of the reconstruction family, but the **subsystem information** is not sufficient (except for special cases) to identify it uniquely. Hence, **inferences** one can make about the overall system from given **subsystems** are inherently imprecise.

"The determination of the reconstruction family is basically a matter of formulating and solving appropriate algebraic equations. These equations characterize, *within the mathematical formalism employed*, the **rules** of projecting the unknown overall system (e.g. overall **state**, or **state** probability) to the corresponding entities of the given **subsystems**. In addition, the *equations are always constrained by the requirements of the mathematical apparatus employed*" (p.269).

In other words, no formalism is neutral, nor is the decision to use it.

KLIR adds: "When the reconstruction family constrains only one system, the identification of the overall system is perfect. In these cases, which are rather rare, the ampliative reasoning becomes deductive reasoning. It may also happen, of course, that the reconstruction family is empty. This means that the given **structure system** is inconsistent" (p.269).

2757

RECONSTRUCTION PRINCIPLE^{2) - 3)}

Reconstructability analysis can be used to produce correct overall **states** that are not contained in the **data** (Adapted from G. KLIR, 1990, p.60).

KLIR comments: "It is important to realize that the reconstruction principle is methodologically different from the usual conception of **inductive** reasoning. The latter is almost exclusively conceived in terms of the so called "straight **rule**", which is well expressed by the following precept offered by RESCHER (1980, p.100):

"When a certain percentage of **population P** have in fact be observed to have a particular trait **T**, then adapt *this very value* as your answer to the question "What proportion of the entire **population P** have the trait **T**?"

"The reconstruction principle violates the straight **rule** since it modifies, in general, the **frequencies** of **states** obtained from given **data** and may produce additional **states** that are not contained in the **data** at all".

"How to explain the reconstruction principle? First, let us recall that the principle is based on the identification of **subsets** of **variables** of the overall system that are strongly related. These **subsets** of **variables** are expressed by the superior reconstruction **method**" (KLIR, 1990, p.75).

RESCHER's concept of **induction** must be based essentially in statistical or experimental **inquiry** used as **reductor** of **variety**.

On the contrary, R.A. introduces "superior hypotheses" and is open to wide exploration of the preselected **data** related to specific **parts** or **subsystems**.

2758

RECONSTRUCTION PROBLEM²⁾

G. KLIR states: "This problem is concerned with the question of how a given **generative system**, assumed to be employed in **modeling** some aspect of reality, can be broken down into appropriate **subsystems**. A collection of **subsystems**, which in our terminology is a **structure system**, is appropriate when it is sufficient for reconstructing the original overall system to an acceptable degree of approximation".

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

"Two preference orderings are essential for comparing competing **structure systems** in the reconstruction problem. One is expressed in terms of the amount of **information** that is lost when the overall system is replaced by a **structure system**. Let this preference be called *information ordering*...

"The second preference ordering involved in the reconstruction problem is connected with the size of **subsystems** contained in the **structure system**: smaller **subsystems** are preferred. This latter preference ordering may be called a **complexity** ordering since a reduction in the size of a system tends to reduce the size of its **description**. It is only a partial ordering" (1991, p.106-7).

As to the practical aspect, KLIR states: "Both the reconstruction and identification problem are computationally very hard. As a consequence, the applicability of reconstructability analysis has been limited to systems with a modest number of **variables**, say a dozen or less. Recent developments of some powerful **heuristic** procedures by Roger CONANT seem to indicate, however, that systems with hundreds and possibly, even thousands of **variables** could be analyzed on existing large computers" (p.348).

2759

RECRUITMENT^{1) - 4)}

The addition of new **elements** or replacement of lost ones in a system by **elements** obtained from another one.

Recruitment takes place either when a system has been severely reduced by some **disturbance** (an ecosystem after a hurricane f. ex.), or when it is growing (a country accepting immigrants). The new **elements** need be compatible with the system, while not necessarily similar to any former or still existing ones, in order to avoid **rejection** or subsequent internal **disorder**.

In **ecosystems** according to S. REICE: "Recruitment has a major impact on the outcome of **competition** and, consequently, on **community structure**. This idea, dubbed supply-side **ecology** by R. LEWIN, asserts that physical transport **processes** are important determinants of **community structure** because they set the supply of colonists to habitat **patch-work**" (1994, p.432).

Recruitment is at least in part a **random process**, as the **identity** of the new **elements** is never perfectly defined. It may as well deeply modify the **identity** of the recruiting system. S. REICE states: "Stochastic (**random**) recruitment in a **heterogeneously** disturbed, patchy **environment** results in high overall species **diversity**" (p.427).

2760

RECURRENCE THEOREM²⁾

A **dynamic system** will go back arbitrarily close to its initial **state**.

This theorem was introduced by H. POINCARÉ and is, in fact, historically the first theorem related to **ergodic systems**. It is to be noted that POINCARÉ's theorem says nothing about the **time span** needed to observe the return to the initial **state**: in very **complex** (and **chaotic**) **systems**, it can become so long as to lead to a practical impossibility.

2761

RECURSION¹⁾

A **mechanism** of circular **self-reproduction** of **components** and/or **relationships** in a system.

Or: The cyclical creation or recreation of **elements** or **interrelations** in a system through the application to existing **elements** or **interrelations** of a specified **feedback** or **set of feedbacks**.

The **feedbacks** are specified within the system from its very **autogenesis** on, through **organizational closure**, of which recursion is practically the signature.

An example is **fractal branching**.

Recursion can in principle be applied on its own results without **limits**.

F. FRISCHKNECHT and J.P.van GIGCH observe: "Recursion is a finite prescription of an infinite **process**" (1989, p.243), and: "**Nonlinear feedback** (i.e. recursion) is the novelty that burst into physics challenging its old axiomatic **models**. Recursion replaced mathematical axiomatization by **constructivism**, **state** by **process**, **models** by **metamodels**" (p.249). The same authors state the very important conclusion that these **metamodels** "... only furnish second-order **knowledge**, they do not predict, they just simulate. This is the only way to understand **complexity**: to know its **rules**, the **states** being unpredictable" (Ibid).

"Unpredictable" should be possibly better replaced by "only imprecisely predictable", as **chaotic randomness** is still basically **deterministic**.

Recursion is an essential feature of the **autopoiesis theory**. **Organizational closure**, i.e. the permanent self-reconstruction by a system is entirely dependent on recursion. This is seemingly also true in the psychology of identity, in psycho-pathology and in social and cultural systems.

Recursion seems to operate only within **networks** (which necessarily possess **rules** of **self-organization** and **self-reproduction**).

A formal calculus of recursive **self-reference** has been developed by G. SPENCER BROWN (1969) and extended by F. VARELA (1975).

2762

RECURSION (Level of)^{1) - 4)}

"A level at which a **viable system** is in operation, as an **autonomous part** of a **higher-level viable system**, and containing within itself **parts** which are themselves **autonomous viable systems**" (St. BEER, 1974, p.72).

This definition is applicable to all **viable complex systems**, including **social systems**. However, as BEER himself discovered and explained, the problem of modern governments (of any type), is that none has a satisfactory **model** of the real workings of the society it is supposed to "govern", i.e. regulate. This shows ignorance of the basic principle according to which: "No regulator can actually work unless it contains a **model** of whatever is to be regulated" (p.34).

The situation seems to be still worse than this: Governments and politicians apply recursion to their own **beliefs**, or imaginary **model** of the society to be governed. (See "**governability**"): Recursion on figments generates... metafigments.

In a more abstract sense, recursion produces basically "vertical" or **hierarchic structures**, that can be characterized by the prefix "**meta**", as in **metasystem** (van GIGCH), **metacontrol** (van GIGCH), **metalanguage**, **metamodel** (van GIGCH).

It is helpful in order to distinguish **logical types** or **levels**, avoid **paradoxes** and avoid confusion in **organizations**.

J.van GIGCH observes: "Levels of recursion do not necessarily carry implications concerning authority or **ethics**, i.e. higher levels of **control** do not have *more* authority or are *better* in the moral sense than lower ones" (1986 b, p.90).

2763

RECURSION (in mathematics)²⁾⁵⁾

The definition of a **function** in terms of itself.

2764

RECURSIVE EQUATION²⁾

An iterative equation in which the results of each step of calculation are reintroduced in the following step.

In many cases, such an equation is computer processed and the seventeenth decimal in the successive results is neglected. While the iterative **process** is **deterministic**, the neglect of successive seventeenth decimals leads to a progressively growing **unpredictability** and introduces **chaos**.

2765

RECURSIVITY or "recursiveness"^{1) - 2)}

"The application of a **function** to its own value to generate a series of similar values" (JOHANSEN BERTOGLIO - 1985).

Recursivity is a constructive **process**, not merely a structural **embedment** feature, as would be for example a set of wood carved Russian dolls.

The mathematical concept has been transferred into the **autopoiesis theory** and experimentally explored by M. EIGEN et al (1975, 1979 and 1992).

A. ZELENIKAR comments on recursivity in the following way: "**Processes** in an **autopoietic** system are organized circularly, as they depend recursively on each other; they form a recursive **closure**. Production **processes** are synthesizing, transforming or destroying various **components** which appear in an **autopoietic system**. For instance, destruction of **components** produces substrate on which **processes** of production can act. A unity assembles its **components**" (1988, p.208).

According to F. BAILLY, F. GAILL and R. MUS-SERI: "Recursivity corresponds to a principle of **information** economy by the use of one and only one reiterated formal law for each stage of **development**. Such a simplicity is perfectly compatible with a very rich combinatory and morphological power and its intrinsic uniqueness harmonizes well with the **representation** of an integrated and determined individuality" (1991, p.58).

Recursivity is also a **crosslevel process**, in which case it may be **self-similar** in a **fractal** sense. **Reproduction** of the **elements** (or **sub-systems**) and their characteristic **interrelations** is a **global process**, which operates, for example:

- in a living being, by the multiple action of its genetic **code**;
- in a society, by way of a **set of values**, norms and **knowledge**, transmitted through **processes** of education and instruction.

Recursivity makes the system's **behavior** *more or less* predictable, because it implies a limited (while sometimes gigantic) **repertoire** of possible **states**, given in sequences acceptable for the system.

Moreover, from **level to level**, some measure of **self-similarity** can be observed. **Organizational closure** is a **crosslevel isomorphy**.

In reference to human systems, J. JOHAN-NESEN makes an interesting comment: "At every **level** of recursivity, there will be two conflicting tendencies:

1. The tendency to function as **part** of the larger system
2. The tendency to maintain individual **autonomy**" (1991, p.44-5).

Thus, recursivity seems to be a result of a peculiar class of individual response to **interactions** (Those which are – or seem – useful to the **components**) and of a **constraint** favoring systemic **cyclical** or **catalytic self-reproductive processes**, through a kind of reciprocal conditioning. This could well emerge as a basic law of **sociogenesis**.

As observed by J.C. LUGAN, "The idea of recursivity breaks off from the **cause-effect linear concept**... It introduces a self-constitutive, self-producing and self-organizing **cycle**" (1993, p.92).

A similar opinion is G. BATESON's who considered **cybernetics** as "dealing with problems of **control**, recursiveness and **information**" (1979, p.227)

2766

RECYCLING ¹⁾

"Converting ... **wastes** into new products by using the **resources** contained in them" (adapted from the UNESCO – UNEP glossary of environmental education terms).

Nature recycles automatically all of its productions, even if this **process** sometimes covers eons. This is not the case for many human products which artificial character does not allow for their insertion in natural **cycles**, or because **accumulation** of **waste** is too fast to be accommodated by natural **processes**.

Recycling is a typical systemic theme. It covers practically all the products of human activity, and not only "solid" **wastes** as stated by the UNESCO – UNEP glossary.

Indeed, every product terminally becomes **waste** in the long run. And gases, liquid effluents and most of all, heat resulting from **entropy** production should be considered.

The systemic problem is to put the use of natural **resources** and **energy** as much as possible in a recurrent **circuit**. This aim implies scientific and technical research, economic rethinking and a change in socio-cultural **values** and subsequent management politics.

→ **Economics in systemic terms; World engine**

2767

RED QUEEN EVOLUTIVE PARABLE ^{1) – 3)}

L. CARROLL 's Red Queen parable in "Alice in Wonderland" alludes to the need to run evermore swiftly in order to be able to stay in the same place.

This strange **metaphor** now becomes a parable about competing **co-evolution** of species (or **organizations**). A favorable **adaptation** in one – for example, a predator – may bring negative results to the other, the prey. This orients the **evolutionary adaptation** of the latter in such a way to counteract the negative **effect**. After much "running", both species find themselves in the same relation.

D. HILLIS has now modeled this **process** on his **connection machine**, showing that this is a general **model** for countervailing evolutionary **processes**.

2768

REDUCIBILITY ²⁾³⁾

The many-times hypothetical presumption that a complex problem can be reduced to a host of solvable more simple ones.

See however "**Compressibility**"; "**Variety reduction**"

2769

REDUCIBILITY (Non-) ¹⁾²⁾

Non-reducibility is a typical property of **autopoietic systems**, which, by definition, must be **recursive**.

This means that the system cannot be much simplified, by suppressing **elements** and/or not considering recurrent reconstructive **interactions**, mostly multiple and **simultaneous**. Doing this could decisively alter it, or even destroy it.

→ **Eigen-; Eigen-value; Reducibility**

2770

REDUCTION (Emergence and)

→ **Emergence and Reduction**

2771

REDUCTIONISM ^{1) – 3)}

1. "A descriptive and investigative **strategy** which gives account of **phenomena** in terms of a series of isolated **parts**, coupled together by direct causal **linkages**" (T.F.H. ALLEN & T.B. STARR, 1, p.276).

2a. A principle "according (to which) all scientific concepts are reducible to a **set** of ultimately irreducible concepts" (R.L. ACKOFF, 1974, p.53).

2b. "The belief that everything in the world and every experience of it can be reduced, decomposed, or dissembled to ultimately simple **elements**, indivisible **parts**" (R.L. ACKOFF, 1991, p.325).

3. The claim "that properties of a **whole** are explicable in terms of properties of the constituent **elements**" (G. KLIR, 1991, p.24).

4. "... the task to find the simplest, most economical and (usually) most elegant **explanation** that will cover the known **data**" (G. BATESON, 1979, p.230).

T.F.H. ALLEN and T.B. STARR add: "**Ambiguity** in **relationship** between **parts** is met with further subdivision until the **ambiguity** disappears" (ibid).

As a result "Reductionism is thus the strongest possible way of ordering the list of the various sciences" (I.I. MITROFF and H.A. LINSTONE, 1993, p.165).

Commenting his definition, ACKOFF states that these "ultimate concepts", according to some "were provided by direct **observation**" and to others "thought of as undefined con-

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

cepts of a formal system". And, "Whatever their source, these concepts were identified as "physical thing predicates"; that is, physical properties of things".

BATESON adds to his definition the following caveat: "Beyond this, reductionism becomes a vice if it is accompanied by an overly strong insistence that the simplest **explanation** is the only **explanation**. The **data** may have to be understood within some larger **gestalt**" (Ibid).

For a good example, see: **Selection (Multi-level)**

Reductionism is a **paradigm**. R. ROSEN expresses this as follows: "The belief that any natural system can be so decomposed (note: i.e. extensively, and possibly limitlessly), and that the laws governing the motions of these particles can be determined, is the essence of reductionism" (1979, p.174). The "belief" is something like the hardening of an **assumption**.

The conceptual origins of reductionism are to be found in DESCARTES and NEWTON, if we are not going back in time to DEMOCRITUS, EPICURUS and LUCRETIUS.

The basic (and largely unconscious) tenets of reductionism seem to be the following:

- what should be researched are the properties of **objects**, which are "real" and perfectly knowledgeable
- the **observer** or experimenter is "transparent", i.e., without influence on the perceived **objects**
- the "**et ceteris paribus**" postulate can be applied without restrictions, which allows for **linear causal** explanations
- supposedly, no significant aspects of **phenomena** are thus left out, (forgetting for example **interrelations** between **elements** or **parts**, or between **levels**)
- larger **contexts** do not influence upon **phenomena**

Systems concepts are however not *opposed* to the reductionist approach, as they admit **levels of description**. This point was made as follows by P. WEISS (quoted by G. KLIR, 1991, p.26), who describes a neutral stand: "The reductionist likes to move from the **top down**, gaining precision of **information** about fragments as he descends, but losing **information content** about the larger orders he leaves behind: The other proceeds in the opposite direction, from below, trying to retrieve the lost **information content** by **reconstruction**, but recognizes that that **information** is not forthcoming unless he already had it on record in the first place. The difference between the two **processes**, (is) determined partly by personal predilection, but largely also by historical tradition".

This does not make clear that the main concern of the systemist are the **interactions** within the same **level** as well as between different **levels of complexity**, in the **whole**.

Moreover, as stated by I. PRIGOGINE (quoted by F. David PEAT, 1987, p.64), "... there is no "fundamental **level**" in nature but rather each **level** involves its unique **description** and is conditioned by the **levels** around it".

In some sense, reductionism is thus "inscribed" within the systemic approach as: "Nature... requires pluralistic **descriptions** and ... this pluralism must contain both **causal** and **synchronistic** aspects" (Ibid).

In an overview of this subject, J.A. GOGUEN and F.J. VARELA conclude: "Reductionism implies attention to a lower **level**, while **holism** implies attention to a higher **level**. They are intertwined in any satisfactory **description**; and each entails some loss relative to our cognitive preferences, as well as some gain" (1979, p.42).

Reductionism may also be understood as the use of OCKAM's razor, as stated by P. CHECKLAND, who writes: "And we use reductionism in another sense in explanation, explaining the results using the smallest number possible number of concepts, only importing more elaborate concepts when defeated in this" (1976, p.128).

Still another meaning frequently given to reductionism is the stand according to which social and biological sciences can ultimately be reduced to explanations based on physical sciences. While anything social or biological is by necessity based on physical properties, the reductionist stand ignores the existence of successive **levels of complexity** grounded on the **emergence of dissipative structures and synergies**.

On this topic D. CAMPBELL accepts: "... the limited **emergentist** principle that laws of biology, psychology and sociology exist which are not described by the laws of physics and inorganic chemistry. These **emergent** laws are compatible with the laws of physics and chemistry but not derivable from them" (1975, p.1104).

At long last, the fundamental difficulty becomes obvious: so-called laws must be non-contradictory between them to be acceptable on all **levels**. The best example has been the elimination of the vitalist stand in biology when the apparent impossibility of life in terms of classical **thermodynamics** was taken care of successively by such **models** as **open system**, **homeostasis** and finally **dissipative structuration**. It should be noted that none of these **models** are "laws", nor their applications limited to any particular scientific discipline.

P.M. ALLEN et al. observe that "the very success of reductionist science has... provided man with the power to radically change his **environment**. However, this science has afforded almost no **knowledge** of the probable **effects** of such **actions** in the **complex systems** en-

countered in the domains of biology, ecology and socio-economics. **Policy** today must be formulated in a world of ever increasing **interaction and complexity**" (1984, p.2).

2772

REDUCTIONISM AND CAUSALITY^{1) - 3)}

In his critique of the second and the third precept of DESCARTES "**Discourse on the method**", J.L. LE MOIGNE states: "Reductionism implies somehow **causality** and conversely" (1990a, p.19).

While DESCARTES suggested in his third precept to start "with **objects** the simplest and easiest to know" and "ascend by little and little, and, as it were, step by step, to the **knowledge** of the more complex" (1947, p.175), he did not explain *how to do this*.

He did not seem to be aware that the application of his second precept *destroys* these composed **objects** because their breakdown in simple **objects**, as he recommends, eliminates their numerous internal relations, keeping only some privileged one.

Moreover, it becomes less and less obvious, for example in physics with the case of the quarks, that "smaller" is also "simpler and easiest to know".

2773

REDUNDANCY¹⁾

1. Repetition of **elements** in a **message** or system which permits to circumvent **transmission errors** or functional failures.

2. A measure of how much **knowledge** about **parts** of the system allows to know something about other **parts**, due to known **constraints** between them (H. ATLAN, 1989)

3. "...the number and **variety** of internal **subsystems** which can perform the same **function** equally well" (W.D. GROSSMANN & K.E.F. WATT, 1992, p.10).

In relation to the first definition, it should be noted, in M. MARUYAMA's words that: "If a **message** can be **compressed** shorter by an efficient **coding**, then the amount of space saved by the **compression** is called redundancy" (1992, p.196).

This is the original **meaning** given to the term by C. SHANNON in his theory of **communication**. Redundancy here is used to compensate **noise** and to maintain **reliability** in the **communication process**. K. KRIPPENDORFF states: "English writing is estimated to be 50% redundant which account for the ability of native speakers to detect and correct typing errors" (1986, p.64). Redundancy is also useful for reconstruction of mutilated **messages**.

As to W.D. GROSSMANN and K.E.F. WATT they state: "Redundancy... provides **reserves**" (ibid., p.8). In this case, failure of one **circuit** or **channel** can be compensated and reliable systems constructed from somewhat unreliable **parts** (von Neumann).

If redundancy, in ATLAN's opinion, reflects **constraints**, or the **organization** of the system, it is however obvious that an excessively redundant system (i.e. very **constrained** one) cannot have much functional **meaning** and, if totally redundant, none at all.

This is why "one finds also **variety** or **diversity** as a property typical of the existence of an **organization**, especially when **complex adaptive behavior** is exhibited. This property is in fact opposed to the first one (i.e. redundancy) and it is a measure of the **uncertainty** or unexpectedness of the so-called **information content** of a system, in the formalism of **information theory**. As such it can be used to measure the **complexity** of a natural **organization**" (1989).

Thus, any **complex system** needs simultaneously **variety** and redundancy, which are in some sense complementary.

When the system ages, its redundancy diminishes, while its **variety** grows, up to a limit which is a characteristic of the system. The construction of **variety** uses up redundancy.

2774

REDUNDANCY in NETWORKS ²⁾

The existence of a multiplicity of **nodes** and **paths** between them, able to perform in an equivalent manner.

The theory of redundancy in networks was developed by W.S. McCULLOCH, W.H. PITTS and J.von NEUMANN, who showed that redundancy offered the only hope to obtain satisfactory operative results from networks made of sometimes unreliable **components**.

In St. BEER words: "...von NEUMANN propounded a mathematical theorem which showed that if one is prepared to go on increasing the redundancy of a network without **limit**, it is possible to obtain an **output** of arbitrarily high accuracy from a network whose **components** are of arbitrarily low **reliability**" (1968, p.201).

This is so in natural networks, like the cerebral cortex, which remains more or less reliable as a **whole**, even when numerous neurons have been lost, for example because of a cerebral haemorrhage. It is also the case in artificial networks and even in social ones, as may be seen when they repair themselves, sometimes after massive destruction of **elements** and **interconnections**.

2775

REDUNDANCY (Knowledge implicit in) ³⁾

O.S. AKHMANOVA states: "The redundancy of a text is a consequence of the fact that the different **elements** – words, and also **parts** of words, letters are not independent from each other. There are probabilistic **connections** between these **elements**, determined by the probabilistic **structure** of the **language**. It is just the **knowledge** (possibly unconscious) of this **structure** that allows us to fill in the abbreviations of the text" (1960, p.199).

"Probabilistic" should be understood as "defining more or less probable **connections**, in accordance with the specific **constraints** that characterizes the **language** used".

Such **constraints** per se are precisely "anti-probabilistic" and our **knowledge** of them is what allows us a significant "reading" of any text, even *more or less* pruned of its redundancies, by guessing "what should come now".

Of course, redundancy exists only when there is a **meta-knowledge**. Who does not know Japanese cannot perceive any redundancy in a **message** in Japanese, even if it is perfectly present therein.

2776

REDUNDANCY of POTENTIAL COMMAND ¹⁾

St. BEER states: "This subtle feature of effective **organization** was (thus)... named by the distinguished American cybernetician Warren McCULLOCH" (1968, p.457).

BEER explains it in the following way: "... it is the possession of **information**, rather than bestowed authority, that confers the right to act. So in any **network** of **channels** and **nodes**, some **sub-system** of the total system acquires a commanding state of **knowledge** at a given epoch of **time**... In a completely established **hierarchy**, it is known in advance what **sub-systems** work as **entities**, and which of them command what aspects of **control**. But in a **self-organizing** system, or in a system designed for **learning**, **adaptation** and **evolution**, it is necessary for alternative groupings to be possible. So the third form of **redundancy** lies in the potential for **command**: it is a **behavioral**, not a **structural component** of the system" (ibid).

The potential for **command** is, in last resort, the potential for creating new relevant organizing or regulating **interrelations**.

BEER emphasizes that: "The trick was learnt from the **brain**, once and again, and may readily be observed in operation in any social group" (ibid).

This is the most general explanation of the sudden appearance of organizing centers or new leaders in developing systems. It will probably also be the final basic condition of self-organizing **artificial intelligent** systems.

2777

REDUNDANCY (Spreading of) ¹⁾

G. BATESON states that redundancy is not only something perceived and helpful to the receiver of a **message**.

"In a wider universe, i.e., that defined by the point of view of the **observer**, this no longer appears as a '**transmission**' of **information** but rather as a spreading of redundancy... The activities of A (the **sender**) and B (the **receiver**) have combined to make the **universe** of the **observer** more predictable, more ordered and more redundant" (1973, p. 383).

There is however again a condition: The **observer** must know A and B's codes.

2778

REFERENCE CONDITION ¹⁾

The reference conditions of a system is a synthesis based on sets of reference **signals** relative to different aspects of the system's **behavior**.

W.T. POWERS who introduces this notion gives the example of a driver in a car, who is concerned **simultaneously** with **signals** related to the present state of the vehicle; to the state of the road, to the position of other moving objects; to the conditions of the weather, etc...

And all this is observational, i.e. depending on the physiological empowerment of the driver, that includes correct **perceptions**, synthetic capacity of the **brain** and good **performance** of the nervous and muscular **subsystems**.

(Adapted from the author's page on the web)

→ **Reference frame**

2779

REFERENCE ENTITY

→ **Stigmergy**

2780

REFERENCE (External) ²⁾

N. LUHMANN writes: "The difference between **subject** and **object** (thinking and being, **knowledge** and object) is nothing else but the distinction between self-reference and external reference" (1995, p. 8)

The autopoietic system connects itself with some external reference through **structural coupling**, i.e. "external" becomes "reference" only when the system reacts to some feature in its **environment** and, in some way, internalizes the "external".

2781

REFERENCE FRAME ³⁾

The coordinated **set** of **relations** between **elements**, usable for the comprehensive **representation** of more numerous or extended **elements** of **knowledge**.

The progressive construction of reference frames is a significant part of any **learning process**, be it in natural or in **artificial intelligent systems** (see "**connection machine**").

The Spanish neurologist J.M.R. DELGADO observes that: "Skills are not unveiled, because they do not preexist. Their neural mechanisms, including the frames of reference, must be constructed within the **brain**. Motor coordination and skillful performance do not emerge from the **brain**, but must be absorbed by it through the experiences and **information** provided by sensory **inputs**" (1993, p.302).

Reference frames are a result of specific **constraints** which result, and later on, lead to **rewards** considered positive and to the construction of interpretation **codes**, i.e. more **constraints**. However, once established, reference frames become **autopoietic**, by some **self-replication process**, not yet very clearly understood.

Writings, **semantic** and grammatical **rules**, scientific theories, religious **symbols**, and **ideologies** are reference frames (irrespective to our **evaluation** of the same).

They are kinds of open **algorithms**: they do not allow to discover some interpretation for something that they do not contain at least in an implicit form, but they permit nevertheless an enormous combinatory wealth.

They build up by **constraints** on the initial potential **variety** of the system (See "**order from noise**") and act as global **transducers**.

G. PASK states: "Although the reference frame depends upon the **observer**, his choice is conditioned by all his previous experience and by convention" (1961a, p. 121).

As noted by PASK, in science, the consensual selection of reference frames allows for comparable **measurements** and communicability of results (Ibid).

From the systemic viewpoint: "The reference frame itself is a system. It satisfies a definition proposed by Colin CHERRY that a system is an 'ensemble of **attributes**'" (Ibid., p.23).

→ **Frame**

2782

REFERENCE FRAME: Time – Space – Form ^{1) – 3)}

According to J.L.LE MOIGNE: "The modeling power of the **process** concept is a result of the surprising simplicity of the **transformations** types: when an **object** (or a family of **objects**) is processed and identified, its processing will always be framed without **ambiguity** inside of a permanent **triadic reference frame**. To act or interfere upon a given **object** is to affect its position in **time** (always), in **space**, frequently (by transportation or **transmission**), and/or its **form** or **morphology** (**transformation**) Doing, acting intervening, functioning,

changing or whatever, is in every case affecting the position of at least one **object** in a reference frame T.S.F.: i.e. Time, Space, Form" (1990a).

It seems useful to add that such a reference frame can exist only thanks to some form of **energy** which generates **transformations** of all types. One is indeed carried back to the basic group of irreducible concepts used within this dictionary: **Energy, Time, Space and Matter**.

Should one admit that information is a modulation of **energy**, nothing can seemingly escape from the T.S.F. **reference frame** or some equivalent one. Moreover, any **object** or system can thus be identified at any instant without any **ambiguity** or possible superposition within the **reference frame**.

2783

REFERENCE FRAMES (Evolving) ¹⁾⁴⁾

Reference frames-whether individual or socially more or less shared- are basically adaptive mental and behavioral devices, corresponding to specific **situations**.

However, **fitness** is not forever, precisely because situations do change. Any reference frame needs thus more or less frequent updating: it must be not only adapted, but also adaptive.

As observed for example by Th. KUHN in the case of scientific **paradigms**, such **changes** can be slow, difficult and even painful (in cases, they imply even impossible mental and/or behavioral shifts for some people)

This necessity for change can lead either to dramatic **discontinuities** (mental troubles, revolutions), or to more or less peaceful **transitions** through psychological change in **autopoietic** ways or shifting **consensus** among people through **conversation**.

The present transition toward the "**man-planet**" **system** through so-called **globalization** would be possible without tragedies only through a deep evolutive reconstruction of individual and shared reference frames worldwide, even if this is obviously a tall order.

→ **Adaptability (or Adaptiveness); Consensus; Conversation; Framing; Learning (Systemic); Purpose in social systems; Social cybernetics; System (Self-modifying)**

2784

REFERENCE FRAMES (Shared) ¹⁾⁴⁾

Every individual constructs his/her personal reference frame and none is perfectly identical to any other.

However they may be more or less similar and they need to be for any social life to become possible.

In fact, people engaged in similar **activities** (engineers for instance) share a technical reference frame in their specific activity, even if each engineer is working in his own slightly different way. Engineers are thus able to understand each other in their field, and also to develop similar habits and a specific **behavior** in their society.

In a wider sense, members of the same **culture** identify themselves through shared **beliefs** and common **understandings**: religious, linguistic, philosophical and behavioral.

While reference frames as extended to **communities** are a convenient **abstraction**, they correspond anyhow to common mental and psychical orientations, whose effects may lead to a **group coordination** and even "bring people in line" in the sense of the German word "Gleichschaltung"

→ **Cohesion; Consensus; Conversation; Groupthink; Social system (Human); Sociality; Socialization**

2785

REFERENCE STRUCTURE

→ **Stigmergy**

2786

REFERENCE VALUE ²⁾

The set-point or **standard** to which a **regulator** compares the observed values.

By comparing the observed values with the standard, the **regulator** produces an error's measure that is used to define a correction to be imposed by the **effector**.

In accordance with a **memory** (i.e. register) of previous **states**, several reference values may be inscribed within the system.

2787

REFLECTIVE CONVERSATION

→ **Stigmergy**

2788

REFLECTIVE SYSTEMIC PROPERTIES ⁴⁾

"Properties of a socio-cultural or political **system**, as observed on a visible **level**, that reflect **concepts** or **values** rooted in a deeper **level**" (Fuschl Conversations, May 2000 on "Social awareness")

The basic general organized **level** in such a system is the one of **values** and **norms**, explicit or implicit, generally of religious origin. If the explicit **organization** and **behavior** contradict the implicit **values**, the system's **stability** (and in cases, its survival) is at risk.

2789

REFLEX (Conditioned) ⁵⁾

"A reflex **response** which is developed in special **training procedures**" (J. ECCLES, 1977, p. 235)

As well known, the basic research in this subject has been done by I. PAVLOV.

Of course, when the reflex is conditioned, it is still conditional, i.e. the trigger **signal** is always needed and must be given in a precisely recognizable way.

When the reflex is not solicited during a long **period**, it tends to wane, but may generally more or less easily revived.

→ **Habituation; Hebb's rule stimulus**

2790

REFLEX (Functional) ^{4) - 5)}

A reflex is functional if it responds adequately to the **command** triggered by the **stimulus**.

A **behavior** is functional if it is adequately adaptive. The **functional behavior** however, is created at the reflexological (or instrumental) **level** through the ordered inclusion of a number of coordinated reflexes within a reflexological system:

- able to produce a considerable **choice** of different sequences
- integrated, i.e. working as a regulated unit.

ASHBY expresses it in the following way: "the value of one **part's behavior** cannot be judged until the **behavior** of the other **parts** is known; and the values of *their behaviors* cannot be known until the first **part's behavior** is known. All the valuations are thus *conditional*, each depending on the others" (1960, p.7).

2791

REFLEXIBILITY ²⁾³⁾

Norma ROMM connects reflexivity to interdisciplinary practice, in which both **agents** are at the same time participant and **observer** (1998, p.67, as quoted from BAWDEN by Romm)

She also tackles the difference between **interdisciplinarity** and **multidisciplinarity**, which "often amounts to a dialogue of the deaf in which incompatible research approaches are pursued in parallel with little or no **communication** between them : (as quoted from M. JONES in his paper "It all depends what you mean by discipline")

In fact in multidisciplinary meetings, **reflexibility** becomes generally drowned in a confuse and overbearing **noise**.

In a note in her paper N. Romm makes some observations about **transdisciplinarity**, but disclaims any intention to develop this aspect.

This is lamentable because it would seem that **transdisciplinarity** emerges as a set of practices by disciplinary specialists acting among them in a constant reflexive way that leads them to create multi-**cross-** (i.e. trans-) disciplinary **concepts** and **models**.

S.L. PAYNE reworked the subject in a subsequent article, but the differences between interdisciplinarity and transdisciplinarity remain still unstated (1999, p. 173-181). This is quite obvious in the general literature.

→ **Cross disciplinarity; Living systems; Taxonomies of systems**

2792

REFLEXION FROM REFLECTION ³⁾

To have two different spellings for what is considered the same word in many dictionaries comes now to be quite useful. The works of G. PASK, H. MATURANA, F. VARELA and D. SCHÖN, as well as in another style the work of P.P. GRASSÉ have illuminated the **difference** (as well as the **connection**)

Reflection has a psychological **meaning** related to its physical meaning. It takes two, or more, conversants "reflecting" to each other their views, to start a "**conversation**" in which each one is trying to interpret whatever the other is showing or saying him.

This kind of psychological **experience** "with the other" is also the basis of a human **structural coupling** in the way of MATURANA. It leads to a kind of cooperative **autopoiesis** through which each participant comes to accommodate the thus obtained experience through **perception**, into his own self-**understanding**. This is of course "reflexion" and a **recursive process**.

2793

REFLEXIVITY ¹⁾

The potentiality for any **component** of a **complex system** to exert some determinating **action** on any other **component**.

This concept has been introduced by J.W. SUTHERLAND in his "General Systems philosophy for the social and behavioral sciences" (1973, p.39, 99).

SUTHERLAND expresses that reflexivity can be "... so intense that the **part** removed from **context** for analysis becomes a fiction of no ontological (i.e., real) significance" (p.39).

Another important consequence of reflexivity is that, as any **component** may at any moment interact with any other one, the **macro-determinism** of the system is somewhat reduced, and **semi-deterministic chaos** may appear.

2794

REFRAMING ²⁾³⁾

A shift in one's **viewpoint** that allows for different aspects of an **issue** or **theory** to be taken in account.

Reframing has been a characteristic mental and conceptual attitude in **epistemology** and even in specific scientific disciplines all along the 20th century.

It is highly visible in scientists and thinkers as different as MARX, PLANCK, EINSTEIN, BERTALANFFY, BACHELARD, KORZYBSKI, etc., and more recently D. BOHM and M. FOUCAULT and of course H.von FOERSTER and MATURANA and VARELA.

Reframing has also been extensively used by the Merida School of **Interpretive Systemology** in Venezuela for the study of social issues in that country.

Such a mind stretching **strategy** by which the very **methodology** of **inquiry** is expanded in order to avoid multiple contradictions leaves lingering doubts about the nature of human **understanding**, at least as it was firmly and strongly believed to be in classical thinking until at least the end of the 19th century.

→ **Knowledge; Ontological skepticism; Order (Implicate); Reference frame**

2795

REGENERATION ¹⁾

The condition of a **complex system** which recycles or reproduces its different **elements** through an **array** of interconnected and interacting closed **loops**.

M EIGEN and P. SCHUSTER explained this process by developing their **hypercycle concept** (1979).

While regeneration is never perfect, this **periodic recycling process** insures the **dynamic stability** of the system, as long as a certain critical **level** of copying errors is not exceeded.

Ageing and **senescence** seem to be related to the crossing of such a **threshold** by progressive **accumulation** through **time**.

While the regeneration **mechanism** is internal, it is still dependent, as observed by H.T. ODUM, on "... a regenerative complementary **ecosystem**" (1971, p.287) (or **suprasystem**).

2796

REGENERATION CIRCUIT ^{4) - 5)}

J.O. WISDOM in a paper on "The hypothesis of **cybernetics**" debates the concept of "regeneration circuit", derived from the reverberating **circuits**, which, according to certain neurologists (A. FORBES, R. LORENTE de NO), do exist in the **brain** and could be the carriers of **memory**. (1956, p.117-8). Such **circuits** must necessarily be repetitive, or even permanent, in order to allow for their use each time that they are needed. This has been thus expressed by W.S. MC CULLOCH: "... A train of impulses in a regenerative loop preserves the **form** of the fact without reference to the particular moment when it was experienced" (Ibid., p.118).

It must thus be necessarily an intermittent and more or less cyclical or scandened process (hence the term "scansion" proposed by WISDOM).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

It would be interesting to investigate the re-generation **circuits** at the **level** of societies and cultures memories.

2797

REGENERATION CYCLE²⁾

The succession of **states** through which a system returns to its optimal **state** after some **perturbation**.

This concept is basically an ecological one.

It could however be extended to any system and is closely related to the **autopoietic** and **organizational closure model**.

Regeneration cycles are specific to dynamic **equilibrium systems**. It is however somewhat doubtful if any system at all is able to regenerate itself *perfectly*.

→ **Climax**

2798

REGIME¹⁾

A type of more or less regular **behavior** characteristic of a system.

St. KAUFFMAN distinguishes three basic types of regimes: **ordered**, **complex**, or **chaotic**. He states: "In the ordered regime, many **elements** freeze in fixed **states** of **activity**. These **frozen elements** form a large connected **cluster**, or **frozen component**, which spans, or *percolates*, across the system and leaves behind isolated islands of unfrozen **elements** whose **activities** fluctuate in complex ways. In the **chaotic** regime, there is no frozen **component**... In this chaotic regime, small **changes** in **initial conditions** unleash **avalanches** of **changes** which propagate to many other unfrozen **elements**. These **avalanches** demonstrate that, in the **chaotic** regime, the **dynamics** are very sensitive to **initial conditions**. The **transition** from the ordered regime to the **chaotic** regime constitutes a **phase transition**, which occurs as a **variety** of **parameters** are changed" (1993, p.174).

2799

REGIME DYNAMICS²⁾

As systems are **oscillators**, they tend to some sort of periodic regularity, i.e. to a dynamic regime. A dynamically stable regime correspond to a **toric** or periodic **attractor**.

However, a regime is not necessarily stable in the long run. Some very unfrequent environmental **disturbances** may unsettle **stability**, throwing the system "out of gear", either into another dynamically stable regime – possibly at a higher **level** of **complexity** if the **disturbance** is a permanently heightened **flow** of **energy**, or into **chaotic behavior**.

Any given regime is in many cases taken for granted. Such a mental rut is quite dangerous, because it leads to a false sense of security and eventually to dramatic awakenings.

2800

REGION¹⁾

An area in the **field** of a **state-determined system** in which the **lines of behavior** from all points remain located (after ASHBY, 1960, p.48).

According to ASHBY such a region is stable. From his comments and developments, it appears that "region" is practically a synonym of "**basin**" in **topology**.

He explains, for example that: "If a **line of behavior** is re-entrant to itself, the system undergoes a recurrent **cycle**. If the **cycle** is wholly contained in a given region, and the **lines of behavior** lead *into* the **cycle**, the **cycle** is **stable**" (p.49).

The region **model** corresponds more or less to the **field** concept. It has a practical value in any **situation** where a **group** or **population** (or whatever kind) is wandering in an **environment** with **resources** variable in **space** and in **time**.

→ **Foraging theory; Parasitism; Symbiosis; Value Theorem (Marginal)**

2801

REGRESSION (Organizational)^{1) - 4)}

The return to a former and lesser **level** of **organization**.

This notion has been introduced by E. SCHWARZ (1992, p. 771-2) who applies it mainly to **human systems**.

He writes: "We should mention the **distinction** between the dynamic coherent **differentiation** of the **morphogenetic** phase..., and the chaotic fragmentation of **structures** that often occurs in the alea sector around the **bifurcation**, in system fragilized by a tropic **drift** incompatible with their **components** and/or their **environment**. The destructure of the ex-USSR giving way to pre-communist countries, and the destructure of the Federation of Russia giving way to ethnic states, is an impressive example of a multiple turn organizational regression" (Ibid).

Tribal wars in Africa after the demise of global colonial political **structures** are another example.

This **process** reflects the implicit persistence of **parts** at lesser **levels** of **organization** within great **complex systems**.

2802

REGULATION^{1) - 2)}

1. "Any systematic (**rule-like** or determinate) **behavior** of one part of a system that tends to restrict the **fluctuations** in **behavior** of another **part** of that system" (K. KRIPPENDORFF, 1986, p.64).

Regulations translate **constraints** through appropriate devices, i.e. **regulators**. They are one of the most general and fundamental feature of systems in their dynamic dimension and appear in practically every aspect of natural or constructed ones.

KRIPPENDORFF states: "While both **parts** must lie in the same **feedback loop**, regulation involves this basic **asymmetry**: the **regulator** detects and responds to discrepancies from some expectation (**criterion, goal**) which is of an ordinality higher than the **behavior** so assessed and it computes the **actions** appropriate to keep the **behavior** to be regulated within desirable **limits**" (Ibid).

Regulation and **control** are merely *near* synonyms. Regulation seems more general, as many natural regulations (in **ecosystems**, in **living systems**, and even in **social systems**) are automatic. **Control** implies generally the introduction by a human **decider**.

2. **Stabilization** of the completed **structures**" (1977, p.152).

J.L.L.E MOIGNE interprets regulation as a special case of a more general phenomenon, "**equilibration**", which includes as well the **stabilization** of the not yet completed **structures**, "themselves in **morphogenetic evolution** within the **fields** of forces of the modeled **object**" (Ibid).

LE MOIGNE insists (opportunistly, it seems) on the difference between regulation and **control**. The latter involves most generally the notion of strictly pre-programed ordering of the **process**, in the way it was introduced by the original **mecanicist cybernetics** and implies a considerable rigidity.

LE MOIGNE coincides with K. BERRIEN's view according to which regulation needs no **memory** to be adaptive (1968). It seems however obvious, that a **regulator** needs at least some permanent trace of the past of the system, be it under the guise of a predefined optimum **state** or a list of acceptable **states**, or be it a register of acceptable minima or maxima. Such traces are easily overlooked, specially in natural **regulators**.

A wide-embracing survey of the subject (in French) can be found in A. LICHNEROWICZ et al (1977).

2803

REGULATION (Developmental)⁵⁾

"The sequential **activation** of a series of regulatory **switches** that in turn activate **networks** of other genes" (D. ERWIN et al., 1997, p.133).

This is a very general biological **mechanism** at the genetic **level**. The authors state: "Many different **classes** of regulatory genes share a common DNA sequence known as the **homeobox**, which predates the origin of animals" and ... "In complex **organisms** the **hox cluster** specifies the **development** fate of individual

regions within the body, and usually the genes are activated and expressed in the body in the same order as their **position** in the **cluster**" (Ibid).

Note: "Hox" is shorthand for "homeobox"

→ **Morpho-space; Timekeeper**

2804

REGULATION (Emergent)²⁾

A regulation at a higher **level** of **complexity** resulting of the **coalescence** of **damping** devices.

G. NICOLIS and I. PRIGOGINE have shown "that the **evolution** of a **fluctuation** depends on the **competition** between **growth** and **damping** through **diffusion** or, more generally, through **surface effects**" (1977, p.462).

If a **runaway fluctuation** gets totally out of **control**, it will destroy the system. While this sometimes happens, **damping** through new types of limitative **interactions** generally appears. It tends to become a permanent **effect**, through repetitive **sequences** and thus becomes a new **regulation** at a higher **level**.

This **process** is clearly the root of higher **level regulation** in societies in formation **process** (animal or human). It is related, for example, to pheromones in anthills or beehives, and to **values** and legal devices in human societies.

2805

REGULATION (Ergodic)²⁾

A regulation that, with **time**, becomes independent from the initial **state** of the system.

J. EUGENE writes: "Only a system that counts with at least one **feedback** coupling is able to develop itself in an ergodic way" (1981, p.65).

The ergodic regulation corresponds to an "**ergodicity domain** within which the very young system may not be able to resist small **disturbances**. When becoming mature, the system acquires a resistance to strong **disturbances**, until, finally it loses any resistance to any kind of disturbance" (Ibid).

J. EUGENE adds the noteworthy following comment: "Such ergodic **processes** correspond to von BERTALANFFY's **equifinality**. Their interpretation led formerly to metaphysical finalism, specially in relation to **phenomena** of biological **regeneration**, as described by Hans DRIESCH (1909). This author sets that the **organism's** development is conducted by a force, which he calls "**entelechy**". (The concept of **ergodicity**) shows that finalistic and metaphysical concepts are not needed to explain the development of systems. Such development, of a dialectical nature, results of the disequilibrium of a system in which the values of the **inputs** (Xt) and the **outputs** (Yt) are in a permanent contradictory movement, the **outputs** modifying the **inputs**, which in turn modify again the **outputs**" (p.67).

The theory of ergodic regulation has been developed by and W. Ross ASHBY (1956) and O. LANGE (1965).

2806

REGULATION (Polycentric)^{1) - 2) - 4)}

The existence of various **regulators** at different **levels** and places in a **complex system**.

A completely centralized regulation in a quite **complex system** faces the problem of **time lags**: in many cases the central **regulator** acts upon conditions that have already changed and becomes inefficient, if not downright harmful. Moreover, when long **communication lines** are needed, **noise** may distort the **information** (both **bottom up** and **top down**) and induce inadequate **responses**.

While a global **regulator** is still needed in order to maintain the general **coherence** in the system, regulation may at least be partially decentralized. Local and specific **regulators** may be set up, in conformity with the **heterogeneous** character of the system. This leads to a degree of **heterarchy**, giving **autonomy** to functional **subsystems**.

This type of organization exists in physiology. It could be generalized in **human systems**, and even probably in complex artificial systems.

2807

REGULATION (Self)^{1) - 2) - 4)}

Regulation that arises from the nature of the constituent **parts** of the system and their interplay.

Self-regulation is related to the **complementarity** and the satisfactory **integration** of **parts** or **subsystems** in the system.

It implies the **co-variance** of the systems **functions** and, normally, the existence of **hierarchical control** and of a central **control subsystem**.

The capacity of self-regulation endows the system with a degree of **autonomy**, within the specific and differentiated **limits** it embraces.

In human systems as enterprises, **organizations**, cultures, etc...any modification of **functions** or **subsystems** or relations with the **environment** should be carefully studied and planned, in order to avoid deep **perturbations** or even destruction of the self-regulation ability.

2808

REGULATION (Self) in Societies⁴⁾⁵⁾

Sociologists and theoretical economists of the past described self-regulation in societies under various guises long time before its cybernetic **modelling**.

F. CAPRA gives the following examples: "The best known, perhaps, are the "invisible hand" regulating the market in the economic theory of A. SMITH, the "checks and balances" of the US Constitution, and the interplay of thesis and an-

tithesis in the dialectic of HEGEL and MARX. The **phenomenons** described by these **models** and **metaphors** all imply **circular patterns** of **causality** that can be represented by **feedback loops**" (1977, p. 62)

However, as also stated by CAPRA "...but none of these authors made the fact explicit" (Ibid)

As a result these **models** (with the exception of the "checks and balances" of the US Constitution) became all more or less ideologically tainted in their applications, with at times, very dubious results.

Accordingly, in human systems as enterprises, **organizations**, economic and in political law making, any modification of **processes**, **functions**, **subsystems** or **relationships** with the **environment** (previously clearly described) should be carefully scrutinized. Any subsequent **planning** should watch for **underconceptualization**, in order to avoid what is generally known as "vicious circles".

These are in fact uncompensated and unilateral **positive** or **negative feedbacks** unwittingly introduced.

This is also the case with so-called "self fulfilling prophecies".

→ **Design**

2809

REGULATOR^{1) - 2)}

Any device whose use is "to keep the **output variables** of the system constant in spite of **disturbances**, which are represented by the **input variables**" (G. KLIR, 1991, p.155).

Any **input** can indeed be viewed as a **disturbance**, even if necessary for the system: ingested food, for example, must be appropriately **metabolized** under **control** of physiological regulators.

Regulators are generally **error-controlled**. In the words of ASHBY: "In this case the regulator's **channel** for **information** about the **disturbance** has to pass through a **variable** (the "error") which is kept as constant as possible (at zero) by the regulator R itself. Because of this route for the **information**, the more successful the regulator, the less will be the **range** of the **error**... To go to the extreme: if the regulator is totally successful, the **error** will be zero unvaryingly, and the regulator will be cut off totally from the **information** (about D's value) that alone can make it successful - which is absurd. The error-controlled regulator is thus functionally incapable of being 100 percent efficient" (1958, p.93)

(D is for **disturbance**) (See hereafter: "Regulator Paradox")

However, as stated by R.C. CONANT and W.R. ASHBY: "Error-controlled regulation is in fact a primitive and demonstrably inferior method of regulation... The regulations used by the higher

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

organisms evolve progressively to types more effective in using **information** about the causes (at D) as the source and determiner of their regulatory actions" (1981, p. 190)

This is related to **anticipatory behavior**, **early warnings** (as **disturbances** are announced if and when their forerunning causes are perceived or registered), and **feedforward**.

2810

REGULATOR PARADOX (The)³⁾

Regulators need necessarily be able to perceive *errors*. Out of this condition, a paradox does arise, stated in the following terms by B. PORTER: "If the regulator were totally successful, the **error** would exhibit *no variety*, the regulator would accordingly receive no **information** about the external **disturbances** acting upon the plant, and successful regulation would thus be impossible" (1976, p.228)

This could however imply a logical fallacy, as **disturbances** could obviously produce a **variety** of **errors**, and thus *waken* the regulator.

2811

REGULATORS (Short history of)¹⁾

Practical and effective regulators anticipated for long time the **cybernetic** theory of **regulation**. Some examples can be found in various antique cultures and even in archaic ones. Some old Chinese and Medieval artefacts also included regulators.

R. VALLÉE makes the point: "The classical example of regulators, the best known of them being WATT's regulator (1785 – first theory due to MAXWELL around 1870) is a good illustration of **negative feedback**. Nevertheless it is not the most ancient: middle ages and antiquity give other examples such as the mill corn-dispenser, or clepsydra water supply" (1993a, p.85).

2812

REIFICATION^{1) – 3)}

The fallacy to treat or regard an **abstraction** or a **model** as a **concrete system**.

This "fallacy of misplaced concreteness", in WHITEHEAD'S words is one of the most serious risks that a systemist can incur in. It has two different aspects:

1) The danger to construct a pure and unqualified **abstraction** and to use it or work on it as if it were part of the real world. Examples could be: "Homo economicus"; "the State", "Development", etc., and even possibly "Intelligence quotient".

2) The danger to use a constructed **model** of some **concrete system** as if the system were a faithful (i.e. **isomorphic**) *copy* of the **model**.

Such attitudes are ruinous for the credibility of **systemics**.

2813

REINFORCEMENT¹⁾

The strengthening of some characteristic in a system by repetition of a **stimulus-response** effect.

Reinforcement cannot occur against unfavorable **selection** pressure. It generally starts as a **random** effect, which leads to a more satisfactory **situation** and thus becomes favored if repeated.

Reinforcement can be automatic, as for example in natural **selection** resulting in the multiplication of some genes in a **population** after a mutation, favorable in specific conditions. It has also been considered as a basic condition of animal or human **learning** by behaviorists. Devoid of its purely mechanistic taint, it is not rejected by so-called cognitivists, provided it be conjugated with recognition **memory**. (H.L. PETRI and M. MISHKIN, 1994, p.30-37).

In **learning**, according to these authors: "The role of reinforcement... is not to change the probability of a given **response**, but to lead to the development of expectancies about how certain **goals** can be reached" (Ibid., p.30). Reinforcement can possibly be used as a tool by **purpose** seeking systems.

The concept also can be extended to recognition **processes** in **automata** and, possibly to global **behavior** in **automata networks**.

→ **Hebb's rule**

2814

REJECTION REACTION¹⁾

Expulsion or neutralization by a system of **elements** coming from its **environment** and not compatible with the **maintenance** of its **dynamic stability** or **autopoiesis**.

The **elements** which are absorbed by the system may prove to be assimilable or not. A non compatible **element** cannot enter in the **functional cycles** of the system and may very well perturb or even destroy them.

However the systems possess various defensive devices depending of their **central control subsystem**, and whose specific **function** is to neutralize the perturbing **elements**. The best known is the immune reaction, but similar mechanisms seem to exist in any **complex system**.

The dysfunction of these mechanisms turns defenseless the system. However they themselves may become perturbing agents, when functioning in an faulty way. Allergies and anaphylactic reactions are examples of such negative results.

2815

RELATION¹⁾

"A property or properties of a **set** of **objects** and/or **events** that they do not have when taken separately" (R.L. ACKOFF & F.E. EMERY, 1972, p. 255).

These authors illustrate their definition as follows: "If John and Mary are married, then married is a property of the pair" (Ibid).

An other good example is water (H₂O) whose properties result from the chemical bond between two H and one O, while however inexistant if these atoms are not binded in the specific H₂O molecule.

Specificity implies that relations are necessarily *non-stochastic* coupled **interconnections**.

St. BEER refers to an "Axiom of Internal Relations" enunciated by HEGEL, according to which "... the relations by which terms are related are an integral part of the terms they relate" (1968, p.242).

It would possibly be clearer to say that any **element** acquires new polarities when it becomes **part** of a **set** or system. In effect, relations are in many cases only potential or intermittent.

The simplest relations are **dyadic**. However, many **dyadic** relations lead to the production of a third **element**, transforming the relation into **triadic**.

I.I. MITROFF and H.A. LINSTONE indicate that "... the number of possible relations among **subsets** in a system comprising only three **elements** is at least 49. In general, one has (2ⁿ - 1)² relations, where n is the number of **elements**. A system comprising ten **elements** thus may involve at least 1 million possible internal **relationships**" (1993, p.115).

As a result, many significant relations can easily be overlooked, particularly in very complex social systems. Those considered are not necessarily the most significant, according to BEER's following suggestive comment: "In practice however, we acknowledge relatedness only when we are ready to declare its **relevance**" (Ibid).

This implies a possible problem: In many cases, some relations exist, but, as **observers**, we do not perceive them. Moreover, **relevance** itself is a matter of **criteria**, not always clearly conceived or enounced and, in any case, relative to the **goal** we try to achieve.

The methodic search for meaningful relations and for meaningful **criteria** to be used in this search is without doubt one of the most important topic of systems research.

2816

RELATIONS Taxonomies^{1) – 2)}

J. WARFIELD resumes as follows the seven basic **categories** of relations, as established by A.De MORGAN in 1847 and adapted by C.S. PEIRCE around 1900:

- Empty (Null)
- Universal
- Reflexive
- Symmetric
- Asymmetric

- Hybrid
- Transitive

These **categories** are a fundamental basis, together with the six basic types of **relationships** for the **Generic Design Science** as proposed by WARFIELD (pers. comm.). He considers De MORGAN theory of relations as "a higher grade version of the theory of **sets**. Everything in **set** theory is incorporated in the theory of relations. However, the theory of relations allows the use of any kind of **relationship** in its formal **operation**, while the theory of **sets** only formalizes two types of **relationships**: **implication** and **exclusion**.

The theory of relations also leads to "**definition by relationship**", considered by WARFIELD as the highest grade of **definitions** (1988, p.336).

J. FEIBLEMAN and J.W. FRIEND list as follows the different kinds of relations which may exist between the **parts** of an **organization** or **elements** of a system:

- | | |
|--|-------------------------|
| (a) transitivity | (-a) intransitivity |
| (b) connexity | (-b) non-connexity |
| (c) symmetry | (-c) asymetry |
| (d) seriality (transitive, connected, asymmetrical) | (-d) aseriality |
| (e) correlation (one-many, one-one, many-one, many-many) | (-e) non-correlation |
| (f) addition | (-f) non-addition |
| (g) multiplication | (-g) non multiplication |
| (h) commutation | (-h) non-commutation |
| (i) association | (-i) non-association |
| (j) distribution | (-j) non-distribution |
| (k) dependence | (-k) independence" |

The authors add: "There may be other relations between **parts** in any concrete **organization**... But such relations do not bear on the question of **organization qua organization**" (1969, p.31-2).

(See entries corresponding to these different types of relations in their alphabetic order).

In a more common sense, the most frequent types of relations are: "**interaction, interconnection, coupling, linkage, cohesion, constraint, interdependence, function, organization, structure, association, correlation, pattern, etc...**" (G. KLIR, 1991, p.10).

KLIR also identifies **compatibility, homomorphism or isomorphism** (in **models**) and ordering.

Still from another viewpoint, a relation can be space-invariant, support-invariant or **time-invariant** (p.53-7).

2817

RELATIONS (Time-invariant)²⁾

G. KLIR proposes the following classification of these relations:

1. **Absolute relations**: "which are satisfied over the entire **time** interval of any activity of the given system.

2. **Relative relations**: "which are satisfied anywhere within a particular activity of the given system".

3. **Local relations**: "which apply only within some shorter time intervals of a particular activity" (1965, p.3).

Correlated to these different types of time-invariant relations, KLIR establishes three kinds of basic **behavior**: permanent, relatively permanent and temporary.

2818

RELATIONSHIPS¹⁾

J. WARFIELD characterizes as follows the six basic types of interpretive relationships used as a systemic basis for his General Design Science:

"**Definitive**: includes, is included in, implies, is a member of, is in the same **category** as...

"**Comparative**: is greater than, is heavier than, is preferred to, is of equal or higher priority with...

"**Influence**: causes, affects, aggravates, enhances...

"**Temporal**: must precede, follows, overlaps in time.

"**Spatial**: lies east of, lies above...

"**Mathematical**: is a function of, is computable from, is less than or equal to, affects the likelihood of...

"The brackets contain examples, but are by no means exhaustive of the set of possible relationships of each type" (1994b, p.60)).

2819

RELATIVITY POSTULATE^{1) - 3)}

"Any hypothesis valid for A as well as for B must be rejected if not valid for A and B together" (H.von FOERSTER, 1992, p.84).

von FOERSTER justifies his postulate giving as an example Ptolemean cosmography. Earthians and Martians could both believe their own planet to be the center of the planetary system, *but only in base of two different cosmographies*. However only the Copernican description is non-contradictory: "Every planet on its own and all of them together could move around the sun, without any logical contradiction: The heliocentric system validates the relativity postulate" (p.84).

This is indeed a very interesting conceptual generalization of physical relativity.

2820

RELATOR¹⁾

"A **sign** that relates the signification of one **sign** to that of another" (R.L. ACKOFF & F.E. EMERY, 1972, p.175).

According to ACKOFF and EMERY, a **relator** may attribute a property to a pair that cannot be attributed to either member taken separately. It also may introduce comparisons, either qualitative or quantitative.

2821

RELATORS (Arithmetic)²⁾

A formalized **language** based on arithmetics, whose aim is to modelize a great variety of systemic **dynamics**.

This **language** has been elaborated in France by a number of researchers under the leadership of Th. MOULIN at the "Ecole Nationale Supérieure de Techniques Avancées" (Groupe de recherches SYSTEMA).

As an example, MOULIN applies the **model** to neuronal systems. He writes: "Our long term purpose is to find a relation between "parallel" **descriptions** associated to **morphogenetic** potentials and "sequential" **descriptions** which fix at several **levels** the "elements of displacement" and, consequently the **dynamics**. This relation would integrate linguistic and informational aspects and would generalize the classical flux-strength equations" (Groupe Systema, E.N.S.T.A, 1988)

The **models** seems to have a potential for numerous applications. They are however quite abstract and the proposal should be studied directly from the sources.

2822

RELAXATION¹⁾

The return of a system or **process** to **equilibrium** after a **disturbance**.

This **behavior** is a characteristic of **dynamic equilibrium**, or **homeostasis**, when the admitted variations remain within a closed **basin**.

2823

RELEVANCE^{1) - 3) - 4)}

The character of something which is related to, or pertinent, in relation with an investigated **issue**.

Elements, events, environment are considered relevant for a system if, at least in some cases and sometimes, they exert an influence on its **behavior**.

Of course, **criteria** of relevance are defined by the **observer** and his/her specific viewpoint. They are thus never absolute and, in many cases, may even be illusory.

From a systemic viewpoint, we could tentatively distinguish:

Underconceptualized relevance: Relevance is considered only from a very narrow viewpoint by an individual or a small group merely interested in an ill-understood and/or ill-conceived circumstantial and very limited **issue**. In most

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

cases no serious research is done, or taken into account. In some, serious (or spurious) research may even be used as an ad-hoc tool to further some dubious **objective**.

This type of viewpoints is very common in day-to-day politics.

Broad relevance: Relevance is considered in a **long term** and wide embracing perspective. This supposes a clear definition and a broad **inquiry** about the system considered and also of the motives, expectations and **goals** of all the **stakeholders**. However, research excessive in scope and in time may lead to procrastination.

In big **issues**, as for example great public works, the **limits** of relevance should be clearly defined, justified and explained.

Overconceptualized relevance: Relevance is considered in such a vast space and time perspective that it becomes... irrelevant for any practical **purpose**.

In such cases, red-hot **issues** may remain unattended while spurious research and abstract debates linger unconvincingly on.

A good **understanding** of systems and their conditions of existence and **survival** is instrumental in defining **criteria** of relevance at any **level**.

On the contrary, the lack of appreciation of the relevance of some **events** or **elements** for a given system leads to unwarranted **simplifications** and, at times, very costly **errors**.

→ **Underconceptualization; Invisibility**

2824

RELEVANCE (Criteria of) ¹⁾³⁾

The **elements**, or **issues** that are relevant in the **management** of any kind of **situation** should be carefully evaluated through a study of the nature of their impact and the intensity of the same.

This implies a systemic -cybernetic **inquiry**.

On the other hand no such inquiry can totally escape from personal prejudice. As a result, the aspects taken in account must be also scrutinized from that viewpoint. Very interesting ways to avoid **underconceptualization** are by using techniques of **generative dialogue** in **design conversation** (B. BANATHY), **interpretive structural modeling** (J. WARFIELD), or **interpretive systemology** (H. LOPEZ GARAY and R. FUENMAYOR)

In all cases, **conversation** and **consensus** are needed to avoid dubious and/or excessively subjective **evaluations** about the different aspects taken (or not taken!) into account. But, of course, strictly objective criteria of relevance cannot be established. In fact, it seems that we are still in want for a good theory of relevance (D. HOFSTADTER, 2000, p. 50-51)

RELEVANT SYSTEM

→ **System (Relevant)**

2825

RELEVANCE of a model ^{2) - 3)}

Character of a **model** "well adapted in relation to some finalities that can be explicitated" (J.L.LE MOIGNE, 1977, p.13).

LE MOIGNE opposes "relevance" to "evidence" and quotes the following comment by P. DELATTRE: "It is by way of what we ignore that slogans become inserted into us (the "evidences") which, by dint of repetitions, bring us the certainties that our mere **knowledge** could not justify" (1971, p.22).

The concept of "model relevance" is closely linked to the one of "**idoneity**", proposed and widely explored by Ferdinand GONSETH (1945, p.57-67).

The comparison of the concepts of relevance and evidence decisively relativizes DESCARTES first principle, as stated in his "**Discourse on the method**".

2826

RELEVANCE TREE ANALYSIS ²⁾

"A technique... based on the general principle that, in any **hierarchical situation**, the **norm** for **parts**-performance is system-performance" (E. LASZLO, 1974, p.126).

While this **Systems Analysis** technique thus defined by E. LASZLO implies a good ordering principle, it does not inevitably mean that the global system performance **norms** are sound... in which case the technique may be wrongly used.

2827

RELIABILITY (Interrelated)

→ **Venn diagrams**

2828

RELIABILITY in dynamic terms ¹⁾⁴⁾

The reliability of physical or mechanical systems follows a characteristic curve in time. The **curve** includes three successive regions:

- the early or "youth" period when the systems have a high, but swiftly declining failure **rate**, as a result of the quick elimination of those who were defective because of some construction fault
- the useful **life** period when the failures are at their minimal **level**, during a quite long **time**, as the defective systems have been eliminated
- the **breakdown** period, when a quickly growing number of systems fail due to **wear** and aging

Of course, at each stage, reliability can be tested through appropriate methods.

An intriguing question mark is if and how this concept of reliability could be applied in the case of human systems: enterprises, political systems, or cultures among others

→ **Automata (Reliability of); Redundancy**

2829

RELIABILITY of a machine ^{1) - 3)}

An evaluation of the capacity of a **machine** or system to functionally survive the **breakdown** or impairment of some of its **parts**.

In parallel or **neural networks** and generally in complex systems, the breakdown of some **elements** or some unexpected **inputs** do not usually inhibit seriously the system's capacities, or limits only slightly its operative power. This is because computing or **operation** is *distributed* in the **whole** of the parallel **network**, which is considerably **redundant**.

However, when disabled, the **network** must undergo a reorganizing **process**, in order to create new internal **connections** to replace those which have been destroyed. A good example is the reconstruction of physical abilities and **knowledge** in persons which have been affected by a not overly destructive cerebral haemorrhage.

The subject of global reliability in neural computation based on unreliable **components** has been first considered by J.von NEUMANN (1956).

2830

RELIABILITY of a System ¹⁾²⁾

The measure of the **probability** that a system will perform some requisite function within specified conditions and during a specified **time**.

This measure is basic for **risk analysis** and **forecasting** applied for now mainly to physical and mechanical systems.

It includes a statistical and **prospective** study of possible causes of failures.

2831

RELIGION : A systemic view ¹⁾⁴⁾

Many authors have insisted on the etymology **meaning** of religion: re-ligare which means basically "interconnect".

From such a viewpoint, religion is a typical systemic social device, of a universal character.

All religions creeds, of whatever kind, offer similar characteristic traits:

- offering a set of **beliefs**, **values**, commandments, myths, ritual practices and standardized **behaviors**
 - imposing them as conditions to become and remain a member of the religious brethren
 - excluding as "heretics", "infidels", or "renegates" those individuals who do not adhere to or do question the credo
- It is thus clear that:

- the basic **elements** of any credo lead to an also basic psychological **similarity** among millions of individuals
- such uniformity fosters a sense of **community** membership in the thus conditioned individuals
- the shared credo creates specific **community structures** and ushers ordered collective behaviors
- those individuals who do not share the credo are generally excluded from the community and easily become rejected outcasts and may even be killed.

On the other hand, the existence of different religious **groups** of such characteristics explains rivalries, proselytism, fundamentalism, fanaticism and **culture conflicts**

2832

REMODELING ²⁾ - 4)

"The replacement of the existing **frame** of thinking with a newly-articulated **frame**" (J. WARFIELD, 1989a, p.9).

This **process** is also called "**framebreak**" by WARFIELD, who considers it essential to diminish and if possible eliminate **underconceptualization**, specially in the understanding of **complex systems** (Ibid).

WARFIELD proposed a technique for remodeling, whose aim is to enlarge as much as possible the mental outlook of the participants (1989 b, p.39-41).

→ **Revalidation**

2833

RENORMALIZATION GROUP TRANSFORMATION ²⁾

A transformation that ensures **self-similarity** of a **function** at different **levels**.

(See "**Self-similarity in the WEIERSTASS function**")

2834

REPAIR ¹⁾

"Replacement of a **part** of a **structure** either by a structural replica or a functional equivalent" (O.R. YOUNG, 1964, p.76)

In living and generally social systems, repair is automatic within limits, through autopoiesis.

→ **Breakdown; General Adaptation Syndrome; Maintenance**

2835

REPEATABILITY ¹⁾

The possibility of reappearance of some characterized **context** or **situation**, as perceived by an **observer**.

G. BATESON considers "The conventional assumption that **context** can be repeated, at least in some cases ... as a cornerstone of the thesis that the study of **behavior** must be or-

dered according to the Theory of **Logical Types**... Without the assumption of repeatable **context**... it would follow that all 'learning' would be... **zero learning**" (1973, p.259).

Of course, repetition of **context** is never perfect. It is only indispensable that it be sufficiently repetitive to allow for anchoring a useful **understanding** of some observed **phenomena** or for some **behavior** coherent with formerly learned properties of the **context**.

2836

REPELLOR ²⁾

Any active **behavioral limit** where a system tends to backtrack toward a more balanced **dynamic equilibrium**.

R.H. ABRAHAM and C.D. SHAW use this **model** in their **topological representation of self-organization**. Repellers are in fact **separatrices** considered as dynamical features in **attractors** (1987, p.550).

"Repellor" could also be considered a near synonym for **critical threshold**.

2837

REPertoire (or REPERTORY) ¹⁾

A set of possible **patterns of behavior** in a system.

Repertoires are learned and slowly become fixed as the system matures. They then form the base for **dynamic stability maintenance**. They are limited in accordance with:

- the basic nature of the system, reflected in its **organizational closure**;
- The way the system interacts with its specific **environment** during its **learning period**. (See for example "**Knowledge construction**").

2838

REPLICATION ¹⁾

The direct or cyclical **production** of **elements** in a system or a **population**.

The reproduced **elements** may be similar to or different from the initial ones. But all must be compatible with the system to which they pertain.

For M. EIGEN, replication is the condition for the shaping of **populations**, from which different types may form **quasi-species**, each time that some **error threshold** is crossed during replication.

From another viewpoint, V. CSANYI writes that, in order to operate replication: "... the constructor needs a **description**, the **information** necessary for the copying **process**. The essence of replication is the **function** of copying regardless of the particular mechanisms of **storage** and retrieval of **information**. It does not matter whether this **information** is stored separately (as in the case of DNA for example) or is distributed in the **whole** system (as in **society**)".

CSANYI also distinguishes **temporal replication** "as the continuous renewal of the system in **time**... (in a way) sufficient to maintain the unity and **identity** of the system and its **organization**"; and **spatial replication**, in which: "the system produces its own copy, which becomes separated from it in **space**" (1993, p.262). This is for example the case of cellular reproduction.

The first case corresponds to **autopoiesis**, while the second accounts for the **growth** of **populations** of some specific type of system, as cells or amoeba.

According to V. CSANYI and G. KAMPIS: "Replication is an imperfect copying of the **components** directed by **information** (that is) located... in the **component** itself or is distributed within the system" (LASZLO, 1991).

This is practically equivalent to **autopoiesis** and to **hypercycle** reproduction.

Any system needs an **autogenic** precursor, whose characteristics reflect a specific combination of **information** received from former systems.

The authors call "**zero-system**" such a not yet developed **network of components** (G. KAMPIS & V. CSANYI, 1986).

→ **Archetype**

2839

REPLICATOR ¹⁾ - 4)

Any **element** "able to create copies of itself" (R. DAWKINS, 1992, p.16).

DAWKINS writes: "Think of the replicator as a mould or **template**" (Ibid) and he proposes the following construction **rules**:

- there is an abundance of diverse types of building blocks around the replicator
- each building block may have an affinity for its own kind, - or possibly for some other specific kind - situated somewhere in the replicator

As a result, they may be able to attach themselves "in a sequence which mimics that of the replicator itself" (p.17).

Crystals are replicators.

Replication also exists, in different forms, in **living systems**: DNA - amoebas - cells. It would be interesting to study the public opinion **phenomenon** from the same viewpoint. The Swiss engraver A. BÖCKLIN produced in the 19th Century a print suggesting precisely this.

Replicators can be modeled as **automata**. For the time being, such automata are still **computer models**, whose concept developed out of von NEUMANN's model of **cellular automaton** known as "universal constructor". The state of the art has been described recently by M. SIPPER & J.A. REGGIA (2001)

The possibility to create material **self replicating automata** seems to become real and is related to the so-called **Artificial Life**

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

For an interesting comparison between **memes** and **genes**, both considered as replicators, see S. BLACKMORE (2000, p. 56-8)

→ **Fitness function; Paralled Distributing Processing; Synaptic Weights**

2840

REPORTING DENSITY²⁾

→ **Venn diagrams**

2841

REPRESENTATION³⁾

1) "A **set of signs** for **communication** of the features of some **entity** or system" (J.Z. YOUNG, 1974, p.298).

2) "Any **structure (pattern, picture, model)** whether abstract or concrete, of which the features purport to symbolize or correspond in some sense with those of some other **structure**" (D. Mac KAY, 1969, p.161).

3) "A **set of concepts and rules** that must be used in creating a **description** from a certain point of view, or from a certain **class** of points of view that are equivalent with respect to some conditions, that are characteristic of the representation" (G. DALENOORT, 1989, p.15).

4) The result of our ways to observe reality and construct **models** of it (inspired from J.J. GIBSON).

The definition by YOUNG shows that the production of any type of **model** depends on the type of **code** being used. A representation is thus senseless for someone who ignores the **code**.

Mac KAY adds the following comment to his definition: "The physical **processes** concerned in the formation or **transformation** of a representation are thus distinguished from other physical **processes** by the **element of significance** which they possess when conceived as representing something else."

"For any given **structure** there may be several equivalent representations, defined as such through possessing certain abstracts features in common" (Ibid).

Mac KAY's concept of representation is practically equivalent with the systemic concept of **model**.

According to DALENOORT: "Whereas the term '**description**' usually refers to a single system or **model**, the term 'representation' refers to **classes** of systems, and the characteristics of the **set** of concepts and **rules** involved" Moreover he distinguishes:

- **causal** representations versus **goal-directed** representations, and

- representations according to different **levels of aggregation**" (Ibid., p.15).

J.L.LE MOIGNE quotes J. LADRIERE: "In representation there are, as to say, two types of presence: the effective presence of a person, an **object**, an **action**, and the indirect presence, mediated by the former, of a reality that does not belong to the **field of direct perception**" (1977, p.45).

J.L.LE MOIGNE adds that what he calls "**systemography**" aims at "representing the **object** as significant and as a functioning **organism**" (Ibid). In other words, any representation is an "ad hoc" **observer's** representation.

The problem of representation raises very difficult **epistemological** and **ontological** questions. J.J. GIBSON, for instance, who proposed an **ecological** approach to (visual) **perception**, even states that: "The efforts made by philosophers and psychologists to clarify what is meant by a *representation* have failed, it seems to me, because the concept is wrong... (A picture) is not a substitute for going back and looking again. What it records, registers, or consolidates is **information**, not sense **data**" (1986, p.280).

Of course, it becomes **information** and, as such, can be modified by further **observation**, because of the capacity for interpretation by some **observer**, in his/her own terms, thus "making sense" of it.

On the question as if we are somehow able to reach reality through our constructed representations of it, F. BONSACK states:

"First of all we must avoid the trap implicit in the **ambiguity** of the term 'representation'. What is a representation? The global and instantaneous **perception** that I have at this moment of the scene that surrounds me? The succession of **perceptions** that I obtain by inspecting successively details of this scene? The checkings that I may perform by a closer inspection, by manipulating or testing some of the **objects**? or yet, the organized **models** of the world that I construct myself, in order to integrate, organize and interpret as a coherent **whole** all these instantaneous **perceptions**, together with all those about which I received indirect **information**?"

"If we say that we have access only to representations, it may be suggested that a representation is its own measure, that it can be verified only by comparing it to another representation – which is not really a verification, as both are prejudiced in the same way. However, such is not the case if we take in account the different possible **levels** of representation. I am able to correct a first global **perception** by focusing my attention upon certain details; by manipulation and testing I may correct my world's image if it is not compatible with certain new experiences obtained either by global instantaneous **perception**, or in detailed **perception**, or because I have conducted some more or less sophisticated manipulations.

"Thus, my **criterion** is not merely the inter-subjective **consensus**, it is firstly and mainly the correspondence of this different **levels** of representation. I may well concord with the overwhelming majority about a geocentric model of the world, but this will not curtail new discovery, or a new interpretation of known **data**, which show that such a **model** is not the best and that another one is simpler, more coherent and more fruitful. The decisive coincidence is not between theoretical discourses or even descriptive ones of the scientist. It is between what this discourse predict and which is effectively perceived through experience" (1990, p.155-6).

In any case, and to put in a simple way as done by A. KORZYBSKI: "The map is not the territory" (which does not mean, of course, that the territory does not exist. And, as noted by A.L. GOUDSMIT: "... external world and internal representation are assigned different Russellian logical types" (1989, p.169).

Synthetically, any **consensus** – at least any scientific one – needs to pass POPPER's falseability test, again and again. It could be said however that the nature and **idoneity** of such tests is again a matter of **consensus** among scientists. Thus, our conclusions are still... inconclusive and probably will remain inconclusive for ever: a "decisive" coincidence is not necessarily a definitive one.

2842

REPRESENTATION (Active or latent)³⁾

Active representation, according to Fr CRICK and Ch. KOCH is the **process** of explication of an implicit representation present in our neural **network** and evoked by some **perception**, through a **pattern** of firing neurons.

These authors write: "A latent representation of a face must also be stored in the **brain**, probably as a special **pattern** of synaptic **connexions** between neurons... For example, you probably have a representation of the Statue of Liberty in your **brain**, a representation that usually is inactive. If you do think about the statue, the representation becomes active, with the relevant neurons firing away" (1992, p.112).

Of course, there is still a need to explain how these latent representations become established, through some initial **perception**, internally transformed and made available for retrieval.

In R. FISCHER words, who applies the notion to **parallel distributed processing**, "... what was learned is not a representation, but the **state** of all... **neuron-like connections**" (1992, p.212).

This is the latent representation capacity, out of which we may at will obtain instant representations of what we "know", according to what and how we "know".

2843

REPRESENTATION ARTEFACT²⁾ - 3)

Any feature in a **model** that does not correspond to some characteristic of the **concrete system**.

This concept is introduced by D. GERNERT, who writes: "When systems of the real world are modelled on the basis of a finite **scheme** of representation, some **phenomena** may occur which are relevant only within the **model**, but have nothing to do with the underlying system..."

"In representing a function by a J. FOURIER expansion the well-known Gibbs **phenomenon** may appear, which means that there are peaks in the representation that have no counter part in the original function" (1994, p.126).

Representation artifacts are produced by some implicit feature of the **model** itself and pass easily unnoticed. This may lead to subtle errors, very difficult to discover.

→ **FOURIER analysis; Random walk**

2844

REPRESENTATION (Complex)¹⁾ - 4)

Fr. CRICK and Ch. KOCH state: "An **object**... may be represented in more than one way - as a visual image, a **set** of words and their related sounds, or even as a touch, or a smell. These different representations are likely to interact with one another. The representation is likely to be distributed over many neurons, both locally... and more globally" (1992, p.112).

One wonders if the same could be true in social **networks**: A social group or a culture could have complex global representations distributed through numerous interacting individuals, who would be quite unaware of the existence of a global representation. So-called "Public opinion" could be such a collective and complex representation.

2845

REPRESENTATION (Explicit and implicit)³⁾

According to Fr. CRICK and Ch. KOCH: "It is important to distinguish between an explicit and an implicit representation. An explicit representation is something that is symbolized without further **processing**. An implicit representation contains the same **information** but requires further **processing**. The **pattern** of colored dots on a television screen, for example, contains an implicit representation of **objects** (say, a person's face), but only the dots and their locations are explicit. When you see a face on the screen, there must be neurons in your brain whose firing, in some sense, symbolizes that face" (1992, p.112).

In other words, **patterns** of perceived **signals** acquire **meaning** only if we already have established internal neural **patterns** more or less in **resonance** with that which we perceive. Such **patterns** have necessarily a genetic base

and were constructed on this base by **learning**. Moreover, **learning** differs with social and cultural settings, which explains that similar **perceptions** may lead to different representations in different persons.

2846

REPRESENTATION (Quantal)³⁾

Mac KAY states: "Representations communicable in a two-valued (yes or no) form are necessarily **quantal** in **structure**, since an "imperceptible **change**" in a two valued logical form is by definition meaningless. All the **changes** are discrete, therefore the elementary concepts of logical representations are discrete and enumerable..."

"In general, a **pattern** reduced to such fundamental terms will contain a certain number of distinguishable groups or **clusters** of **elements**, the **elements** in each group being indistinguishable among themselves. There are thus two numerical features of interest:

- 1) The number of distinguishable **groups** or **clusters** of indistinguishable **elements** in a representation, and
- 2) The number of **elements** in a given **group** or **cluster**" (1969, p.164).

Thus, quantal representation can generally be matricial.

2847

REPRESENTATION (Structure of)³⁾

HEYLIGHEN states: "How **distinctions** are made (i.e., which **distinctions** out of the infinite number of potential **distinctions** are selected), and how they are connected, will determine the **structure** of a representation and, hence, its adequacy in predicting the observed **behavior** of the system" (1990a, p.427).

The built up of any representation is necessarily based on perceptive conditioning as well as perceptive intentionality. This is the global lesson of **ethology** (von ÜEXKÜLL, LORENZ and their successors) and of **phenomenology** of **perception** (von BRENTANO, von WEIZÄCKER, KÖHLER, KOFFKA, MERLEAU PONTY and others).

2848

REPRESENTATION SYSTEM²⁾ - 3) - 4)

Any **observer** must necessarily construct for himself a **set** of **rules** for the interpretation of whatever he perceives. In nearly all cases, this mental **structure** (or **cognitive system**) remains tacit, and even unconscious, while the **observer** thinks that he is applying the "natural laws of intelligence" and obtaining the **knowledge** of "reality".

In fact there are many representation systems, which are individual variants of great collective systems of cultural origin.

As shown by von FOERSTER, H. MATURANA and F. VARELA, every **observer** constructs his/her own representation system, which moreover are interdependent: "I exist through the others and they exist through myself; we are our reciprocal **feedbacks**" (H.von FOERSTER, 1992, p.85).

Representation systems can be rooted in myths, in some religious belief, in a philosophical system, in an ideology or in a scientific **paradigm**, for example. In some cases, they may present individual or collective pathological variants (personal or mass paranoia).

The present planetary **transculturalization process** tends to make manifest the existence, nature and characteristics of the various culturally grounded representation systems. (see for example MARIYAMA's work on **mindscape**s).

The necessity to understand and manage the numerous complex situations now created by man himself has given rise to a new representation system, the systemic one, which has been explored as such by authors like C. WEST CHURCHMAN (1971), H. SIMON (1969) and J.L.LE MOIGNE (1977).

LE MOIGNE writes: "The representation system... transforms the **object** to be modeled into a transmissible **model**". He proposes his "**Système Général**" concept "as a representation system for organized **complexity**" (1977, p.55-58).

2849

REPRESENTATIONAL SYSTEM²³⁾

The extensive and interconnected **set** of **images**, **models** and **concepts** used by an individual as a **categorizational** tool and general **reference frame** for observational and behavioral **purposes**.

Such a system can be considered as a **representation system** in **activity**, as it is always **used** to observe and describe **events** and **situations** to oneself and guide **behavior** and **action**. The effective use of a representational system implies thus **intentionality**.

It should be clearly distinguished from any **systems representation**, which is a specific **model** of a **part** of the observed world, constructed in accordance to **systemics**, which is in itself a quite general representational system.

→ **Affordance, Knowledge (Implicit); Perception**

2850

REPRODUCER¹⁾

"The **subsystem** which carries out the instructions in the genetic **information** or charter of a system and mobilizes **matter**, **energy** and **information** to produce one or more similar systems".

The reproducer is one of the **20 critical subsystems** in J. G. MILLER's **taxonomy of living systems** (1978, p.3).

2851

REPRODUCTION^{1) - 2)}

"Production by an **object** x1 of class X of an **object** x2 also of class X" (R.L. ACKOFF & F.E. EMERY, 1972, p.22).

Reproduction should not be confused with **self-reproduction**.

ACKOFF and EMERY observe that reproduction occurs many times through coproducers, which they define as: "Two or more **objects**, properties and/or **environments** that are producers of the same product" (Ibid., p.23). This becomes closer, but not identical, to **autopoiesis**. Sexual reproduction for instance, can be considered an **autopoietic mechanism**, but then only at the **species level**.

As observed by H.T. ODUM, **error-free** reproduction has a **cost** and, moreover becomes impossible in the long run, at least as to the **elements of complex systems** (1971, p.142).

The case of practically eternal correct reproduction of amoebas or bacteria remains a puzzle: Why does division, leading to total separation, maintain some kind of **identity** without limit in time, while **autopoietic complex systems** are always finally doomed to destruction?

2852

REPRODUCTION (Self)^{1) - 2)}

The ability of a system to maintain its **identity**, in spite of the progressive replacement of its **elements**.

This concept, practically equivalent to **autopoiesis**, was enounced in 1951 by J.W.S. PRINGLE in these terms:

(An open system) "has the following properties:

1. It is a **steady-state equilibrium**, each unit appearing to be constant only because it is being formed and destroyed at the same rate;
2. Either or both **processes** are subject to **variations**;
3. The **rate** of formation and the **rate** of destruction of each unit depend on different **functions** of the quantity present, and on the **environmental** conditions.

"These features imply a property of the units which may be called **"replication"**; that is, the presence of a unit in the system causes more similar units to appear, with an accompanying increase in **order** which is balanced at **steady - state equilibrium** by the decrease in **order** involved in their destruction" (1956, p.92).

Self-reproduction is one of those ambiguous terms in cybernetics and systemics. W.R. ASHBY, who died before the **autopoiesis concept** was fully explored, could write in 1962: "... be-

fore we start to consider the question of the self-reproducing system, we must recognize that no **organism** is self-reproducing" (1981, p.72).

His argument was that the **reproduction** of a system could never occur without a mobilizing **interaction** with some other system or with a specific **environment** and stated that "the adjective **"self-reproducing"** is highly objectionable **semantically** and logically" (p.72).

This did not deter him to dedicate his paper to the "Self-reproducing system". He came to the clear conclusion that self-reproduction terminology should be used only for **cyclical processes** of the type "A reproduces B, then B reproduces C, and then C reproduces A" (p.78) and recognized that "Such a **cycle** is of course extremely common in the biological world" (p.79)... where "All sufficiently large systems will become filled with self-reproducing forms" (p. 79).

Thus, genuine self-reproduction is always an **endogenous process**, and the **exogenous** production of a **whole** copy or the original system, as for example in some of J.H. CONWAY's Games of Life, should not be called self-reproduction, as it depends of an **algorithm** external to the original **configuration** itself, which, by the way, is also the case in biological (not self-) **reproduction**.

ASHBY was, after all, on his own way toward **organizational closure** and the **hypercycle**.

2853

REQUISITE HOLISM (Law of)

→ **Holism (Law of Requisite)**

2854

RESCUER^{1) - 5)}

A system (**exogenous**) or **subsystem** (**endogenous**) that helps a system to recover from some **disturbance** dangerous for its **survival**.

This concept has been introduced by L. SKYTTNER, inspired by the **survival** conditions at sea (1992, p.6).

He gives as examples: lifeboats, dinghies, communication equipment, **survival** equipment, ship surgeon, radio-officer.

A rescue (**sub**)system depends on the existence of **reserves** or **resources**, on a specific capacity to receive, decode and use **information**, through suited existing **channels**. It may be a part of the system, or possibly a separate system created to be able to rescue a member of "confederate" systems, when needed. An example of this last is the Red Cross.

→ **Allopoiesis**

2855

RESEARCH (2nd. Order)¹⁾²⁾³⁾

Second - order research is research on the research **process** itself. Its importance for the improvement of research **methodology** has been stressed by G.de ZEEUW, R. GLANVILLE and various members of the **Systeem Groep Nederland**.

In any type of research, **observation** implies unavoidably some kind of intervention. This is the case in micro-physics, as stated by HEISENBERG with his **Indeterminacy Principle**. But it is also true in psychotherapy for instance.

R. GLANVILLE writes: "We intervene in the (observable social) **object**. We change how it behaves by acting on it" and "We intervene in observing. We intervene both in how we observe and how we think of our observations (for instance, seeing observations as observables)" (2002, p. 110)

GLANVILLE adds: "We probably intervene in order to cope with unwanted **side effects**, **errors**, etc..., so we become more likely to get higher-quality observations" ... (Ibid)... and "The improvement lies in the conditions that lead to observations. Making observations of improvement gives new observables and new **observers**. We complete the chain: circulate; re-enter" (Ibid, p. 111)

D.P. DASH describes this process as follows: "In de ZEEUW's scholarly writings, research has been viewed as a developing **narrative**" (2002, p. 115). Research leads to "contact with greater and greater **variety of disturbances** and this creates a strain on the basic script on which the narrative of research in that field is based" (2002, p. 115)

In short, 2nd order research implies upgrading observation and research through observation of research itself. It is thus a cybernetic process based on recurrent **feedbacks**.

→ **Organizational closure; Problem solving; Underconceptualization**

2856

RESEARCH AND DEVELOPMENT¹⁾

The set of activities that tends to translate pure scientific knowledge into practical applications.

The aim of R&D is basically to create workable techniques out of general scientific principles. For instance, organic chemistry led to the production of many artificial derivatives of organic molecules, and genetics is now leading to genetic engineering.

R&D is however not much concerned with **side-effects** of its creations, because it is basically profit-oriented. In many cases - and more and more so - the **side-effects** are noxious or even catastrophic. Thus, from a systemic **viewpoint**, R&D should be re-framed in a more global perspective in order to forecast and take care in due time of possible negative effects.

2857

RESEARCH (Pre-systemic)^{1) - 3)}

I. BLAUBERG et al thus characterize pre-systemic research: "Investigation consisted mostly in 'decomposing' the **object** under study into **parts** and in their qualitative **description**, assuming that it was possible to construct a unique and exhaustive theoretical **model** of the **object** that would not depend on the problem being solved or on the methodological apparatus used" (1977, p.119).

In comparison with this method: "The **system approach**... proceeds from the fact that the specific features of an **object** (system) are not exhausted by the peculiarities of its constituent **elements**, but are rooted first and foremost in the character of the **connections** and **relations** between its **elements**. Moreover, a complex **object** is usually a hierarchical poly-structured and **multi-level** formation whose various aspects are studied by different sciences" (Ibid).

Two basic aspects of the **systemic methodology** thus appear: The need to avoid severing significant **connections** and the need for reciprocal **understanding** between disciplines by the use of suitable **models** of these **connections**.

2858

RESERVE^{1) - 2)}

Some quantity of **energy**, **matter** or **information** stored within a system, which could be eventually used.

The notion of **counter-aleatory** reserve has been introduced by P. VENDRYES (1942) who understands that the existence of adequate reserves is a sine qua non condition for the **autonomy** and even the **survival** of any **living** or **social system**, because no **regulator** has any counteracting power against **disturbances** if it does not dispose of ad hoc means.

This notion is somehow related to ASHBY's **law of requisite variety**.

As **regulators** act in order to maintain the internal **organization** of the system, it is also clear that the existence of internal reserves is a basic condition for **organizational closure** and **autonomy** in the sense proposed by H. MATURANA, admitting of course that the storing of the types of reserves proper to the system is itself conditioned by that same **autopoietic** property.

However, to store reserves, the system must to begin with, import them (and select them, and transform them), always in accordance with its (**autopoietic**) nature. The point is made by W.R. WINBURN, who writes: "The internal **structure** of the system determines its **representation** of the **change** such that we say that it is "**closed to information**". Yet the causal **process** behind this determination requires us to view the system as "**open to matter and energy**". **Energy** is imported and **dissipated**, but

also stored through internal **processes** (usually **metabolic**) defining a **negentropic** reserve. A sensed **change** may trigger this reserve into an extended release of **energy**, thereby producing complex **nonlinear behavior**" (1991, p.558).

2859

RESILIENCE^{2) - 4)}

The capacity of an adapting and/or evolving system to bounce back to **dynamic stability** after a **disturbance**.

In a more general meaning, resilience includes the system's ability to create new conditions of **fitness** for itself whenever necessary.

C.S. HOLLING describes resilience as: "... the ability of a system to maintain its **structure** and **patterns of behaviour** in the face of **disturbance**". He adds: "The size of the **stability domain** of residence, the strength of the repulsive forces at the **boundary**, and the resistance of the **domain** to contraction are all distinct measures of resilience" (1986).

He also observed: "Resilience determines the persistence of **relationships** within a system and is a measure of the ability of this system to absorb **changes** of state **variables**, driving **variables**, and **parameters**, and still persist. In this definition, resilience is the property of the system and persistence or probability of extinction is the result" (1976, p.83).

This condition is as well formulated by T.F.H. ALLEN and T.B. STARR: "The ability of a system to maintain its **structure** and general **patterns of behavior** when displaced from its **equilibrium condition**" (1982, p.276).

These authors add: "More resilient systems are those which can return to an **equilibrium condition** despite large displacement" (Ibid).

Resilience should thus not be confounded with **dynamic stability**, even if the latter is generally recovered as a result.

Resilience is in a trade-off relation with **stability**: *some limited instability* is a favourable **survival** condition.

Resilience may be greatly reduced or even suppressed when a system is driven too close to a **threshold of instability** by excessive pressure. This has been for instance frequently the case after overfishing of some marine or lake species: the **population may collapse irreversibly**, even if the excessive pressure is belatedly lifted.

However, within reasonable **limits**, as stated by W.D. GROSSMANN and K.E.F. WATT: "Systems will develop resilience and maintain it only if the **environment** of the system continually confronts the system with varying challenges. Resilience thus evolves in a way similar to human **immune capabilities**" (1992, p.16).

The same authors also state that: "... **complexity** is one prerequisite for resilience" (p.22).

In this way the notion of resilience is connected to ASHBY's **law of requisite variety**: no variety, no resilience... and no **viability**.

C. HOLLING states: "There are two resilience measures: Since resilience is concerned with probabilities of extinction, first, the overall area of the **domain of attraction** will in part determine whether **chance** shifts in **state variables** will move **trajectories** outside the **domain**. Second, the height of the lowest point of the **basin of attraction**... above **equilibrium** will be a measure of how much the forces have to be changed before all **trajectories** move to extinction of one or more of the **state variables**" (1976, p.86).

G. BROEKSTRA writes: "The new **fluctuation paradigm** views **organizations**... as instances of stable **chaos** or coherent spots of **vorticity** in a turbulent background... It implies the recognition that resilience rather than **stability** is crucial for the organizational **survival** and that resilience implies that the **organization** is generally far from its **equilibrium state**" (1992, p.1028).

As also noted by BROEKSTRA, "...all **fits** are only temporarily effective" (p.1029).

HOLLING has observed that there is a kind of trade-off between resilience and **productivity**. The latter can be increased, and even much increased, allowing for a loss of resilience, and conversely. At the **limit**, as stated by C. HOLLING and M. GOLDBERG, it becomes a matter of changing "...the emphasis from maximizing the **probability** of success to minimizing the chance of disaster. It shifts the concentration from the forces that lead to convergence on **equilibrium** to the forces that lead to **divergence** from a **boundary**. It shifts our interest from increased **efficiency** to the need for resilience" (1971).

2860

RESISTANCE (Acquired)¹⁾²⁾

An adaptive and evolutive **process** which allows a system to successfully fight the **effects** of some dangerous **input** from its **environment**.

Three very important examples are:

- acquired immunity of numerous pathological micro-organisms to a growing number of antibiotics
- progressive appearance of many new strains of insects able to resist the effects of numerous chemical insecticides.
- the progressive immunization of whole human **populations** against some infectious diseases. This seems to have been the case with plague in Europe from the 14th Century on. (However, such immunity may be lost after long **periods** without new **epidemics**).

Acquired resistance is a systemic **phenomenon** showing the shifting **equilibria** - through **adaptation** and **evolution** - in the **interrelations** of systems of different kinds.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

The lack of understanding of acquired resistance becomes a critical deficiency in situations of accelerating **change** proper to our time of massive technological **evolution**.

An exploration of possible similar **phenomena** in societies could be interesting.

2861

RESOLUTION LEVEL ^{1) - 3)}

The level of discrimination used by an observer to study an **object** or a **concrete system**.

By means of appropriate instruments, for example various types of microscopes, an **observer** can obtain different resolution degrees, which could not be obtained by the use of his or her physiological senses only.

R. VALLÉE states: "Many of the **concepts** of the systems theory depend on the **observation process**" (1990, p.54), i. e. the resolution level, a notion emphasized by this author in his paper.

Many "**boundaries**" (for example, the skin of an animal) reveal themselves to be in fact complex **interfaces**, when the resolution level is improved.

Thus, models must be validated in accordance with the **space** and **time dimensions** of the samplings used to produce the basic **data**. There is always a danger of unwarranted interpolations or extrapolations, be it in **discrete (digital)** or **continuous (analogue)** models.

In any case "...no reality can be defined independently of an organization level" (R. PASET, 2000, P. 49)

→ **Level of resolution**

2862

RESONANCE ^{1) - 2)}

The **reinforcement** of a complex **effect** by the periodic coincidence of the different **periods** of the composing motions.

I. STEWART explains this as follows: "The combined motion repeats exactly if and only if the motions are resonant: there is some **period of time** that is an exact whole number multiple of each of the separate **periods**. Usually this doesn't happen" (1989, p.45).

When the respective **periods** are expressed by prime numbers (as for example 19, 91, 103 and 283) the exact whole number multiple becomes very great and the global periodic coincidence becomes practically unobservable, which does not necessarily mean that it does not exist.

I. PRIGOGINE states: "Resonance corresponds to the points where the ratio of **frequencies** is a rational number. Non-resonant points are points where this ratio is irrational" (1989, p.483).

Resonance may thus manifest **deterministic chaos** by combination of various movements of incommensurable **periods**.

As an example, resonance between asteroids and planets orbits may lead to orbital **instability** when the **configuration** brings the smaller body very close to the bigger one. This is for example the explanation of the perturbing influence of JUPITER on many asteroids and comets (C. MURRAY, 1989, p.61).

A dramatic example has been the destruction of the formerly periodic Levy-Shoemaker 9 comet in 1994, when swallowed by Jupiter.

According to E. JANTSCH resonance is as well basic in mental **phenomena**: "Between two static forms no exchange of **information** is possible in free **interaction**, but between two **metabolic** forms free **interaction** can have large qualitative effects. The topological product of two structurally stable systems is generally not structurally stable: the likely degeneration to a stable **field** leads to resonance" (1975, p.42).

In his study on the "Attentive Brain" S. GROSSBERG proposes a computational approach to resonance, based on the study of a **neural network**: "Adaptive Resonance Theory". He states: "In an ART **neural network**, **information** can flow from **short-term** to **long-term memory** during **learning** or from **long-term** to **short-term memory** during **recall**" (1995, p.440).

This may be the key for explaining the (more or less) **markovian** or **chaotic interrelations** between **short-** and **long-term processes** in general: **long-term** is constructed as an accumulative synthesis from **short-term** movements, but **short-term**, in the long run is submitted to **long-term limits**, representative of more general and permanent conditions.

2863

RESONANCE (Inductive) ²⁾

The synchronization of slightly out-of-step **oscillators** under mutual influence.

This curious effect was discovered by HUYGHENS in the 17th century (the spontaneous **synchronization** of two slightly out of phase clocks when fixed to a thin wooden board)

Inductive resonance is far from being limited to mechanical **oscillators**. As noted by LASZLO, it is related to "... the question of the **stabilization** around dynamically stable integral **configurations** in **complex systems**" (1974, p.217).

"It is found to occur in the **energy** transfer in photosynthesis between chlorophyll *a* and *b*, in the **synchronization** of the flashes of the fireflies, in the action of electronic pacemakers on the heart, in the adjustment of alphasrhythms to stroboscopic flashes perceived through the eye" (ibid).

2864

RESONANCE (STOCHASTIC)

→ **Stochastic resonance**

2865

RESOURCE MANAGEMENT ^{1) - 4)}

C. HOLLING states: "The **resilience** and **stability** viewpoints of the **behavior** of **ecosystems** can yield very different approaches to the management of resources. The **stability** view emphasizes the **equilibrium**, the maintenance of a predictable world, and the harvesting of nature's excess **production** with as little **fluctuation** as possible. The **resilience** view emphasizes **domains of attraction** and the need for persistence" (1976, p.87).

There is however a serious **criteria** problem with the definition of "nature's excess **production**". It is coming evermore obvious that our **lineal** view of natural systems is flawed and that our appreciation of global ecological **stability** is therefore quite dubious (when it exists !). As a result: "The very approach... that assures a stable maximum sustained **yield** of a renewable resource might so change these deterministic conditions that the **resilience** is lost or reduced, so that a **chance** and rare **event** that previously could be absorbed can trigger a sudden dramatic **change** and loss of the structural integrity of the system" (ibid).

Consequently, HOLLING proposes two complementary **strategies** for resources management: "The first would lead to the **design** of highly optimal systems in which **fluctuations** were minimized and explicit efforts were made to minimize the probability of failure – in short, a **fail-safe strategy**. There is absolutely nothing wrong with that if, accompanying that **strategy**, is an explicit ability to maintain a **stability region** of a **size** large enough to contain any unexpected **perturbation** the system might receive" (p.89-90).

However the unexpected is, by its nature, very difficult to define and predict. Moreover, human systems tend generally to maximize **growth** and resist any **regulation** until slowed down, blocked or even destroyed by the consequences of its own abuse, as shown by numerous historic examples.

In HOLLING's opinion, it is "almost inevitable that an attempt to reduce **fluctuations** would, at the same time, cause a shrinkage of the **stability** region through the action of cultural or natural **selection**" (ibid).

As a solution, HOLLING proposes a **safe-fail strategy**, that should "... optimizes a **cost** of failure and even assures that there are **periodic** "minifailures" to prevent evolution of **inflexibility**" (ibid).

As an example, let us capture periodically a lesser number of whales, in order to have still whales around in a more or less distant future... Or suffer frequent small tremors in order to avoid the great destructive earthquake.

→ "**Power laws**".

2866

RESOURCES¹⁾

Any type of **matter**, **energy** or **information** that the system may obtain from its **environment**.

Resources should not be confounded with **reserves**, which are resources already obtained by the system and stored within it for future use.

Environmental resources are not illimited, even if at times they seem to be. It is important for the systems which depend from them for their **survival**, to use them at a **sustainable rate**.

The competitive struggle for resources is a frequent occurrence and may be dangerous for the **survival** of some interested system.

In many cases however, such a struggle leads to the appearance of a **regulator**, which usually uses for itself a small part of the resources. This arrangement, once accepted or imposed, generally produces a settlement, favourable for all the participants.

A high **variety** of resources in an **environment** leads to much diversity of the systems that exploit them.

2867

RESPONSABILITY

→ **Rights and Responsibilities (Bill of)**

2868

RESPONSABILITY in systemic terms⁴⁾

Responsability makes sense only in **human systems**, i.e. for individuals in their multiple social **roles**.

However the systemic **approach** vastly modifies and amplifies the scope of the concept, as it modifies and amplifies our worldview. An example is the sense of ecological **responsability** which is starting to pervade ever vaster social **groups** and individuals. This is a result of our recent **awareness** of our growing power to impair **ecosystems** at any **level** through our careless or abusive **activities**... and to find ourselves victims of our own irresponsible **behavior**.

Another example is our new understanding of the ways so many **issues** and **situations** are becoming evermore complex due to growing and accelerating short and long distance **interactions** resulting from our enhanced means of action and long **distance** transport and **communication** capabilities.

At the same time the scope of our multiplied potential responsibilities is becoming more and more wide-ranging, it also becomes more diffuse. Most people remain unaware of many consequences of their activities, mainly because these do not become immediately and widely perceptible. Other people chose to ignore some of their responsibilities for personal interest reasons and in the belief that that will be able to escape scrutiny and punishment

of abuse whose results are not readily obvious (the so-called "tragedy of the **commons**"), or whose victims are unable to defend themselves.

What still generally lacks in our new situation is the **time dimension**. We have lost much of the trans-generational sense of responsibility proper to many archaic and traditional societies. Until now, the **long-term** view has generally not entered individual mentalities and the **evolutive acceleration** in our human systems **transformations** could easily overwhelm us.

True sense of responsibility must now also become systemic, in **space** and **time**. Already in 1979, Sir G. VICKERS, an outstanding systemist and former President of the ISSS, wrote: "Statements of human rights must be replaced by statements of human responsibility if we are to make the world viable" (1979, p.371)... Let us say, if not replaced, at least complemented with!

The most general nature and extension of human responsibility in individual and collective terms has been deeply researched recently by T. ECIMOVIC, M. MULEJ and collaborators, in their work " systems thinking and climate change", published at the University of Maribor, Slovenia (2002)

It could be said that personal responsibility must now include not only ethical one, but also a deeper and wider understanding of the general issues at stake.

→ **Right and Responsibilities (Bill of)**

2869

RESPONSE of a system¹⁾

"... a system **event** for which another **event** that occurs to the same system or to its **environment** is necessary but not sufficient" (R.L. ACKOFF, 1972).

ACKOFF states: "Thus a response is an **event** of which the system itself is a coproducer". He gives an example in order to distinguish a response from a simple **reaction**: "... a person's turning on a light when it gets dark is a response to darkness, but the light's going on when the switch is turned: a **reaction**" (Ibid).

2870

RETENTION

→ **Hippocampus; Object-in-time**

2871

RETRODICTIVE ILLUSION (The)³⁾

It seems always possible to retrospectively "predict" some **event** that occurred. This implies the *a posteriori* reconstruction of a deterministic chain of successive **events** which led to the most recent one.

The concurrence of multiple causal **events** at the ultimate instant induces the illusion that the **event** had one cause only, that this cause in turn had one cause only, and so on in a ret-

rodictive way. This is of course the result of a **selection** made by the **observer** and goes long to explain many heated debates and even lawsuits centered on "responsibility for..." such or such **situation**.

However true **causality** is complex, as the result of growing interferences between numerous more or less simultaneous or successive local **events**.

The retrodictive illusion leads to the rigorously causal predictive illusion, which, during much time did conceal **deterministic chaos**.

2872

RETRO-PROPAGATION APPROACH²⁾

The calculation of the quickest and most efficient **path** backward, from the **goal** to the actual **configuration** (C. HARDY, 2001, p. 49)

This author writes: "...whenever the final **state** of a system, or the solution to a problem, is known in advance, but the intermediate steps remain unknown, it is appropriate to use a **procedure** in which current **events** are guided by future outcomes" (Ibid)

Future planified outcomes install in fact a **feedforward**.

Hardy adds: "Some **neural nets**, for example, operate by retro-**propagation**, comparing, at each step, the current state with the final one, looking for the shortest route from the desired final state to the current one" (Ibid)

The retro-propagation approach leads to impressive success in chess-playing by computer.

→ **Epigenesis; Parallel distributed processing**

2873

REVALIDATION (Cybernetic cycle of)¹⁾²⁾

In his well known lecture "The surrogate world we manage", St. BEER explained why and how our **model** of any factual **situation** or **issue** must be constantly (or at least frequently) revalidated (1973)

Modeling should be ideally a dynamic ongoing **process**, at least for five reasons:

1- our **perceptions** of anything in the world outside ourselves (and even inside!) are always partialized, as our senses are such imperfect perceptive devices (even when aided by instruments)

2- our model construction is subjective by nature and depends on our acquired **frames of references** and their more or less frequently verified relative validity

3- we tend to confuse our model with the **objective/reality** (as we understand it)

4- after a **time lapse**- that can be long or short- the external situation has probably changed, and sometimes very much so

5- when we make **decisions** for **action**, apply them to the perceived issue or situation and the results are unsatisfactory, we tend to cling

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

to our model, whatever the **cost**, and thus introduce our own **evaluation** problem as one more factor of **disturbance**

Consequently we should revise and recycle our models in a cybernetic way, considering registered external **changes** and the results of our own interventions as recurrent **feedbacks**
→ **Decision making; Program; Strategy**

2874

REVERSIBILITY ^{1) - 3)}

The character of a **process** whose direction of **change** can be reversed by a suitable alteration, *however small*, of the (generalized) force applied to produce the **change**. (Adapted from A. LOTKA, 1956, p.23)

Reversibility is a purely abstract concept. The direction of **change** can be reversed... but only through an irreversible movement from a former to a later **state**.

In real **processes**, any **action** causes some **dissipation of energy**, *however small*, i.e. "its conversion into heat at the temperature of the surroundings" (Ibid). Thus the **2d law of thermodynamics** is the impassable barrier against reversibility, as stated for instance by F. HEYLIGHEN: "Reversibility is equivalent to the non-increase of **entropy** (i.e. the non-decrease of **information**)" (1989, p.369).

Moreover, any **process of change**, even a reversal one, supposes a **lag in time**, which also is in accordance with the **2d law**.

2875

REWARD ¹⁾

A positive return obtained by a system through some adequate **action**.

The search for reward necessarily implies **relevance criteria** about what should be defined as a reward. Such **criteria** would be based on results of former experiences (not necessarily always a perfect source of **decision-making**).

According to G. PASK there is "a basic **distinction** between reward, as used in **computer programme** to mean that a rewarded **event** becomes more probable, and reward as it used in a system able to create fresh **components** and **parts** of itself. In this latter case, reward means ability to develop, ability to expand, and ability to become **stable** by becoming a larger system" (Quoted by P. CARIANI, 1993, p.25).

In any case, in the definition, "adequate" sounds somewhat tautological... and anthropomorphic. Moreover, many human systems seek "positive" rewards, and obtain them. But there is generally no guaranty that **short term** rewards would not exact some unknown back pay later on.

2876

REWARD LOOP ²⁾

A **positive feedback** emitted by a downstream system which favors an upstream system from which it thus gains an increase of useful **inputs**.

H.T. ODUM explains this in the following terms: "In ecological studies there is the **positive feedback loop** through which a downstream recipient of potential **energy** rewards its **source** by passing necessary materials back to it. For example, the animals in a balanced system feed back to the plants in reward loops the phosphate, nitrates, and other compounds required for their **growth**... Species whose work efforts are not reinforced are shortly eliminated, for they run out of either raw materials or **energy**. They must be connected to **input** and **output flows** to survive" (1971, p.150)

Reward loops act as **selectors**. This conceptual frame, as noted by ODUM, can be readily applied to economics, where "... money provides a means for organizing **energy flows**" (p.174-177). As suggested by K. BOULDING, "**ecosystem**" seems an equally suitable name for ecological and economic systems... and even possibly for their unavoidable **integration**.

2877

REWRITING ²⁾

An **algorithmic process** based on a **recursive rule** for the application of some of its **rules**.

Rewriting in **algorithms** tends to produce repetitive and **self-similar forms**, frequently in **fractal form**. The rewriting conditions can be differentially adapted in order to create more realistic **models** of natural **forms**.

→ **Growth algorithm**

2878

RHEOMODE ³⁾

A mode of thinking and of using **language** that underscores a world view in which "... all is an unbroken and undivided movement and ... each "thing" is abstracted only as a relatively invariant side or aspect of this movement" (D. BOHM, 1980, p.47)

D. BOHM, who proposed this neologism, states that this new mode "... can help to draw our attention to the way in which our ordinary **language-structure** puts strong and subtle pressures on us to hold a fragmentary world view" (Ibid).

BOHM observes that our present **language-structure** is "... dominated by the divisive form of **subject-verb-object**... (which) tends continually to lead to fragmentation" (Ibid, p.31).

As we are generally not conscious of this ingrained bias, our whole way of forming concepts and models becomes unilaterally distorted.

BOHM does not give many factual indications for acquiring the art of such rheomodal **language**, but A. KORZYBSKI, in "Science and Sanity" offered numerous psychological tricks to practice it (under the different label of **non-aristotelician language**) (1933, 1950).

2879

RHYTHM ^{1) - 2)}

A **pattern** of movement, characterized by the **recurrence** at a regular **frequency** of some pulse in a **process** or system.

Rhythms are ebbs and rises in periodic **phenomena**.

They are generally a **synchronic response** (in **phase** or out of **phase**) to some other rhythm at a more embracing **level**. They can be simple or complex and are observable on the whole scale of **phenomena**, from nuclear physics to cosmic ones. They are also present in ecology, economy and in social **evolution**.

They should thus be considered as a general family of **isomorphic** features in systems.

Rhythms are present, for instance, in climates (and all biological and economic activities under their dependence: for ex. **circadian rhythms**), in oceanic tides, in light and sound and generally electromagnetic waves; in **populations ecology**; in physiological activities (from heartbeats to vegetal **growth**) and quite possibly in **history**.

C.A. BOGDANSKI has produced an interesting list of correspondences between physical or biochemical rhythms and physiological ones (1969, p.113).

There is a great **variety** of rhythms, corresponding to **oscillations** of **short, medium** and **long periods** or **frequencies**; and also to specific systemic and **subsystemic processes**.

2880

RHYTHM (Circadian)→ **Circadian Rhythm**

2881

RIGHTS and RESPONSABILITIES (Bill of) ⁴⁾

G. and E. PINCHOT proposed a "Bill of Right and Responsibilities of the Intelligent **Organization**" (1993, p.364-5) in which every right is balanced with a corresponding responsibility. For example, freedom of **inquiry**, as a basic condition for freedom of **learning**, is balanced by the responsibility to be "curious, persistent and aware"; or freedom of **association** is balanced by the responsibility to "make commitments wisely"; or freedom of speech is paired with the responsibility to "tell the **truth**, the whole truth and nothing but the truth".

All this amounts to the establishment of better psychosocial **regulations** in **human systems**, as so many people are – or feign to be – unaware of the impossibility to maintain systems which would produce only **outputs**.

G. DYER is now spreading this "Bill of Rights and Responsibilities" for orientation of the general **behavior** of people within the **groups, organizations and societies** in which they participate, and most specially in **design groups** (1996, p.52-53).

He has described a number of complementary **behaviors** such as the right of one individual is guaranteed by his/her the admission of a complementary responsibility from his/her part. Here are some examples:

The right to "freedom to communicate one's views without fear" must be balanced by the responsibility to "not dominate **conversation time**". Or the "right to take individual **decisions**" should be complemented by "recognizing the possible consequences of individual **decisions** and face them up if required".

The proposal amounts to the introduction in human affairs of psycho-social **regulations rooted within the individuals** and should lead to better equilibrated, more productive and less damaging activities in any human group.

It amounts thus to a practical psycho-cybernetic device.

2882

RIGIDITY¹⁾

State of a system whose **stability** may be endangered by even small **changes**.

While an excess of rigidity is dangerous, a minimum of it is nevertheless necessary in order to maintain the systems **coherence**.

Rigidity in systems increases generally with **time**. It is expressed by a progressive decrease of the ability to fluctuate between the **limits of stability** and, quite frequently, by a shrinking of these **limits**. One may also interpret it as a decrease of **variety**, in the sense given to it by ASHBY, obviously going with a lessened capacity to adapt to the **variations** in **environments**.

2883

RING

→ **Connection modes**

2884

RISK ANALYSIS¹⁾

That part of the **decision process** that tries to evaluate the probabilities of negative outcomes of possible alternative courses to be taken.

Risk analysis is as necessary as it is difficult. Any **decision** introduces new conditions that modify the global **situation** in ways difficult to forecast.

Possible systemic tools for risk analysis are **scenarios**, complex **cyclical models**, **systems dynamics**, and even **chaos theory**. None however can give any absolute certainty.

2885

RISK MAKERS¹⁾⁴⁾

"**Decision** makers whose **decisions** make risk for others, but not necessarily for themselves" (M.H. GLANTZ, p.12)

GLANTZ applies the concept to the case of the Moscow bureaucrats who took the **decisions** that led to the drying of most of the Aral Sea.

He adds: "The bottom line is that risk makers are often not held accountable for the **environmental crises** that result from their **decisions**" (Ibid).

Two more aspects should be emphasized:

1. Leaving apart the (frequent) case of risk makers who quite consciously take **decisions** in benefit of some pressure **group**, many are basically victims of their ignorance of **synergic effects**. Such ignorance generally results of their narrow specialized angle and incapacity of appreciating **cross impacts** with other **issues**.

2. Risk makers are also indifferent to the possible **long-term effects** of their **decisions**, and ignorant of any sound **prospective methodology**.

In any case, paraphrasing Lord KEYNES, in the long run, we will all be dead. This is indeed a powerful incentive to irresponsibility.

2886

RISK SHARING⁴⁾

A collective and cooperative **behavior** in a social group aiming at mutual protection.

The behavior can be observed in many social animals.

Examples are joint heat production or fanning in beehives, reciprocal protection by **swarming** against predators in fish **schools**, or heat sharing by huddling in emperor penguins in the Antarctic.

And it is of course in human **groups** that risk sharing becomes a very general and fundamental behavior in a great variety of ways. P. CORNING considers sharing activities of all kinds as a typical **emergence phenomenon** produced and expressed through **synergies** which are in his view a "pan-disciplinary phenomenon" (1998a and b)

→ **Herd effects**

2887

RISK (SYSTEMIC) in human issues⁴⁾

The possible appearance of **states** in which the individuals rational or irrational **reactions** to the risk as it is perceived, increases the **instability** of the system instead of reducing it.

This happens for example in markets and leads to panics and crashes. This **phenomenon** is related to **runaway processes** wherein **positive feedbacks** lead to explosions or **collapses**.

2888

RITUAL⁴⁾

A spontaneous **mechanism** of social **control** characterized by non-rational **behavior** uncritically adopted by the members of the **society**.

A ritual is a behavioral **template**, obviously of evolutive origin. It operates a socially and transgenerational **recursive** pre-conditioned conditioning based on a **set** of mostly gestual **communication devices** (in fact a **language** in a very general sense). It is **representational** and tends to standardize **learning** and use of basic **behaviors**.

Rituals seem to have their roots in some animal **behavior** like nuptial parades, territory marking and danger signalling. In human societies, they become masses manifestations, generally religious or ideological. They strongly inhibit individual **behavior** and, by reinforcing adhesion to common beliefs, **values** and **norms**, focalizes mass **action**. Consequences can be either positive, or negative.

→ **Consensus; Culture; Imitation; Meme; Memetics; Schema**

2889

ROBOT¹⁾

A **machine** or device that works automatically or by remote **control**.

The term is originally czech and derives from the slavonic root that means "work"

The humanoid robot is mostly a science-fiction fantasy. However **robotics** is an increasingly diversified research subject with industrial applications and wide theoretical extensions.

2890

ROBOT (KHEPERA)¹⁾²⁾⁵⁾

A robot constructed at the Lausanne Federal Polytechnic School by D. Floreano and his team (2002, p. 24-28) (2002-03, p. 40-52)

This robot is adaptable, i.e. able to modify its **behavior** according to its **perceptions**

It is now used to study what the FLOREANO team calls "**artificial evolution**".

This team is also researching the "predator-prey" **interactions** using two robots, whose behavior is evolving and becoming more and more complex.

These studies are also renewing the **co-evolution models**.

→ **Animat; Artificial Life; Fitness function; Neural networks; Parallel distributed processing; Weights (Synaptic)**

2891

ROBOTICS⁵⁾

The science that studies electronically commanded devices (called robots) able to autonomously perform tasks, and the techniques that allow to construct such devices.

¹⁾general information²⁾methodology or model³⁾epistemology, ontology and semantics⁴⁾human sciences⁵⁾discipline oriented

In a more abstract way, it has been defined as "the intelligent **interconnection** between **perception** and **action**" (E. BUCHBERGER, 1987, p.70). This author states: "Robotics is concerned by all aspects of construction and use of robots, as for example **regulation** techniques, sensorics, tasks **planning** and **knowledge representation**" (Ibid).

The term "robot" comes from the Czech "robota", meaning heavy labor and was introduced by the Czech novelist K. CAPEK.

Two widespread tendencies- one informal, the other formal- have influenced, and possibly hindered, the advance of robotics. The informal one is the popular interest in humanoid robots, which derives from a historically quite old mechanistic **model** of **automata** (VAUCANSON's duck, the "turkish" chess player...and even Dr. Frankenstein's wretched creature)

The formal model has been transposed from computer programmed **artificial intelligence**.

As to the old Jewish Golem, it is neither a **mechanism**, nor a computer ghost. In fact, it is the actor of a significant philosophical story, even if it nourishes popular fantasy.

Robotics has now escaped from these dead ends. It is however still too early to know where so-called **artificial life**, as a **bottom up self-organizing** range of interacting **rules** and **processes** could lead us.

→ **Algorithm; Heuristics; Perceptron**

2892

ROBOTICS (Evolutionary) ¹⁾⁵⁾

The study of individual **adaptation** and species **evolution** through the **observation** of **robots** equipped with so-called **neural networks** made of interconnected electronic **components** able to modify their **interrelations** and **global behavior**

2893

ROBOTS (Social) ^{4) - 5)}

Groups of **artificial organisms** able to develop a coordinated **behavior**.

Such **groups** are showing what is now called **swarm intelligence**, as can be observed in ants or bees... and **human societies**.

Various **Artificial Intelligence** laboratories in the world are presently experimenting with **self-organizing groups** of robots: at M.I.T. (R. BROOKS and P. MAES), at Brussels Free University (L. STEELS), at ONERA and Paris VI University (J. ERCEAU and J. FERBER).

This research in so-called "**artificial life**" is at least partly inspired in insect societies. It seems promised to a considerable technical future (for example in extra-terrestrial exploration). It is however probably even more important in relation to our **knowledge** of the general systemic nature of **sociality**.

As an example L. STEELS, quoted by S. LEVY (1992, p.302), constructed "a robot **ecology**" based on functional **self-organization**... drawing from the social insects and **cellular automata** studies of his neighbors at the University of Brussels, studying under PRIGOGINE, and postulating robots running under BROOKS's **subsumption** architecture".

The subject is also related to **emergence** through **dissipative structuration processes** affecting, in this case, groups of numerous interacting **elements**. (See for instance P.M. ALLEN, 1980 and 1982).

2894

ROBUSTNESS ¹⁾²⁾

Generally, the quality of a device- or by extension, a system; **network** or **automaton** able to resist even important **disturbances**, or the loss of some **elements**.

Robustness is obtained mainly in two ways:

- 1- by the presence of a number of duplicate elements which can replace the disabled ones
- 2- by the high **variety** of the possible **couplings** between two, or more elements

A frequent condition for robustness is the existence of **redundancy** in the system

→ **Automata (Reliability of); Automata network; Hologram; Network; Redundancy in networks; Reliability**

2895

ROLE ⁴⁾

The specific **behavioral repertory** of differentiated individuals in a **social system**.

Roles are constructed through **conditioning**, **training** and **learning** within the individuals. This **process** is transgenerational and is needed to maintain the continuity through **time** of the **social system (time-binding)**.

Any society needs a variety of different roles in order to fulfill the various **functions** needed for its **survival**. In very complex **human systems**, roles become evermore differentiated.

Any individual or **element** has generally a **variety** of roles in her/his/its society or system, each one related to some specific **situation** or circumstances. As observed by F.K. BERRIEN, "role **behavior**" (**output**), is generally "a **response** to the role expectations by others (their **outputs** serving as **inputs** to the behavior)" (1968, p.106).

Roles can be modified even in insect societies (see: **Sociotomy**). In **human systems**, the **repertory** itself, that corresponds with a specific role, can be modified in an adaptive way. Moreover, any individual adopts normally a succession of different roles during her/his/its lifetime.

2896

ROOT DEFINITION ¹⁾²⁾

"A concise, tightly constructed **description** of a **human activity system** which states what the system is" (R. RODRIGUEZ ULLOA, 1999)

"What it does is then elaborated in a conceptual **model** which is built on the basis of the definition. Every **element** in the definition must be reflected in the **model** derived from it. A well formulated root definition will make explicit each of the **CATWOE elements**. A completely general root definition embodying **CATWOE** might take the following form:

"A (...O...)-owned system which, under the following environmental **constraints** which it takes as given (...E...) transforms this **input** (...) into that **output** (...) by means of the following major **activities**, among others: (...), the **transformation** being carried out by these **actors**: (...A...) and directly affecting the following beneficiaries and/or victims (...C...). The world-image which makes this **transformation** meaningful contains at least the following **elements** among others: (...W...)"

"A root definition describes a notional system chosen for its **relevance** to what the investigator and/or the people in the problem **situation** perceive as matters of contention" (Ibid).

2897

ROUTINE ²⁾

A fixed **set** of instructions in a **program**, that can be used everytime in similar **situations**.

H. SIMON explains: "Any **module** (or routine) in a well structured **program**, can be characterized by the **inputs** it needs, the **outputs** it produces and the **transformations** it operates on the **inputs**. The internal **language** used in such a **module**, its way to operate the **transformations** are not significant for its characterization. Thus any other **module** in the system may call on a given **module** without any need to know its internal **structure**; the whole **communication** between **modules** is channeled through their **inputs-outputs**" (1990, p.141 - retranslated from French!).

It seems thus that routines are necessarily **algorithmic**.

2898

ROUTINES (Ecology of) ^{2) - 4)}

The relations among "various procedures (that) mutually support each other and form a more or less coherent **pattern** of "standard operating procedures" (A. HAUAN et al., 1992, p.1061).

According to A. HAUAN, J.A. JOHANNESSEN and J. OLAISEN, who introduced the concept: "The overall functioning of an **organization**... is to a large extent dependent on the qualities of the collective-level routines".

As various participants are bearers of different routines, the authors add: "**Heterogeneous groups** are preferred to **homogeneous groups**, to enhance **complementarity** and avoid standardisation, fragmentation and segmenting of **patterns** of thought and **behavior**".

The concept seems to be an application to social **organization** of BATESON's ideas.

2899

r-STRATEGY²⁾

A strategy resorting to the use of "a large number of low **energy organisms** whose short **life span** is compensated for by a very high rate of reproduction" (R.N. ADAMS, 1988, p.134).

This strategy, based on quick replacement, is opposite to the K-strategy. It is convenient in turbulent conditions, with a high rate of **disturbances**.

According to ADAMS: "Nonhierarchical organizations are more like the r-strategy". Moreover: "r-type **organizations** can fragment and still retain their capacity to survive in refugee areas" (ibid).

The concept has been applied in ecology by R. MARGALEF and seems significant for, at least, small **human systems**.

2900

RULE^{1) - 2)}

"A set of **constraints** which are local, arbitrary, **structure**-dependent, and associated with **rate**-independent aspects of **control**" (T.F.H. ALLEN & T.B. STARR, 1982, p.276).

A fine example are the rules of chess.

H. PATTEE (quoted by ALLEN & STARR, p.42) writes: "The basic **distinction** between **laws** (Note: i.e. so-called "Laws of nature") and rules can be made by these **criteria**: **laws** are a) inexorable, b) incorporeal, and c) universal; rules are a) arbitrary, b) **structure** dependent, c) local. In other words, we can never alter or evade **laws** of nature, we can always evade and change rules. **Laws** of nature do not need embodiments of **structure** to execute them; rules must have a real physical **structure** or **constraint** if they are to be executed" (PATTEE, 1978). In this sense, legal codes are in fact systems of **rules**.

PATTEE's concept of laws is quite platonian: we can discover them only by seeking common features to a number of rules relatives to "real physical **structures** or **constraints**" proper to **concrete systems**.

One could say either that the laws are immanent in systems, or results from their pre-organized "reading" by the **observer**. In this way K. KRIPPENDORFF states: "The search for rules rather than laws distinguishes two schools in **communication** research, the **cybernetics** of observing systems from the **cybernetics** of observed systems and perhaps the social sciences from the natural sciences" (1986, p.67).

J. CASTI, possibly wandering on the border between laws and rules, writes: "Scientific rules are **objective** in that they are relatively free of investigator bias... For example, the exponent in NEWTON's inverse square law of gravitation is 2 and not 2,315 of 17 or any other number besides 2... In short, the rule is **observer-invariant**" (1994, p.13). While this is somehow contradictory with the definition and PATTEE's opinion, it softens somewhat **ontological skepticism** and is a counter-weight to a tendency to **solipsism** that seems sometimes to threaten **autopoietic** approaches.

Rules are *generative*, i.e. they **constrain** the **set** of possible combinations of **elements** in a specific way.

Rules are either introduced through a **program**, or indirectly constructed in an automatic way.

2901

RULE DISCOVERY²⁾

"The replacement of rules of low strength by new rules when environmental **situations** are ill-handled" (J. HOLLAND, 1992 p.176)

This **process** is proper to evolving adaptive **rules-based systems**. It uses **recombination**.

It leads to "generating plausible replacements for rules assigned low strength" (ibid, p.179), through a credit assignment **algorithm**, and is the motor of **adaptation** in systems of this type.

→ **Back propagation algorithm; Evaluator; Pattern recognition**.

2902

RULE (If - then)²⁾

Any rule that establishes the conditions of a specific **behavior**, or various alternative ones.

M. BODEN states: "A rule may include several conditions in its IF-side and several **actions** in its Then-side" (1990, p.215). Commenting on an abstract drawing program (AARON), she states: "Abstract-AARON's If-Then rules may be fairly complex. Several aspects (not just one) of the current state of the drawing may have to be checked, before the **program** knows what to do next" (p.143).

If - then rules are used in what A.I. workers call "production systems", notably **expert systems**. BODEN gives the example of an **expert system** for the detection of soybeans diseases, which includes an array of descriptors of various types: environmental ones; global plant ones; conditions of leafs, of stems, of fruit pods, of seeds and of roots. (p.184).

MARUYAMA's **deviation-amplification processes** in **cybernetics** are also based on If-then rules.

2903

RULE (Meta-)²⁾

A rule defining in which way rules should be applied (E. BUCHBERGER, 1987, p.31).

A meta-rule is on a higher **level** of **abstraction** than the rules it controls. Its characteristics depend however of the nature of the *possible interactions* between subordinated rules. This feature is present in any **hierarchically complex system**, as well as in RUSSELL's and WHITEHEAD's **theory of logical types**.

2904

RULE (Recursive)²⁾

A rule applied in a repetitive way, generally in accordance with other rules.

R. SOKAL has shown that recursive rules can generate quite complex **patterns**, particularly when applied in connection with other rules (1968).

Other **models** in which recursive rules are a basic feature are M. MARUYAMA's **deviation-amplification processes** and J. CONWAY's **games of life**.

2905

RULE (Rewrite)^{2) - 5)}

"A rule which apply to a string of characters and replace some of those by another string" (KRIPPENDORFF, 1986, p.66)

The concept comes from CHOMSKY's **linguistics**.

It is however a quite more general feature, as being applicable to recoding any stretch in any **code**.

2906

RULE-BOUND HUMAN SYSTEMS⁴⁾

P.A. BALLONOFF enounced a "Theory of Rule-bound Human Systems"(1994, p. 837-860), whose main features are as follows.

Human systems are generally **rule-bound**, because they could not maintain themselves otherwise.

They create their own rules and when these rules stabilize, they become codified (by custom, or law) and turn imperative for the **behavior** of the various social **groups** and their members.

As stated by BALLONOFF, the system has become "rule-bounded" and the rules affect "human **choices** and **actions**".

While the author only alludes sketchily to the fact, in many cases people try to escape from the rules and parallel rules systems appear (as for ex. barter, fraud and smuggling rings, mafia, monopolies). Rule-bound systems may crash if they become inefficient. BALLONOFF shows that rule-boundedness in human systems is prac-

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

tically universal. The French anthropologist C. LEVI-STRAUSS, for ex. described archaic groups which are rule-bound in his "Elementary structures of kinship"(1949)

BALLONOFF exposes in his paper a formal theory of rule-bound human systems, which is useful in order to avoid implicit (or even explicit!) contradictions between rules, specially when transformed into **laws** and **regulations**. This becomes very significant at the constitutional level.

Models of rule-bound systems have practical value for prescriptions of policy, for **anticipation** and **forecasting**.

Moreover specific types of rules apply to specific types of systems. For ex. rules relative to monopolies or oligopolies may be different in small or large economic systems.

Finally BALLONOFF discusses the **evolution** of rule-bound systems in general (p.850-2) and shows that, while for ex. insects societies whose rules are "coded by biochemistry" and are "very, very stable", contemporary human systems rules turn much less permanently settled and , consequently "explicit rules for how to change the rules" are needed.

→ **Evolution; Free-will; Logic and Culture; Operator (Decision; Observation; Pragmatic); Stigmergy**

2907

RULE-obeying transition

→ **Transition (Rule-obeying)**

2908

RULES BASED SYSTEMS^{1) - 2)}

Any system is by necessity of **coherence** somehow rules- based.

However, there are seemingly at least two different kinds of rules-bases. The first type is supposed to determine strictly the **behavior** of the system. In A. PREM's words: "Completeness of rules-based systems means the requirement that there is a rule for each possible **situation** and that the given **set** of rules correctly solves the problem" (1992, p.1344). In such cases the **set** of rules is an pre-constructed and rigorously invariable **algorithm**. This is the general case of **mechanisms** and can be extended with some measure of success only to a limited number of non-mechanical systems as for example chess (as observed by PREM).

Systems based on this **class** of rules have practically no fault **tolerance**: "One single missing, inadequate or damaged rule may stop the whole **inference process**" (ibid. p.1345).

However **connectionism** offers us an alternative: **networks** of rules whose multiple possibilities of **interactions** are so highly **redundant** that the potential combinations are practi-

cally infinite in relation to the probable span of existence of the system. Such **networks** are able to construct specific or specialized **algorithms** to some particular ends without exhausting their capacity to produce new ones. Systems thus equipped are relatively able to adapt themselves to new **contexts** and to learn new **behaviors**.

In W. Mc CULLOCH words a rule of this kind is "... a **message** that could be written many places and read out differently in different **context**" (1974, p.8).

The point is also made by St. KAUFFMAN (1993, p.394), who observes that rules can be mutually **triggered** and even "**coevolve** with other rules by mutation, recombination, and **selection**", in biological systems or in **problem-solving computer algorithms**, as stated by J.H. HOLLAND.

2909

RULES (Generative)²⁾

Interacting rules endowed with the potential to develop **complex systems** when applied to some initial group of **elements**.

Such rules, through a prescribed way to combine some type of **elements**, leads to the production of new **elements** and combinations of these elements. The MENDELEIEV periodic table of elements is based on a complex **set** of induced generative rules.

The problem of generating rules has been investigated by various authors, from von NEUMANN and TURING on. M. MARUYAMA studied it in a often quoted article (1963).

The following aspects seem important:

1. Construction rules are framing **algorithms**, whose potentialities are only partially revealed by environmental conditions: in another **environment** they could produce a different **structure**.
2. The original **order** of the **elements** exerts a determining influence on the way the rules will act. They have a **positional value** and, in real systems, specific characteristics, as for example in the case of genes.
3. In MARUYAMA's words: "When the rules are unknown, the amount of **information** needed to discover the rules is much greater than the amount of **information** needed to describe them" (p.168). This is another way to express that the **set** of rules constitutes an **algorithm**.

Generative rules, when complex and not over-constraining, can produce a practically infinite **variety**, as for example genetic **codes**, chess rules or, in music, classical harmony as well as dodecaphonic rules. (M. BODEN, 1990, p.38-40).

2910

RUNAWAY EVENT^{1) - 2)}

A giant **fluctuation** in a **composite system**.

Examples of this type of events are catastrophic earthquakes, snow and ice **avalanches**, **population pandemics** or stock market crashes.

Runaway events are unfrequent and quite difficult to predict.

Composite systems are generally **chaotic** and thus **deterministic** only in a very global sense, while subject to **random-like behavior** in time.

In P. BAK and K. CHEN terms: "In **chaotic systems** a small initial **uncertainty** grows exponentially with **time**. Furthermore, as one attempts to make **predictions**, further and further in the future, the amount of **information** one needs to gather about the **initial conditions** increases exponentially. For the most part, this exponential **growth** prevents **long-term predictions**"(1991, p.32).

A runaway event generally leads to a **catastrophe discontinuity**.

→ **Power laws**

2911

RUNAWAY PROCESS^{1) - 2)}

An irreversible **processs** through which a system is forced through an **instability threshold**.

Such a process implies the swift loss of **dynamic stability** and may lead either to the destruction of the system (f. ex. **growth** of a cancer), or to **dissipative structuration** and **emergence** of a higher **level of complexity**.

A runaway results from the **action** of an uncontrolled **positive feedback**. J. MILSUM observes: "... upper and lower **constraints** always exist in real systems which prevent true runaway, and may even mask the positive-loop nature of some systems when operating within these **constraints**" (1968, p.39).

As recorded by MILSUM, these **constraints** appear as "floors" and "ceilings" in BOULDING's terminology.

As also noted by MILSUM, **stable** systems avoid runaways by combining positive and negative **loops** (in this encyclopedia: **compensated feedbacks**).

Runaway **processes** are generally destructive, as for example in a fire. They may also lead to **bifurcations**, or "**catastrophes**" in R. THOM's sense, or to a higher **level of stability**, when triggering **dissipative structuration**, as viewed by PRIGOGINE's **thermodynamics**.

The many times used **metaphor** about "**snowball effects**" corresponds to runaway processes.

S

2912

SADDLE²⁾

A general converging point in a three dimensional **chaotic attractor**.

The saddle is formed by two overlapping **fractal structures**, the inset and the outset of an unstable solution.

The central point C of the saddle is common to the stable **manifold** of the system and to its unstable one.

As the saddle implies **convergence**, it is easier to stabilize a **chaotic system** by application of small corrections (or **perturbations**) when the chaotic **trajectory** passes near its central point (D. BROOMHEAD, 1990, p.23).

St. KAUFFMAN writes: "... saddle **steady states** are stable with respect to **perturbations** in some directions, and unstable with respect to **perturbations** in other directions. The existence of saddles reflects the fact that two **stable basins of attraction** must abut, and the ridge where they do is a **basin of attraction** having one fewer dimension than the number of **variables** in the system and is called a **separatrix**" (1993, p.177).

2913

SAINT MATTHEW PRINCIPLE (MARGALEF)^{1) - 2) - 4)}

"For whosoever hath not, from him shall be taken away even that he has" (Matt. 13.12)

(Also known as Saint Mark Principle, 4.25)

This New Testament quote, remembered by R. MARGALEF, has been translated by him in terms of an ecological principle as follows: "When two systems interact, **information** increases relatively more in that one which is already more **complex**, as it seems to feed from the more simple and may assimilate it" (1980, p.28).

Or "The system bigger in terms of acquired **information** is always able to make better use of **information**; that is to say to assimilate and multiply it" (p.27).

MARGALEF considers this principle as "... extraordinarily valuable in **ecology** as well as in **General Theory of Systems**. It could contribute to sharpen the **gradients** of any property that may be interpreted as an **information carrier**" (Ibid).

Indeed, the principle accounts for the progressive evolutive build-up of more **complex systems**, by **integration** of simpler ones: Industrial take-over and absorption of archaic tribes by bigger human groups are examples.

→ SIMON's Hora and Tempus Parable.

2914

SANTA FE INSTITUTE¹⁾

P. BAK writes: "The Santa Fe Institute in New Mexico is a lively center for exchange and debate on **complex systems**...

"The Institute brings together many of the most imaginative thinkers from vastly different fields in an open **environment**. The meetings at Santa Fe are continuous **brain storms**" (1996, p.114)

He adds: "Since the Santa Fe Institute does not have a permanent staff of scientists, it can change its emphasis quickly when new ideas come up. A number of external professors are associated with the Institute... In contrast, traditional university and government laboratory **environments** have a tendency to freeze into permanent **patterns** as their scientists become older. Typically, a couple of long-term visitors, some short-term visitors, and a few young postdoctorate fellows work at the Institute. In addition, scientists from various fields come together at seminars and conferences"...

"These meetings force us to place science in a greater perspective. In our everyday research, we tend to view our own **field** as the center of the world. This view is strengthened by our peer groups, which are, because of the compartmentalization of science, working along the same lines. No mechanism for changing directions exists, so more and more efforts go into more and more esoteric aspects of well-studied areas that once paid off... Nobody has an incentive to step back and ask himself, "Why am I doing this?" In fact, many scientists are put off if you ask this question" (p.115-6)

2915

SANTIAGO THEORY¹⁾³⁾⁴⁾

"A system theory of **cognition**, developed by H. MATURANA and F. VARELA" (F. CAPRA, 1997, p. 174)

Santiago is for Santiago de Chile, as both authors are Chileans.

Santiago theory is practically a synonym for **autopoiesis**.

CAPRA also states: "Mind is not a thing but a **process** - the process of cognition which is identified with the process of life" (Ibid., p. 175)

He resumes the basic ideas of the theory as follows: "In the Santiago theory, cognition is an integral part of the way a living **organism** interacts with its **environment**. It does not react to environmental **stimuli** through a lineal chain of **causes and effects**, but **responds** with structural **changes** in its **nonlinear** organizationally closed **autopoietic network**.

This type of **response** enables the **organism** to continue its **autopoietic organization** and thus to continue living in its environment. In other words, the organism's cognitive **interac-**

tion with its environment is intelligent interaction... manifest in the richness and **flexibility** of the **organism's structural coupling**" (1991, p.269)

The basic importance for **cognition** of the **interactions** of the living **organism** with its **environment** was already clearly sensed by J.von UEXKULL in his theoretic biology and **ethology** research (1928, 1934) and, in a different way by A. KORZYBSKI in his work about the relations between our **perceptions** and the way we construct our **abstractions**, as well as about our very semantically based **reactions** to our perceptions (1950)

→ Semantics; Structural differential

2916

SATISFACTION PRINCIPLE^{1) - 2)}

"When affected by undesirable **disturbance** the **organism** changes **control** so that the (vital) performance indicators (**variables**) stay within the **satisfaction range** as long as the **disturbances** stay within **uncertainty sets**. Furthermore, any **control** which accomplishes such a **state** is equally acceptable" (M. MESAROVIC et al., 1973, p.68).

This principle was enunciated by M. MESAROVIC et al in relation to **modeling** of biological **functions**.

It offers a noteworthy similarity with LE CHATELIER Principle, only that its working is more complex, because it implies **regulations of regulations**, by its dependence from a defined **satisfaction range**.

2917

SATISFACTION RANGE^{1) - 2) - 4)}

The range within which some **variables** (in biological systems) "... can fluctuate without seriously affecting the normal functioning of the **organism**" (M. MESAROVIC et al., 1973, p.68).

This notion, introduced by M. MESAROVIC et al., implies a principle of economy as, within the defined range, the system's **regulators** are not uselessly overburdened.

It would be interesting to consider the possible existence of satisfaction ranges in animal and human **social systems**.

2918

SATURATION¹⁾

State of a system that has already absorbed the maximum quantity of **inputs** needed for its correct functioning.

Sub-saturation induces the search of complementary **resources** by the system.

Over-saturation provokes the clogging of the **structures** and the braking, if not the blocking, of the **functions**. It can be observed mainly at the material **level** as in obesity or bureaucratic **multiplication** or, at the **information level** where an excess of **data inputs** overflows the capacity to assimilate and synthesize.

¹⁾general information²⁾methodology or model³⁾epistemology, ontology and semantics⁴⁾human sciences⁵⁾discipline oriented

However energy over-saturation may trigger **structuring dissipative processes**.

2919

SATURATION (Structural)

→ **Structural Saturation**

2920

SCALAR²⁾

A physical quantity expressed by a number on a precisely defined **scale**.

2921

SCALE²⁾

A system of regularly spaced marks used as a **reference** standard for comparative **measurement** purpose.

Scales are generally arithmetic or logarithmic, providing however quite different **representations of dimensions and rhythms in phenomena**.

2922

SCALE- FREE NETWORKS²⁾

A type of network that has many **nodes** (or **hubs**) with few **links** and some few nodes with many links. A.L. BARABASI (2002) has shown that many **communication** systems (whatever the nature of the communication) are scale-free networks. Among them he signals the Internet web, the food webs in **ecosystems** ("who eats whom"), the so-called "invisible college" among scientists (among them systemists and cyberneticians, we should add) and in biology, the complex grid of biochemical products that sustains any living being.

In this very Encyclopedia, a mapping of the cross-references would probably show out as a scale free network.

As a result of their peculiar topology, scale free networks are very resistant to not excessively extended random failures. On the other hand, any propagation of an effect can be modeled by a scale free network. An example is the AIDS pandemics.

Even one single bearer of the HIV can act as a hub in the network, i.e. as an efficient propagation agent in some specific geographic and social conditions. On the contrary, it seems that "cleaning" hubs in internet, could be a useful strategy against viruses.

→ **Hexagonal space filling: Hub; Small world effect; Social system**

2923

SCALE GRADIENT²⁾

"The continuum of **structures** which are seen by an **observer** who continuously **changes** the **size** of his **observation window**" (T.F.H. ALLEN & T.B. STARR, 1982, p.277).

ALLEN and STARR comment: "A disjunction in a scale gradient occurs when very little if any of the substance in the system under investigation is held in **configurations** with **endogenous cycling times** which are simply in tune with the **observation window** in question" (Ibid).

2924

SCALE INVARIANCE²⁾

The permanence of some structural or functional property at different **levels** (say **micro-, macro-, mega-**).

Fractals are scale invariant. WEIERSTRASS' **renormalization** equation is a formalization of scale invariance. See: "**Self-similarity in WEIERSTRASS function**".

D. RUELLE observes that scale invariance in space is related to scale invariance in time (1991, p. 98).

→ "**FEIGENBAUM's number**".

2925

SCALE (Large and small): their relationship^{1) - 2)}

Large and small scale **phenomena** and systems are interrelated **structurally** (in **space**) and **functionally** (in **time**).

Their **structural relations** are obvious, as J. MILLER, for instance, has shown in "Living Systems" (1978): Societies are made from individuals, individuals from **cells** and **cells** from molecules and atoms.

Functionally, **short term phenomena** remain within the frame of **long term** ones: the **waves** within the **tide** and the **tides** within the geological **variations** of seas **level**. (an example that can be also used as a metaphor).

Any **linear extrapolation** from small scale **variations** into **long term** is probably illusory and this explains, for example, many costly **planning errors**.

In most cases, a comprehensive study of embedded **short, medium and long term** movements (and, if more or less regular, of **cycles**) may give important leads for a more realist understanding of ongoing **transformations**.

→ **Cycle**

2926

SCALE (Mesoscopic)²⁾⁴⁾⁵⁾

(From the greek "mesos"= middle)

R. IRION writes: "Objects ranging from a few nanometers to a tenth of a micrometer show special properties that do not occur on **microscopic** or **macroscopic** scales. At this **size threshold**, adding more particles often makes the material not just bigger, but entirely different. Groups of hundreds to thousands of particles -dumb, inanimate **matter**- suddenly be-

gin to organize themselves into **patterns** that make them seem capable of responding to their surroundings"(2001, p. 33)

The mesoscopic scale is shaped through a set of stabilized and repetitive **interactions** that become functional. Another angle on this **phenomenon** is expressed by CSANYI's concept of the "**zero system**" emerging out of an **autogenetic** assembly of precursor **components**

The mesoscopically **self-organizing system** can itself be recognized at different scales. It is obviously active in all cases of self-organizing **human systems**, in **history** and in the present time. (J. WARFIELD, to be published)

M. ROUKES makes the following comment: "At the mesoscale, **matter's** properties result of a combination of classical physical laws and of **quantum mechanics**"(2001)

Many quanta effects are self-compensating, or somehow constrained at large scale. But the trend towards miniaturization and nanotechnology is bringing important techniques (as for example in **computer hardware**) closer and closer to a **critical limit** where quanta effects cannot anymore be ignored. This is now a very basic issue in applied **technology** as related to scale.

2927

SCALE (Ratio)

→ **Logarithmic growth (Semi), Optimum (Dynamic), Ratio scale**

2928

SCALE UNIT²⁾

"The minimum interval in terms of which the scale of the **magnitude** can usefully or definably be graduated".

D. Mc KAY, author of the definition, adds: "For a **magnitude** imprecisely known it is defined... to be equal to the probable **range** of error... But it should be remembered that in theoretical **representations** the **size** of the scale-unit is generally limited by our inability to *define* a smaller unit in terms of the *coincidence-relations* out of which physical **representations** are constructed" (1969, p.168).

Different scale units correspond to different **levels of observation**, and the lesser ones are in a sense embedded into the higher ones. The **understanding** of the various scale units to be used is of utmost importance in the study of complex **cyclical** or **cyclomorphic phenomena**.

2929

SCALE-FREE²⁾

Characteristic of any system whose **structures** and **behavior** are submitted to **power laws** encompassing various orders of **magnitude**.

This property is related to **self-organized criticality**.

In subsystems, the **parts** or **subsystems** have an **organization** similar to the **whole**, i.e. they have a **fractal structure**.

→ **Renormalization; Self similarity**

2930

SCALING²⁾

A **situation** or **process** in which the smaller-scale **structure** or **function** is similar to the larger one.

Sir d'ARCY W. THOMPSON established the notion in his book "On growth and form" (1916).

Scaling furnishes the base for **self-similarity** at different **levels** and is closely related to **fractals**. It has been given a precise mathematical meaning through the **WEIERSTRASS function** and the **renormalization group transformation**.

B. MANDELBROT observes: "Scaling is... an ancient idea, thoroughly familiar to LEIBNIZ; and the scientific application of scaling is the work of many hands" (1982, p.108). He cites Julian HUXLEY's **allometry**; the work of Lewis FRY RICHARDSON in **turbulence** theory and the urbanists' central place theory.

According to J. GLEICK "...**fractal** scaling (is) not just common but universal in **morphogenesis**" (1987, p.110).

It provides a **mode** of **space** occupation allowing for optimum fine structuration at any **level**.

2931

SCALING (LAW of QUARTER POWER)²⁾

This law is stated as follows by R. LEWIN (1999, p.35):

"... many biological **variables** tend to increase or decrease in relation to body mass raised to the power of one quarter or three quarters"

This law "holds true for the smallest micro-organism to the largest animal, the blue whale... a staggering 21 orders of **magnitude**... (and it) remains intact even in the subcellular domain, down to the mitochondria which provide the **cell's energy** and, beyond that to the molecular complexes within the mitochondria... to 27 orders of magnitude" (Ibid)

According to G. WEST, as quoted by LEWIN: "You find scaling everywhere in the **Universe**... as it reflects something of the general properties of the system" (Ibid, p.37)

Scaling is closely related to the nature of **networks** at the various **levels** of **organization** and **energy flows**.

→ **Space syntax**

2932

SCALING PRINCIPLE^{1) - 2)}

B. MANDELBROT distinguishes two different aspects of the scaling principle:

"A. Scaling principle of natural geometry: To assume that small and large features are identical except for scale is often a useful approximation in science.

"B. Scaling principle of mathematical geometry: To limit oneself to **sets** wherein small and large features are identical except for **scale** is often a convenient procedure in geometry.

He adds: "Part of my work consists in viewing B as having provided a collection of answers without questions and in setting them to work on the questions without answers summarized under A.

"The only fairly wide justification for A is that any sum of many **effects** satisfying a "central limit theorem" is scaling. This statement is, of course, too loose to be provable, yet a prudent addition of natural assumptions makes it into provable theorems or plausible conjectures" (1982, p.96).

2933

SCANNING²⁾

Any technique by which recorded **information** can be reviewed for **selection**, use or **transformation**.

Such techniques are basically electronic or optic and are very useful to investigate the internal **organization** of **complex systems**.

A **metaphorical** (but not very proper) extension of the term covers the quick visual and superficial examen of printed material.

2934

SCENARIO 1⁴⁾

A technique in futurology (or **prospective**) consisting in describing a possible future based on existing **data** and selected assumptions.

M. MARUYAMA prescribes the following steps, in accordance with his concepts relative to **interconnected positive and negative causal loops** (see 2nd cybernetics):

"1. Make not one, but several scenarios.

"2. The **purpose** of the scenarios is to consider various possibilities, *not* to make a **prediction**. Therefore they are useful to the extent that they include novel, unusual **elements**. The scenarios made in the past tended to **extrapolate** present **trends** quantitatively. But we need scenarios which include novel qualitative **changes**.

"3. For each causal **diagram**, first put down a novel **element**, such as fertile arid land or outer space industry. Then put down **variables** which are affected by this **element**, as well as **variables** which will affect this **element**. Draw causal arrows with plus or minus signs, strength indicators and **delay** indicators.

"4. Draw causal arrows to and from these **variables** from and to still more **variables**. Repeat the **process**.

"5. Eventually, the diagram becomes too crowded. Eliminate the **variables** which have weak direct or indirect **relations** to the first **element**, as well as the **variables** which have weak effects on the type of business category or the firm for which you are making the future scenario. A workable number of finally selected **variables** is between 10 and 15.

"6. Make a list of all the **loops** found in the diagram.

"7. Eliminate **loops** which have weak **loop** strength or too long a total **time delay**, say 50 years or more.

"8. Now you have a small number of **loops** to consider. Write down in sentences the **dynamics** of these **loops**.

"9. For each scenario, determine whether your firm is a loser or a winner in comparison with your competitors.

"10. Work out a **strategy** to make your firm a winner, and examine its feasibility and obstacles.

"In this type of exercise, you discover that **causal loops** behave in a way very different from what you expect by looking at each causal arrow separately" (1994, p.87).

This way to construct scenarios is satisfactory in systemic and cybernetic terms. It does however still depend on the personal acumen and judgment (or, unfortunately, prejudices and ignorance) of the researcher. The case is quite similar to the construction of the basic **model** in FORRESTER's **systems dynamics**.

2935

SCENARIO 2^{1) - 2)}

A structured behavioral **model** that orients **behavior** in specific circumstances.

The concept has been developed by R.C SCHANK who hypothesizes that we possess "**memory organization packets**", in fact connected stories, gathered from former experiences, which are at our disposal everytime we find ourselves in a **situation** that acts as a **trigger**.

He gives as an example "restaurant **behavior**", as different from "fast-food **behavior**". The **model** has been experimentally confirmed by **computer modelizations**, wherein the **program** stores experiences that can be reused in similar cases (1995, p.151-2).

2936

SCHEMA^{2) - 3)}

1. "A mental **structure** that **codes** and stores external **inputs**, driving the search of the **organisms** for new inputs" (E. PESSA, 1992, p.433).

E. PESSA quotes NEISSER who redefined the concept (1976). He explains that the **structure** is influenced by the **inputs** "when they cannot be coded by using the existing **categories** and a schema modification is required. On the other

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

hand, we have a trend toward self-consistency, because the **organism** is searching only for the **stimuli** that are required by the schema itself" (Ibid).

This is the **autopoietic** aspect of the schema: it tends to **organizational closure**.

This schema concept also seems useful in **organizations**, which apparently react in the same fashion.

Schema construction is more or less equivalent to **back propagation algorithm** shaping.

2. "A **symbolic structure** that can be filled by a specific type of **information**" (E. BUCHBERGER, 1987, p.51).

This is a more formal meaning, in no way contradictory to the former one.

From the viewpoint of **culture**, schemas are social constructions obtained through **consensus**, and transmitted by **imitation** or **education** (H. PLOTKIN, 2000, p.60)

Schemas do undergo a frequent process of **transformation** through **reevaluation** of their soundness, by debate.

2937

SCHEMATA²⁾

"Efficient adaptive plans" (J. HOLLAND, 1992, p. 19).

HOLLAND writes: "Schemata provide a basis for associative combinations of **attributes** with potential for improving current **performance**" (p.68).

He develops the corresponding **methodology** to evolve schemata, that can be used to establish or to describe the best coordination **rules** in adaptive **automata**. (p.66-74)

2938

SCHISMOGENESIS^{1) - 2)}

"Progressive **differentiation**" (G. BATESON, 1973, p.42).

This concept is more or less equivalent to MARUYAMA's **deviation - amplification processes model**. It is also related to **polymorphism** in **populations**, as considered as a factor of **evolution**.

BATESON distinguishes:

- a. symmetrical schismogenesis, where the mutually promoting **actions** of A and B are essentially similar, e.g. in case of **competitions**, rivalry and the like;

- b. complementary schismogenesis, where the mutually promoting actions are essentially dissimilar but mutually appropriate. e.g. in cases of **dominance-submission**, **succouring-dependence**, **exhibitionism-spectatorship** and the like" (p.82).

2939

SCHOLASTICISM¹⁾²⁾³⁾

R. GLANVILLE writes (1999): "One aspect of Scholasticism of great significance was the notion of the **organization of knowledge**.

The scholastic philosophers believed that the way pieces of knowledge fitted together was itself a sort of knowledge. They organized knowledge so that knowing the place of any piece of knowledge in the grand scheme of knowledge (the totality), its **connections** to the **whole**, and, in principle all knowledge- the totality- could be deduced. Every **part** implied (was in concordance with) every other part (each was manifest in the others)"

Glanville quotes PANOFSKY's work on "Gothic architecture and scholasticism"(1957), "arrangement according to a system of homologous **parts** and parts of parts". He adds: "The latin words were *summa*, *concordantia* and *manifestatio*. It is no wonder that the scholastics invented the Encyclopaedia in a form in which we know recognize it"(Ibid)

Today there is obviously a need to compensate- not to eliminate- the massive disjunction between so many specialized disciplines. Systemic and cybernetic **concepts** and **models** should be considered as **semantic** and **linguistic connectors**, that can be used to construct a renovated connected and coherent general **language**, reconstructed in the spirit of scholasticism.

→ **Transdisciplinarity**

2940

SCHOOL¹⁾⁴⁾⁵⁾

A large **group** of fishes or other aquatic animals, swimming in a coordinated way (Synonym: shoal)

By swimming together in large numbers, the members of the school obtain a reciprocal protection because all those who are inside the shoal cannot be easily reached by any predator.

Only the peripheral individuals have incomplete protection. However all members take turns to occupy the exposed **positions**. A somewhat similar **behavior** can be observed in migrating birds (ducks, swallows, for instance)

The school **phenomenon** is obviously a very basic root of **sociality**. It shows the importance of environmental pressure that generates **cohesion**, **coalitions**, **coordination** (and generally what could be called "co-behavior") in groups of originally isolated individuals.

Curiously enough, the school behavior became the **response** of oceanic convoys to submarine attacks during World War II. This behavior was one of the first results of **operation research**

2941

SCIENTIFIC METHOD: A constructivist reappraisal³⁾

The classical concept of scientific method left mental, psychological and **consensual** aspects out of the picture, thus creating the illusion of **objectivity**.

The **constructivist** view explains various formerly puzzling aspects:

- How could we get scientific controversies (some of them quite heated) and "revolutions" (T. KUHN).
- Why and how should scientific theories be falsified (K. POPPER).
- Why did we need a **theory of logical types** (B. RUSSELL - A.N. WHITEHEAD) and why could no scientific - or, for that, logical - explanation be self-validating (K. GÖDEL).

H. MATURANA puts the **constructivist** viewpoint in this way: "As scientists we make scientific pronouncements. These pronouncements become validated through experiments that we make, according to scientific method. This method can be retraced in the following way:

a) *Observation* of a **phenomenon**, *seen* as a problem to be solved;

b) development of a *hypothesis* in the guise of a **deterministic** system able to produce a **phenomenon isomorphic** to the observed **phenomenon**;

c) *generation* of a **situation** or **process** which, in coincidence with the proposed hypothesis, could be *observed* as the **predicted phenomenon**;

d) *observation* of the **predicted phenomenon**" (1982, quoted by P. HEJL, 1985, p.111) (this compiler's italics).

Every italicized term bears a mental or psychological load and, consequently, the results cannot be taken for an absolute **representation** of reality.

Moreover, the construction of so-called scientific **truth** is altogether a matter of **consensus** among scientists, after due debate. And still, such **consensus** is always provisional, until someone challenges it with new **observations** or hypotheses. In this case, the whole **process** must be rehearsed, with unforeseeable results.

2942

SCIENTIFIC REALISM³⁾

In his review of Ch. LANDESMAN's "Introduction to Epistemology", J.van GIGCH writes:

"Scientific realism is a claim about the aims of scientific inquiry. It is a form of **realism** and rejects the various forms of **idealism** and **constructivism** which say that the world we are trying to gain **knowledge** of, does not have an independent and objective existence. It also rejects the **skepticism** which claims that this aim is unrealizable. According to LANDESMAN, "scientific **activity** is a self-correcting activity that is progressive: it gradually provides better and better accounts of the way the world is, and eliminates theories that are epistemically defective"(1999, p. 90)

In fact, these views are very similar to POPPER's.

LANDESMAN adds: "If the success of applied science is no accident, that it is plausible to suppose that our theories capture at least some aspects of reality to some extent" (Ibid)

Of course, even the philosopher most skeptical about reality will not skip his dinner because he cannot be sure it is "real".

→ **Ontological skepticism**

2943

SCLEROSIS^{1) - 4)}

An excessive proliferation of **elements** in a system, that progressively impedes its correct working.

Translated outside biology, sclerosis would seem merely a **metaphor**. However the progressive proliferation of supernumerous **elements** can also be observed in **human social systems**.

F. ROBB writes: "As the institution/**distinction** systems elaborate and expand, so their **efficiency** at doing this should decrease. The **models** which provide meaning should no longer be sufficient to explain **objects**, **events**, and the **processes** encountered in the world. As the institution extends its **boundaries**, there should be a proliferation of **rules** and an increase in the **complexity** of the **classifications** they make. This should increase until the **distinctions** are too complex to convey meaning. The **efficiency** of the institution in making use of the available **energy** should then decline" (1990, p.395).

Sclerosis is probably comparable to ASHBY's too **richly joined** systems, wherein excessive **constraints** reduce **adaptiveness** up to the point of eventually suppress it outright. This leads unavoidably to the demise of the system.

The basic reason for such a **process** is possibly the unending accumulation and **storage** of acquired **adaptations** (many of which will never be used again) and the resulting reduction of the globally limited potential for further **adaptations** in any **autopoietic** system. This may be the conceptual nexus between **ageing** and sclerosis.

It would be of systemic interest to closely investigate the sclerosis **process** in general terms and try to formalize it.

2944

SCRIPT¹⁾

A **semantic description** of a **behavioral pattern**.

According to M. BODEN: "Scripts and **frames** can be thought of as special cases of **semantic nets**. They represent the conceptual skeleton of a familiar idea – such as how one should behave in a restaurant, or what it is to be a room, or a molecule. In other words they are schematic outlines of a tiny part of conceptual **space**. Like **semantic nets** in general, they

can be modelled by **connectionist** systems... Scripts concern socially recognized ways of behaving (involving the **roles** of customer and waiter, for instance)" (1990, p.97).

Current A.I. scripts are thus far more limited than mental scripts.

2945

SEARCH CONFERENCES¹⁾⁴⁾

Search conferences were proposed by F.E. EMERY (1993). M. JACKSON describes them as follows: "(They) emerged from socio-technical systems theory and aim to involve people in the creation of their own future. They promote the development of democratically self-managed **groups** and insist that all those directly involved in a **situation** should participate.

In the case of groups exceeding the recommended fifteen to thirty people for a single search conference, parallel multi-search conferences are organized. They work within organizational and **community contexts** to "rationalize **conflict**", provide a thorough **understanding** of environmental **issues** and **constraints**, and to promote learning" (2000, p. 310)

Fuschl and Asilomar Conversations can be seen in this light, but it should be made clear that they do not include formal presentations and discussion of papers and that the agenda itself is constructed through open and free debate among the participants.

→ **Assumptions; Brainstorming; Codes (Linguistic and semantic); Communication (Human); Consensus; Conversation; Design inquiry; Frame of reference; Language; Observer**

2946

SEARCH (Random)²⁾

A search without pre-instated **rules**.

This is supposed to be the way mutations and natural **selection** do operate.

H. PATTEE observes however: "The first criticism is that random search cannot be expected to 'find' successful **organization** because the search space is so immense. Thus a search for just one sequence of 100 amino acids representing one functional enzyme would require of the order of 20^{100} trials which is not within any reasonable probability within the age or **size** of the universe" (1972, p.38)

H. SIMON proposed his **Hora and Tempus metaphor** about **progress** towards evolutive **complexity** by **hierarchization** as a possible reply to this riddle (1965).

H. PATTEE pursues: "The second criticism is that functional optima or **fitness** peaks in the adaptive landscape appear to be local, separate optima, so that no evolutionary pathway can be imagined that does not pass through nonfunctional or lethal valleys. Random search and **selection** can provide a mechanism for **adapta-**

tion with respect to one of these optima, but for any **fitness** landscape with a realistic number of dimensions, the trapping problem becomes unsolvable" (Ibid).

His conclusion is that we need a mechanism of **self-simplification** to escape from this impossibility. Notably, he considers, like SIMON, that **self-simplification** must be based on **hierarchy**.

2947

SEARCH SPACE²⁾

"The **set** of the **states** through which a problem – solver could conceivably pass in seeking the solution to a **problem**" (M. BODEN, 1990, p.77).

M. BODEN specifies: "In other words, it is the **set** of conceptual locations that could conceivably be visited. "Conceivably" here means "according to the **rules**". Contrary to popular belief, a creative **genre** may be based on precisely specifiable **rules**" (Ibid). M. BODEN gives the example of classical musical composition, based on the **rules** of harmony and observes that dodecaphonic music is also based on a **set** of specific **rules**.

2948

SEGMENTATION^{2) - 4)}

Condition of a system such that each **component** is a structural and functional replicate of every other.

Be it in genetics, in **pattern recognition**, or in **sociosystems**, segmentation takes place according to interacting **rules**.

The concept has been used by L.A. WHITE (1959, p.145-149), who observes that: "The **process** of segmentation is observable everywhere and on all **levels of organization**, physical, biological, and social" and adds: "We now come face to face with a very interesting and apparently fundamental principle: any system, whether it be a segment itself or an **organization** of segments, has a maximum **limit of size**".

WHITE gives a number of physical, chemical and biological examples and concludes: "Thus we observe two aspects of material systems of this sort:

"1. Units tend to combine and form **integrated systems**.

"2. The integrative **process** cannot form larger and larger systems indefinitely; there is a maximum **size** and **limit** for each kind of system" (Ibid, p.146).

WHITE applies this concept to human societies and finds that it is the basic mechanism of **emergence** of more complex **socio-cultural systems**.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

C. FRANÇOIS showed that the **level of complexity** thus attained is related to the the degree of mental and technological development of each human group and that there is an **evolution** toward the **emergence** of ever less numerous, but more complex ones (1993, p.74).

2949

SEGREGATION (Interactive)^{1) - 4)}

The spatial separation of different **groups** through some **code** of reciprocally perceived deterrent or repulsive **signals**.

Interactive segregation has been observed among **populations** of different species of fishes within a common biotope. It results of the production and reciprocal **perception** of biochemical substances by these species (P. SAGLIO, 1992, p.1292). It should be of interest to find out if this mechanism for optimal use of common **resources** through diminishing interferences and infighting does also exist under other forms among other species or **groups**, including human ones.

2950

SEGREGATION (Progressive)^{1) - 4)}

The **process** through which "**components** of a system become increasingly more independent and isolated, leading to the eventual dissolution of the system" (B. BANATHY, 1973, p.88).

According to HALL & FAGEN the concepts of **totality** and **additivity** must be clearly distinguished. By **additivity**, they seem to understand the existence of clearly identifiable parts in the system.

They describe (in a somewhat ambiguous way) two possible modes of progressive segregation in a system.

The first one is related to the **breakdown** of the system: certain **parts** stop functioning and slowly, the functional **interrelations** disappear, up to the point of complete **disaggregation** of the system.

The second one corresponds to **growth** and is somehow antithetical to the first one: "The system changes in the direction of increasing division into **subsystems** and **sub-subsystems** or **differentiation of functions**" (1956, p.22) The authors use as an example the embryo's development or the **differentiation** of a **communication net**.

The difference between both **processes** is so significant that it does not seem quite adequate to use the same expression in both cases. "Progressive segregation" could be restricted to the decomposition **process**. Conversely, structural and functional subdivision, which corresponds to a growing degree of **heterogeneity**, could be called for example, "Progressive **differentiation**".

However, starting from the initial **autogenesis**, progressive **differentiation** and progressive segregation seem to constitute a natural sequence in **complex systems**, in accordance with the **2nd principle of thermodynamics**.

2951

SELECTION¹⁾

Selection is a limiting, negative **agent**, that results in the elimination of some types (biological, economic or social). As observed by W.R. ASHBY, it is equivalent to a "**mapping** that reduces the original **domain** to a **subset**" (1964, p.96). It could however not work without the previous **action** of a creative variegating **agent**, as was already observed in 1921 by A. BOGDANOV in his "Essays in Tektology", where he distinguishes between a conservative and a progressive selection (1980, p.74-85).

According to N.C. MARNEY and N.M. SMITH, "in **dynamic systems**... the whole business of natural selection... amounts to the automatic generation of **subsystems** that are specially resistant to the **perturbations** characteristic of some particular **subenvironment**" (1964, p.119):

Such a **mechanism** must be some kind of branching **self-organization process**, whose precise nature and workings have remained quite elusive until the recent development of **far-from-equilibrium thermodynamics**. A promising possibility to model branching **processes** has been signaled by St. KAUFFMAN in his book "The Origins of **Order: Self-Organization and Selection in Evolution**" (1993).

Order may emerge from **interactions** between **components**, as shown for instance by M. MARUYAMA's **deviation-amplifying mutual causal processes**, based on the effects of **rules** on some **initial state**, or in J. CONWAY's **models** known as "**Game of Life**", a particular case of **self-organizing automata**. According to KAUFFMAN, such **processes** may lead to the "**edge of chaos**", where the possibilities for innovation are maximal. This in turn opens the way to selection.

KAUFFMAN also hypothesizes that the general increase in **complexity** of systems (specially biological ones) progressively orients and restricts the role of selection. This could be a key to explain F. MEYER's **evolutive acceleration** (1954).

Complementary to this view is R. MARGALEF's: "Selection is a **filter**, but one that in turn evolves. There is a selection of **mechanisms** and motives for selection" (1980, p.93).

2952

SELECTION (Artificial)²⁾

→ **Evolution (Artificial), Fitness Function, Parallel distributed processing, Robot (Khepera), Synaptic weights**

2953

SELECTION (Frequency dependent)^{1) - 2)}

In polymorphic **populations**, some slightly different morphs may offer better **survival**. However, the favoured **forms** stay rare "because the commoner it gets, the more the selective pressure builds against it" (C. TUDGE, 1992, p.25).

In these cases, the **survival** value is inversely proportional to **frequency**. Only some **change** in the ecological **context** could alter this kind of **situation**.

It should be interesting to look for similar situations in societies in relation to some uncommon cultural types.

2954

SELECTION IN POPULATIONS (Combinatorial)^{2) - 4)}

This concept has been proposed by W.M.S. RUSSELL (1961, p.84) and may be resumed as well as generalized in the following fashion:

1. In any population widely scattered in a very diversified **environment**, new characters may appear at **random** in many different places;
2. If the **environment**, while diversified is not fragmented, no splitting of isolated populations will tend to happen and no new species will appear;
3. Thus the global pool of diversified characters will tend to increase;
4. Faced with even wide **variations** of the **environment**, the population will be able to adapt. Some characters will become widely represented and others numerically quite reduced. However, probably none will disappear totally.
5. **Variety** being globally enhanced, the population as a whole will have a greater **survival** potential.

The concept is related to, and explains **polymorphism**.

These ideas can be applied in quite a number of very different **situations**:

- In unstable climatic **environments**, as for example in West African Sahel, considerable genetic **variety** in cereals guarantee at least a minimum harvest, be the climate too dry or too rainy, and whatever kinds of pests are present and moreover, without any need for artificial fertilizer, pesticides or irrigation schemes.
- In human populations, according to RUSSELL. "Cultural rigidity... is accompanied by socio-economic decline" (ibid, p.58). This has probably been one cause of the demise of Soviet Union, and also of numerous archaic human groups and, in another setting, of many businesses stifled by authoritarian rule.

2955

SELECTION K ²⁾⁽⁴⁾⁽⁵⁾

A **co-evolution process** in which, in an **environment** whose all disponible **niches** are completely occupied by simple **forms**, the **selection** pressure leads to the appearance of more complex **forms**.

This is originally an ecological principle, which could be related to other systemic features in embracing complex systems.

One is LOTKA's **World Engine**, which gains global **efficiency** when more and more specialized (which generally means more complex) **transformers** become able to use some formerly unused supply of **energy**.

Selection K also could be related to the subdivision of **energy vortexes** leading to the qualitative differentiation of **channels** in **energy flows** (Ch. LAVILLE)

The **process** could moreover be related to the general **model** of **fractalization**.

Selection K could possibly be translated as a principle of social and cultural **evolution**, specially under the condition of historically growing use of **energy** by mankind.

2956

SELECTION (Multi-level) ¹⁾⁽²⁾

The existence of the **mechanism** of selection at different levels in life's **evolution** and **organization**

The idea that natural selection operates not only on individuals but also on **groups** has been first suggested by DARWIN. Groups may adapt to much more extended and complex **environments** than individuals. And, as some groups are more apt to discover good collective **adaptations** than others, being a member of a successful group brings a supplementary advantage to an individual.

A powerful objection to the value of group selection was that it would encourage cheats to benefit from the group without contributing to its progress. It seems in effect that most groups have their cheats (Be them "selfish genes" or parasitic bureaucrats). However, in case of coping with a really harsh **environment**, the group becomes much more intolerant to internal **parasitism** by cheats. Moreover, the group which tolerates too much cheating easily loses its selective advantage and may be eliminated by those who demand more solidarity of their members.

The collective and individual gains from group collaborative **behavior** or solidarity may even explain why **groups** tend to appear at different **levels** of **organization** and could be considered as the main root of **sociality**.

Evolution could finally offer an alternance of level selection among individuals and emergence of more complex forms of **organization**, later on again submitted to selection at a higher **hierarchic level** (J. MAYNARD SMITH & E. SZATHMARY, 1999)

→ **Cooperation as an evolutive process**

2957

SELECTION (Natural) ¹⁾

This widely debated concept is thus commented by P. CORNING: "... in fact, natural selection is an "umbrella" **category** that refers to whatever functionally-significant **factors**, (as distinct from, say, **stochastic** or **teleological** influences) are responsible in a given **context** for causing the differential **survival** of genes, genic "interaction systems" (in SEWALL WRIGHT terms), genomes, **groups**, **populations** and species" (1998b, p.3).

2958

SELECTION PRINCIPLE (LOOP) ^{1) - 2)}

A system favoured by **reward loops** obtained from other systems has a better **survival rate** than others who do not obtain such benefits.

H.T. ODUM who – in an implicate way – introduces this principle, observes however: "Either too much or too little **growth** by one **component** puts the loop out of harmonious **flow**" (1971, p.150).

And: "Species whose work efforts are not reinforced are shortly eliminated, for they run out of either raw materials or **energy**. They must be connected to **input** and **output flows** to survive" (Ibid).

The principle applies to many different kind of systems as for example: a cancerous growth, an invading weed, a successful business, a learning brain, etc...

2959

SELECTION (Replicative) ^{1) - 2)}

According to V. CSANYI, only **processes** that do not destroy the system are incorporated (which is self-evident) and, combined with other ones, enter in **self-reproductive cycles**.

CSANYI adds: "Any **organization** that cannot maintain its own **structure** is only temporary and irrelevant to **evolution**". Replicative selection works its way from the cellular **level** up to the whole **biosphere** (1989, p.78).

2960

SELECTION (The conditions of natural) ¹⁾⁽²⁾⁽⁴⁾

The following three conditions seem to be indispensable for natural selection:

- **reproduction** and multiplication of individuals of a certain type
- non-destructive (non lethal) **variations** in some of these individuals

- heredity or reproduction of these **variations**

A supplementary condition seems to be **variation** in the **environment**, which may have a positive or negative value for the **survival** of specific **variations** within the group.

Variations increases **variety** (in Ashby's sense) and becomes a favorable factor in a variable **environment**.

Selection reflects internal and/or external **constraints**.

Natural selection in species applies to species as **wholes**, but acts through the relative **fitness** of individuals, which in turn reflects **fitness** of their genes.

These concepts are very probably valid in all kinds of societies. In particular, the new emerging field of **Artificial Life** uses the three **processes** with the same results as to the "survival" and **growth** of the **colonies** of **elements** in a well defined **environment**

2961

SELECTIVE REPRODUCTION (in Artificial Evolution) ¹⁾⁽²⁾⁽⁵⁾

"Selective reproduction consists of a **linear** scaling of the **fitness** values followed by a probabilistic allocation of a number of offsprings proportional to the fitness value of each individual" (D. FLOREANO) et al., 2002-2003, p. 15)

This means that any individual (**robot**) is "born" with its proper set of characteristics. While adapting only its own **behavior**, any new characteristic can be transmitted to "individuals" of the next generation but only if compatible with the characteristics of other individuals.

It should be observed however that some aspects of this **process** are not yet really well understood and that debates and experiments are going on.

One of the participants states however clearly that "**learning**" ("apprentissage") must be distinguished from "evolution" (see also J.A. MEYER, 1998, p. 46-50)

The bridge crossing from LAMARCK to DARWIN still remains insecure!

→ **Animat; Artificial life; Neural network; Selection**

2962

SELECTIVITY ¹⁾

The ability of a system to select a satisfactory **response** to any stimulus.

Systems must constantly be able to select a convenient **response**, either to a **variation** in their **environment**, or some internal **perturbation** evoked by such a **variation** (directly or not).

The first condition to do that is to dispose of a suitable **choice** of possible **responses** (**Requisite variety law**)

If this condition is fulfilled, the **choice** still must take place. This is where selectivity enters.

According to H. SIMON, there are two basic kinds of selective **processes**:

"1. Various **paths** are tried out, the consequences of following them are noted, and this **information** is used to guide further search".

Of this first **process**, SIMON gives the following example: "...in organic **evolution** various complexes come into being, at least evanescently, and those that are stable provide new building blocks for further construction. It is this **information** about stable **configurations**, and not free **energy** or **neguentropy** from the sun (Note: which is, in any case, the prime mover) that guides the process of evolution and provides the selectivity that is essential to account for its rapidity"

"2. The second source of selectivity in **problem solving** is previous experience. We see this particularly clearly when the problem to be solved is similar to one that has been solved before. Then, by simply trying again the **paths** that led to earlier solution, or their analogues, **trial and error** search is greatly reduced or altogether eliminated".

"The closest analogue (in organic **evolution**) is reproduction. Once we reach the **level of self-reproducing systems**, a **complex system**, when it has once been achieved, can be multiplied indefinitely" (1965, p. 68).

2963

SELECTOR²⁾

Any device equipped with a preference **function**.

K. BOULDING, who tried to give a clearer content to the term, recognized himself that such a definition is nearly tautological (1972, p.68).

Moreover, the word preference is tainted with anthropocentrism.

Even so, the selector must necessarily contain some discriminating **description** of what it is supposed to reject or to select among the **inputs** received from the **detector**, and the capacity to transmit this **information** to the **effector**.

2964

SELF-¹⁾

A prefix used in many composed words, that indicates some **feedback** of the system on itself, or some reciprocal **feedback** between **elements** that tend to organize as a **whole**.

2965

SELF (The): A proposed systemic interpretation¹⁾⁵⁾

R. NUMMELA CAINE and M. CAINE resume as follows in systemic terms the self-concept as elaborated by a number of theorists: "The self

is a uniquely organized system made up of **beliefs**, biases, **memories**, predispositions, expectations, **knowledge**, fears, **reactions**, **behaviors**, talents and **meanings**" (1994, p.136).

What would be needed is a way to relate more precisely among themselves all these **components**... and moreover, give them an adaptive dynamics, i.e. an **autogenesis** and an **autopoiesis** of the self.

The authors contribute an interesting, if still partial, proposal to achieve this, namely their **concept of learning as self-reorganization**.

2966

SELF-ASSEMBLING^{1) - 2)}

The characteristic **behavior** of some **dissymmetrical** molecules, which tend to cluster together into more complex, but similarly **dissymmetrical** systems.

The self-assembling capacity can probably be considered as the very root of the basic associative **processes** in nature.

In G.M. WHITESIDES words: "Self-assembly omits the human hand from the building". While in some cases: "People may design the **process** and ... may launch it,... once under way it proceeds according to its own internal plan, either toward an energetically **stable form**, or toward some system whose **form** and **function** are encoded in its **parts**". (1995, p.114)

There are many natural systems which are self-assembling, from a simple raindrop to the human beings and societies.

Self-assembly has its roots in physics and chemistry, and still more deeply in **symmetry-breaking** in energetic **processes**. This is **thermodynamic** self-assembly.

This very basic **process** led to a more complex form of self-assembly in **living systems**. In WHITESIDES words: "The construction of a cell's **complexity** is balanced **thermodynamically** by **energy-dissipating structures** within the **cell** and requires complex molecules such as ATP... (p.116).

"The kind of self-assembly embodied by life is called coded self-assembly because instructions for the **design** of the system are built into its **components**" (Ibid).

According to WHITESIDES, our machines of the future will be much more complex than our present ones and based on self-assembly.

Self-assembly is closely related to **associativity**, **autogenesis**, **growth** and **form**, **order from order principle**, **slaving principle**, **so-ciogenesis** and **stigmergy**.

2967

SELF-ASSERTIVENESS¹⁾

"Characteristic of **holons** related to their existence as quasi autonomous **wholes**" (T.F.H ALLEN & T.B. STARR, 1982, p.277).

ALLEN and STARR comment: "This tendency is related to the **holon's** capacity to maintain its integrity. This aspect of **holons** pertains to the **constraint** that the **holon** asserts over its **parts**" (Ibid).

2968

SELF-CLOSURE EVENT²⁾

The first **interaction** between hitherto unconnected **elements**, leading to the progressive, but irreversible shaping of an **autopoietic system**.

"In general, it becomes quickly irreversible, but a long **morphogenetic process** is needed in order to materialize the potential thus created. What comes with self-closure is organizational **dynamics**.

"Self closure includes the following aspects:

- an **interface** or **boundary** appears, separating clearly and in a definitive way the new system from its **environment**, defining the internal **space** it controls ("invironment").
- within this **boundary**, the system asserts immediately its **autonomy**. It becomes able to **control** its **inputs** and to react to **stimuli** from its **environment**. Eventually, it becomes able to exert some **action** on it
- the system starts at once to differentiate its more or less complex **structures** and **functions**

These organizational **dynamics** are quite well known in the case of biological systems. However, they can be recognized under different guises in **social systems**, as for example:

- the birth of an enterprise
- the birth of a natural language

2969

SELF-DESTRUCTION OF SYSTEMS²⁾⁴⁾

No system seems able to survive eternally, save possibly the cosmos as a **whole**. But even this is merely an hypothesis that cannot be proved or disproved.

Systems can be destroyed by some independent **perturbation** in their **environment**, which eventually overwhelms the **limits** of their conditions of existence.

However self-destruction is very frequent. It can happen in different ways:

- The system may be taxing its environment excessively. A tragic example has been given by J. DIAMOND describing the undoing of Easter Island people (1995), possibly the most perfect example of Malthusian self-destruction by a **population** overtaxing a closed **environment**. DIAMOND wonders if this lesson would not apply to humanity as a **whole** in relation to planet Earth.
- Some **subsystem** of the system may turn **parasitic** and consume so much **resources** as to starve the system as a **whole**, making it unable to maintain itself.

- Some internal or external **parasite** may invade the system and also divert excessive **resources** for its own benefit. Cancerous **growth** would be a biological example.

- All systems seem to have a characteristic in-built **mechanism** which limits their **survival in time**: ageing in biological systems (for ex. **apoptosis in cells**); **sclerosis in human social systems**.

2970

SELF-EFFICACY

→ Efficacy (Self-)

2971

SELF-EXCEPTING FALLACY³⁾

The attitude of a researcher who reserves a special position for him- or herself.

Such a way would imply that the **observer** tries to put her or himself as possessing an absolute **ontological** certainty (G. DEVEREUX's "**Olympian stance**"). This cannot work when the researched subject or system is endowed with some degree of **autonomy**. Only "**trivial machines**" in von FOERSTER sense can be truly specified (and constructed) by an **observer**.

2972

SELF-FULFILLING³⁾

The character of an hypothesis or **forecast** that tends to foster this same hypothesis or bring about the **forecasted event**.

The self-belief in what is hypothesized or predicted exert an influence on the results of the research done or on the future **events**. Moreover, if the belief becomes shared by numerous people, the effect may become massive. Examples are the opinion polls, which may influence public opinion to the point of producing the predicted **event**.

2973

SELF-LIMITATING PHENOMENA^{1) - 2)}

This **class** of phenomena has been researched in 1960 by S. FOX in the realm of biochemistry and in relation to the origin of life. (1960, p.59).

Self-limitation is clearly a sine qua non condition in **complex systems** if they are to reach **dynamic stability**.

It seems to be a necessary consequence, or possibly even a cause of **autopoiesis** and **organizational** (or **operational**) **closure**. It is also quite probably related to **catalysis in hypercycles**. The subject should deserve a deeper investigation.

2974

SELF-OBSERVATION¹⁾²⁾

The capability of an **object** to observe itself.

In the case of human beings, this could be the root of **consciousness**.

However R. GLANVILLE states that "Every object is a self-observer" (1978, p.303), a quite enigmatic statement in the case of non-animated **objects**.

GLANVILLE adds: "Some objects observe other **objects**. Some objects are observed by other **objects**. However an object can be non-other-observing and non-other-observed" (Ibid.)

It would be interesting to find out if self-observation makes sense in a way or other for plants, animals (specially higher vertebrates) and societies.

2975

SELF-ORGANIZATION¹⁾

Ability of a system able to construct and change its own **behavior** or internal organization

The construction of self-organization is quite different from its **maintenance**, once the organization is completed. In the first stage, **morphogenesis** is important, even if the basic **template** of the system's organization is already present and acting. In the second stage, when general organization is stabilized, it should possibly be useful to speak of self-reorganization.

→ hereafter: "**Self-organization** (Two meanings of)", for more shades of meaning.

Self-organization is a very general type of **behavior** in systems. G. DALENOORT gives some examples: "Biological **evolution**; linguistics; crystal **growth** and lasers; social **processes**" Many others could be given. Self-organization has even been discovered in some geological **processes** (Stylolites spacing - E. MERINO, 1992, p.466).

According to DALENOORT, it can be studied from many different approaches "... which usually correspond to specific **choices of representation**". He also cites some well-known formal approaches: "**Cellular automata**; Petri nets; Mc CULLOCH-PITTS **nets**; **self-reproducing automata** (von NEUMANN)", and some specific **methods**: "**Autopoiesis** (MATURANA and VARELA); **synergetics** (HAKEN); **dissipative systems** (PRIGOGINE); **catastrophe theory** (THOM); evolutionary systems (LOTKA-VOLTERRA); chemical **auto-catalytic** systems (EIGEN)" (1989, p.16)

Self-organization could be considered as the acquisition of **variety** by the system by progressive reduction of its **redundancy in response to noise from its environment**.

As observed by H. SABELLI, so-called self-organization is inevitably at some initial **state** a co-organization **process**. He stresses that, as noted by J. PIAGET, **change** is not caused by a **cause-effect relation**, but by an **interaction** between **processes**, which constantly evolve (pers. comm.).

Or, self-organization is the progressive expression of an initial potential to acquire **heterogeneity** or **complexity** by a **process of differentiation** based on **energy dissipation**, as follows:

From **Homogeneity** to **Heterogeneity**

From **Redundancy** to **Variety** and **Complexity**

From Undifferentiation to **Differentiation** and **Organization**

However, the initial **state** can evolve towards more expressed **differentiation** only under the guidance of some original **template** (as for example the genetic **code** in a biological system or the original basic **values** in a socio-cultural one).

This initial **template** is obtained from some previous system or systems and is in itself a more or less complex "recipe" for **differentiation** starting from **redundancy** (for example all merystemes in a plant are **redundant**, but each possesses that potential for **variety** in the guise of the genetic **code**).

Self-organization, moreover, is a **process** of at least partial (i.e. never totally completed) **algorithmization** of the system and is closely related to **organizational closure and autopoiesis**.

It is obviously of fundamental importance in all **learning processes**.

J.L. TABARY emits the following objection: "If an increase of **organization** is to be significant, it must produce some perceptible gain in **efficiency**. This may be obtained by an increase of the number of **non-equilibrium stationary states**, which qualify the extension and precision of **accomodation** (Note: of the system to its **environment**). It can also be obtained by a more swift and less costly use of an adapted **stationary state**, to face some specific **event**". (1989, p.286)

This comment is important because it leads to a better **understanding** that an excessive self-organization may lead to block up and **sclerosis** when an excess of **adaptations**, frequently useless, leads to a ruined **adaptability**. Good examples are the bureaucratization **processes**.

E. LASZLO gives the following basic conditions for self-organization:

"First... it necessarily involves an **open system** (or a system coupled with another system)..."

"Second,... (it) presupposes some **inputs** from the system's **environment** which **stress** or **stimulate** the system in some way, i.e. which have the overall effect of **perturbations**..."

"Third, it is now understood that self-organization occurs in systems that have multiple **equilibria**... or several strata of potential **stability**".

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

"In view of these findings, self-organization can be explained on the general evolutionary principle of **fluctuations** induced either by **energy-flows** in the **milieu** acting on systems or by spontaneous **activity** by the systems themselves, inducing **chance variations** of **states**, some of which hit upon **levels of stability**" (1974, p.221).

The prerequisites for self-organization are somewhat differently stated (in accordance with the Brussels school of **thermodynamics**) by S.J. GAO and F.J. CHARLWOOD, as follows:

"Openness: The system must be open to the exchange of **energy, matter, information** with its **environment**;

"Non-equilibrium: The system must be in a **state** far from the **thermodynamic equilibrium**;

"Nonlinearity: there must be complex **non-linear** relations between the system's **components** (with multiple **feedback** and **feedforward loops**);

"Fluctuations: there must be microscopic **fluctuations** within the system which constantly test the **stability** of the macroscopic **state** of the system;

"Variation of environment: there is some structural coupling between the system and its **environment** and only the change of the **environment** can trigger the self-organization **process** in the system" (1993, p.58-59).

These conditions (save, possibly, the last one) do of course refer to an *already organized* system. There is a need to better connect the concepts of **autogenesis** and **autopoiesis** (and also **morphogenesis**) with **models** of self-organization, which describe either an incipient **process**, or a **dynamic equilibrium** condition.

The Swiss systemist E. SCHWARZ proposes a **meta model** of a "spiral of self-organization: ...the birth of a wide **variety** of systems displays a common succession of four states:

- 0) precursor tensions source of **instability**
- 1) noise or **fluctuations** (alea) triggering
- 2) a cascade of mutually provoked **events** (self-organization), which leads to
- 3) a new dynamically stable **structure-organization** of the system, followed by
- 4) a phase of actualization of the potentialities of this new system (**entropic drift** or trend toward the more probable)

"It must be noticed that the fluctuations in the alea sector do not always lead to a new viable **configuration** but, more often, end up with the **destruction** of the system or eventually with its maintenance with minor **adjustments**..." "A closer study of these **processes** shows that the **iteration** of such spiral **cycles** of self-organization and entropic drift generates a **long term** evolution toward **complexity** and **autonomy**, characterized by the successive appearance of six fundamental **loops** of increasing **abstraction**:

- 1- self-organizing **morphogenesis** (**positive feedback loops**)
- 2- **vortices** (recycling of **matter**)
- 3- **homeostasis** (**negative feedback loop**)
- 4- **autopoiesis** (self-production)
- 5- **self-reference** (between physical **structure** and logical organization), and
- 6- **autogenesis** (leading to **autonomy**)" (1998, p. 92)

2976

SELF-ORGANIZATION (Conditions for) ¹⁾

H. ATLAN states in the following way the conditions for self-organization:

"The initial **redundancy** must be high enough to start with, since it has the role of a potential for self-organization, to be reduced in the **process**.

"Some inertia must exist in the **response** of the system to **random perturbations** so that it is not going to be destroyed too quickly in order for the initial **redundancy** not to disappear right away. (A good example is that of liquid crystals and biological macromolecules where thermal **noise** can produce **changes** in conformation before it destroys the whole **structure** of the molecule, whereas the high repetitive order of crystals can exist only in one **form** and is completely destroyed almost at once when the "dose" of thermal **noise** – i.e. the temperature – reaches some **threshold**).

"Of course these are not sufficient conditions because the sufficient conditions have to do with specific **forms** of functional **organization**, i.e., with specific **functions** performed by the organized system, and giving a **meaning** to its **organization**" (1972).

In any case, as stated by M.B. HAWTON, self-organization becomes possible only if it initially has "... sufficient **preorganization** to run the first **cycle(s)** so as to generate the **information** which will be accumulated to organize future **cycles**. A machine can only become self-organizing through **operation**" (1974, p.87).

We are of course now burdened with the problem of **preorganization**. V. CSANYI introduced the useful concepts of **autogenetic system precursors**, **autogenesis** and **zero-system**, which shed some light on the subject. (1993)

2977

SELF-ORGANIZATION (Two meanings for) ¹⁾

There are two clearly distinguishable meanings for self-organization:

- 1- The progressive **process** by way of which a new **autopoietic system** with inherited and closely limiting characters constitutes its **repertory** of possible alternative **states**, all of them compatible with its **organizational closure**.

2. The progressive **emergence** of a system of a new type by **dissipative structuration** during a **process** of progressively overwhelming giant **fluctuations**, when over-abundant **energy** is at disposal.

An interesting comment on this second case by D. HERSHEY: "To describe the **behavior** of a self-organizing system we need some kind of index of the intensity of **energy dissipation**, which will provide us with a clue as to its organizing proclivity" (1986, p.6).

W. EBELING and R. FEISTEL add still a third type of self-organization, i.e. "dispersive self-organization (formation of a **soliton structure**)" (1982, p.11).

2978

SELF PRODUCTION versus SELF REPLICATION ¹⁾

- 1) Self-replication is (supposedly) the production by an **element** of another identical **element**.

- 2) Self-production is the **cycle** of reproduction of an organized system by itself.

Fenton ROBB states: "Self-replication" should not be mistaken for "self-production". The products of self-production of an **autopoietic process** may be quite different from these already comprising the system, if that is what is required to maintain its unity. A self-producing system may thus maintain its **process** by producing different **structures** with different **behaviors**. It may, in trying to maintain itself, produce novel **processes** and products, either with the present **structures** and **behaviors** or with new ones. For these reasons we shall not be able to distinguish simply by looking at their **structure**, or their **behavior**, **autopoietic systems** from those without that property. **Size, complexity** and **connectivity** may indeed be significant but do not of themselves provide us with diagnostic tools for the detection of **autopoiesis**" (1989, p.63).

Indeed, effective elementary self-replication seems to be a practical impossibility. The **element** would need a **template within itself** to make a copy of itself, and would thus be a **complex** system. Moreover, as the **template** must necessarily pre-exist, it must have been created somehow. Thus we are down back to the previous need:

- either of some kind of **meta-level recursivity**, as for example in biological systems, in which the genetic code seems to act as a **template**, but is provided by an hereditary mechanism, **recursive** at the species level
- or by evolutive **order from noise**.

The case of crystal **growth** within a saturated solution opens perhaps an interesting insight. Here, the **template** depends on the **lower level organization of complexity**, i.e., the **connection** mode of atomic electron shells within the molecule.

→ **Autopoiesis**

¹⁾general information

²⁾methodology or model

³⁾epistemology, ontology and semantics

⁴⁾human sciences

⁵⁾discipline oriented

2979

SELF-REFERENCE¹⁾ – 2)

The **behavior** typical of a system able to reproduce its own **elements** and their specific **inter-relations** without any need for outside intervention (and even in spite of such interventions).

This **behavior** is typical of the **living systems**.

J. BEDNARZ Jr. writes (1990, p.58): "Their specific **mode of operation (organization)** is not meant to be understood in terms of referring to something beyond itself – which would be the case with the introduction of the concepts of **purpose, goal or function**. Rather it is closed, referring constantly to itself through the alternate (re)production of **components** and complex of **component-producing processes**. Whatever takes place within them as *living systems* – whatever is accomplished by their **organization** – does so "... as necessarily and constitutively determined in relation to themselves because their being defined as unities through self-reference (is) their manner of **autonomy**" (quoted from R.H. HOWE & H.von FOERSTER, 1975, p.XIII).

Self-reference is also a characteristic of **languages** (as shown by this very work!). This may lead to well known paradoxical statements and contradictions. (crf. the famous case of EPIMENIDES, the Cretan, stating that all Cretans are liars). This problem has been finally eliminated by WITHEHEAD's and RUSSELL's **Theory of types**, and also produced in **systemics** two successive very important offsprings: **2nd. order cybernetics** (of the **observer**) and **autopoiesis**.

Some authors state that self-referential systems are "closed". It should be understood that this means merely "**organizationally closed**": the system necessarily maintains numerous exchanges with its **environment**, but these do not affect its basic **identity**.

It is however to be noted that, in the words of N. LUHMANN (1995, p. 5): "...self-reference can only exist in an **environment** and only in relation to an environment. Or, with a different expression, that self-referential **operations** and system/environment differences mutually imply - and even more: logically imply each other".

And: "In the theoretical **situation** a new conceptual trinity sets new accents: it is the triad "**autopoiesis**, "**operational closure**", and "**structural coupling**". The concept of autopoiesis transfers the principle of self-reference from the structural to the operational level".

The system could not maintain itself without **activity** and its activity is in fact re-activity. It is experiencing with its environment through the "structural coupling" that feeds the autopoiesis of the system.

And, by the way, that saves it from entropic dissolution and /or **solipsism**

2980

SELF-REFERENCE IN LOGIC²⁾ – 3)

A.N. WHITEHEAD and B. RUSSELL definitively established in "Principia Mathematica" the necessity to exclude self-reference in logical statements, in order to avoid paradoxes and contradictions.

This excludes any "... self-referential utterances, statements, propositions, **descriptions**, etc.", as stated by R.H. HOWE and H.von FOERSTER (1975, p.1).

A curious result of this discovery is that **languages** are somehow **autopoietic systems**, able to produce only a limited – while enormous – number of statements, in accordance with their own combination **rules**, which by no means guarantee their logical soundness.

The self-reference problem is also related to **GÖDEL's Incompleteness theorem**.

→ **Logical types**

2981

SELF-REGULATION¹⁾ – 2)

The **process** by which a system is "able to modify its own **behavior** in order to enhance the **production of the desired output**" (after B. BANATHY, 1973, p.88).

It would seem that the self-regulating system is firstly able to maintain itself within its own **limits of dynamic stability**. According to E. JANTSCH, self-regulation is possible in a system "...in which **positive** and **negative feedback processes** would counteract each other sufficiently to warrant only a minimum of human intervention" (1975, p.272). This is obviously the case of many natural systems.

One could however conceive that a system could project itself out of its **stability** band precisely by trying to 'overdo' its performance: it could be the case of many **human systems**.

2982

SELF-REORGANIZATION²⁾⁽³⁾⁽⁴⁾

A more or less general re-arrangement of the **structures** and **functions** in a system.

Surprisingly, this **phenomenon** has not yet attracted a wide attention.

It is however a quite general one, of which numerous and varied examples are known: the molting of insects, crustaceae, and some vertebrates..., deep change in human **organizations** (re-engineering! - political and social mutations) and overall psychical (religious conversion for instance) or mental **transformations** (personal or at the **level** of so-called collective **paradigm shifts**).

Self-reorganization supposes the **decay** and dissolution of a specific ordering of the **elements** of the system and deep **perturbations** and even replacement of the existing **processes**.

However, this quite general loosening and unravelling of **organization** does not destroy some deeper plan or blueprint, which remains as a basic **template** for a new ordering.

CSANYI's **autogenesis models**, MATURANA's **autopoiesis** and PRIGOGINE's **dissipative structuration in systems far from equilibrium** could be useful in order to reach a better **understanding** and a good general **theory** of self-reorganization.

→ **Aura; Resilience**

2983

SELF-REPLICATING LOOP³⁾⁽⁵⁾

An **algorithm** that allows an **automaton** to produce copies of itself

Until now, such devices are merely **computing models**

M. SIPPER and J.A. REGGIA write: "Although various teams have created **cellular automata** in electronic hardware, such systems are probably too wasteful for practical applications: automata were never really intended to be implemented directly. Their purpose is to illuminate underlying principles of **replication** and, by doing so, inspire more concrete efforts"(p. 35, 1991)

The authors do comment about the possible creation of physical replicating **machines** and the disquieting question marks about their eventual relations with humanity (p. 35)

2984

SELF-REPRODUCTION²⁾

1. The capacity of a system to reproduce its own **elements** and the characteristic **network of interactions** between them.

This definition corresponds to the property of **autopoiesis** and its complement, **organizational closure**.

2. The capacity of a system to generate another system endowed with the same characteristics as itself.

This definition corresponds to J.von NEUMANN concept of self-reproducing "**automata**".

2985

SELF-REPRODUCTION

→ **Autopoiesis**

2986

SELF-SIMILARITY²⁾

Property of some **sets** such as each **part** at different **levels** is similar to the **whole**.

This is particularly the case with **fractals**, whose **forms** do repeat in a similar way through decreasing dimensional **scales**.

Some examples of self-similar sets are:

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

- CANTOR's set, obtainable by sequential suppression of the median third of a segment (a **process** that could theoretically be repeated ad infinitum, which is also the case in the following examples)

- von KOCH's curves
- SIERPINSKY's sieves and carpets
- PEANO's curves
- MENGER's sponges (see J. GLEICK, 1987)

Self-similarity is a powerful **algorithm** for **compressibility**. It is related to **chaotic attractors**, through **period-doubling sequences**.

Self-similarity is also the most important property of **holograms**.

J. GLEICK explains that self-similarity: "... implies **recursion**, **pattern** inside **pattern**. MANDELBROT's price charts and river charts display self-similarity, because not only do they produce detail at finer and finer **scales**, they also produce detail with certain constant **measurements**" (1987, p.103).

As GLEICK states: "The self-similarity is built into the technique of constructing the curves – the same **transformation** is repeated at smaller and smaller **scales**" (ibid).

The first and best known example of self-similarity is found in the **Golden Proportion** of the ancient Greeks. Self-similarity is also related to **chaos** and **renormalization**.

It was independently discovered by K. WEIERSTRASS as his continuous, non-differentiable **function** (See hereafter).

→ also: **ELLIOTT waves**; **Fields within fields**

2987

SELF-SIMILARITY in the WEIERSTRASS FUNCTION ²⁾

B. WEST and A. GOLDBERGER explain: "His **function** was a superposition of harmonic terms: a fundamental with **frequency** Ω_0 and unit **amplitude**, a second **periodic** term of **frequency** $b\Omega_0$ with **amplitude** $1/a$, a third **periodic** term of **frequency** $b^2\Omega_0$ with **amplitude** $1/a^2$, and so on. The resulting function is an infinite series of **periodic** terms, each term of which has a **frequency** that is a factor b larger than the preceeding and an **amplitude** that is a factor of $1/a$ smaller. Thus, in giving a functional form to CANTOR's ideas, WEIERSTRASS was the first scientist to construct a **fractal function**" (1987, p.360).

The WEIERSTRASS function offers some singular properties: "Because of the infinite **layers** of detail, one cannot draw a tangent to a **fractal** curve, which means that the function, although continuous, is not differentiable" (ibid).

Its **mode** of construction implies that the curve is self-similar at any **level**. It also can be properly interpolated in a continuous way, however acquiring more and more closely defined values at microscopic **levels**.

At any chosen **level** the curve is a **fluctuation** of the more macroscopic **level** and the median of the immediately inferior **level** of **fluctuations**.

Moreover, any WEIERSTRASS function has its proper measure of self-similarity, in terms of **frequency** and **amplitude**, "which is precisely the **fractal**, or HAUSDORFF dimension: $\log_n a / \log_n b$ " (ibid).

The WEIERSTRASS function is a "**scaling** relation, often called the **renormalization group transformation**" (ibid).

Its analogy – unfortunately rather imperfect – with embedded complex cyclical **processes** is striking.

See: "**equilibria (levels of)**"; "**cyclical or periodic**".

→ See also "**Resonance**"

2988

SELF-SIMPLIFICATION ²⁾

This is an evolutionary **process** postulated by H. PATTEE, as indispensable to complement mutation by **random search** and subsequent **selection**, which must be considered in his opinion as quite an insufficient explanation for **evolution** (1972, p.39).

PATTEE sees self-simplification as a jump from one **level of complexity** to the next higher one, more or less akin to SIMON's **Hora and Tempus** metaphor.

It implies **self-description** through a **code**, i. e. "... a new **hierarchical level** of (self) **description** which selectively ignores the trapped details at the lower **level**" (p.39).

Self-simplification could result, through the steering power of such a **code**, from the appearance at the higher **levels** of specific (i.e. **constrained**) **networks of interrelations** between very numerous **elements**. In this way **composite systems** could conceivably produce **complex systems**, as for example in the social phase of the amoeba *Dictyostelium discoideum*.

It could also possibly correspond to N. ELDREDGE and S. GOULD concept of punctuated **evolution**, as well as to biological ordering through genetic **codes** and social **order** through **values** and **norms**.

2989

SELF-STABILIZATION ^{1) - 2)}

The capacity of a system to pass from **growth** to **steady state**.

No **dynamic system** can survive for long **time** if it cannot control, limit and finally stop its own **growth**, because it finally crosses a **threshold** where neither its internal **structure** maintains anymore its **coherence**, nor its **environment** remains able to feed it its needed **inputs**.

Genetic **controls** (not yet clearly understood) take care of self-stabilization at the biological **level**.

The stabilizing devices in societies are still more enigmatic and would constitute a rich ground for systemic **inquiry**.

The subject seems closely related to **autopoiesis** and **organizational closure**, as well as **morphogenesis** and **morphostasis**.

2990

SEMANTIC AMBIGUITY ³⁾

Any problem of **meaning** interpretation arising from imprecise use of **interconnections** between **semantic units** in a **semantic net**.

E. BUCHBERGER gives the following example:

"I see the man with the hat"

"I see the man with the binoculars"

Only the semantic or the observed context would suppress the **ambiguity** of the second sentence. For another type of **ambiguity**, see "**semantic unit**" (1987)

2991

SEMANTIC CLOSURE ^{3) - 5)}

Self-catalysis of language and **autopoiesis** in its uses.

"An **entanglement** of symbolic **controls** and material **constraints** which is closed on its **semantics**". (H. PATTEE, 1982)

Semantic closure results of the **interactions** between basic **constraints** in a **language**.

H. PATTEE, who introduced this quite abstract notion, applies it to any kind of **languages**, starting with molecular biology. He writes: "A generalized **language** might therefore be characterized in a simple chain of **constraints** that controls the construction of complex **patterns**" (in KLIR, 1991, p.583-85).

In a human language for instance, there are phonetic **constraints** at one **level** and orthographical, grammatical and syntactical ones at other **levels**.

Semantic closure is characteristic of **self-reproducing organisms**. L.M. ROCHA comments: "The principle of semantic closure entails symbolic **messages** that code for compounds of material **parts**, which will themselves organize" (1996, p.380)

→ hereafter.

2992

SEMANTIC CONSTELLATION (SeCo) ¹⁾²⁾⁴⁾

"Dynamical **networks** of **elements/processes** extending transversally through different **levels** of the mind-body-psyche system"(C. HARDY, 2001, p. 37)

"These networks...are created through the interplay of experimental uniqueness, cultural influences and genetic **constraints**...

"The SeCo can thus range from a highly personal and idiosyncratic **organization** (artistic skill, specific feelings, etc...) to one that is partly constrained by social **consensus** (driving, playing tennis, etc...)" (Ibid.)

The Semantic Constellation concept is close to the **mental frame** concept (WARFIELD) or the **frame of reference** one (FRANÇOIS). All of these try to explain how we construct, use, and sometimes modify our mental **structures** (or possibly our neuronal connexions in our cerebral cortex)

HARDY also observes that in a SeCo, "the mode of **interaction** between levels and processes cannot be simply hierarchical" (p.39)

She states that: "...the SeCo – as dynamical network is...self-organized" (p. 40) and that "a healthy psyche is characterized by SeCos that remain labile" (sic)

Also: "...one aspect of SeCo **dynamics** lends itself well to VARELA's concept of "mutual constraints" (Ibid.)

These constraints are biological, or interpersonal, or social. Moreover "these organizing factors are not intrinsic, but mostly **historical**" (Ibid.)

Training, learning and generally **education** give themselves in that historical dimension.

In a similar way, "in a specific SeCo, integrative and conative **processes** act as predominant organizational forces in the **configuration** and **transformation** of the SeCo " and "through the need for understanding (the attribution of **meaning**) and a need for **coherence** "the SeCo turns operative as "intentions and anticipations seem quite pervasive" (Ibid.)

→ **Semantic Field- Webs (Multilevel)**

2993

SEMANTIC CORRELATION SYSTEM ¹⁾²⁾³⁾

"A **methodology** for **information** processing systems based on the possibility to compute semantic proximity between texts in reference to thesauri" (G. MINATI, 1994)

Minati adds: "Such a **computation** takes place by considering words, **structures** of words, structures of structures in specific **contexts** and by considering semantic correspondences between words, structures, structures of structures and conditional structured synonyms"

Such a computation could be very helpful to reach a more integrated **understanding** of the general nature and **meaning** of the systemic (and cybernetic) **meta-language**.

2994

SEMANTIC FIELD ²⁾³⁾⁴⁾

The **network** of all the concepts and ideas (expressed in words) as related to one chosen specific concept.

V.V. NALIMOV shows as an example, the set of **connections** that can be constructed around the concept of freedom (1982, p. 214-219)

In fact, Nalimov's **graphs** are only connected and weighted listings, i.e. a kind of static (and statistical) census.

A true semantic field should be multi-connected. It could for example be theoretically possible to draw, under the form of a very complex graph, the multiple interconnections of all the terms in this encyclopedia. We would of course obtain in this way a gigantic and hyper-complex map, whose global understanding would be excessively difficult.

However **nodes** that would appear in the map, would make it easier to catch its general **meaning**..

C. HARDY writes: "According to Semantic Field Theory, the basic dynamic of the mind is a connective, dynamic, instantiating spontaneous **linkages** between **elements/processes** within **Semantic Constellations** or between these" (2001, p. 41)

HARDY, who proposes the semantic field concept, adds that "in these dynamical **networks**...the most pervasive interactive process is that of inter-influences, which VARELA calls "reciprocal influences".

Of course "...there often exist global **patterns** that harmonize the system..." (such as **values, goals, feelings, etc...**)

HARDY speaks of an "ordering principle", which is of course a basic feature of any field.

However she does not describes this principle in detail. One could imagine that it resides in the reciprocal **constraints** resulting from the nascent and growing **interactions** among elements and processes.

About " **values, goals, feelings, etc** "Nalimov concedes that any dictionary should be considered " as a filter given by our **culture**" (p. 214). We would add "...and by our viewpoint. For ex. It is obvious that the concepts of " system" and " feedback" are the basic organizers of the specific semantic field reflected in this Encyclopedia...and are moreover as such rooted in Western culture

→ **Autogenesis; Determinism (Chaotic); Semantic Constellations; Sociality; Supremacy of the complex; Webs (Multilevel); Zero System**

2995

SEMANTIC FILTER ³⁾⁵⁾

G.L. FARRE states: "A semantic filter results form the projection of a **semantic matrix** onto some corresponding type of **observation space**" (1998b, p. 266)

For example, while the semantic matrix of the meteorologist and the one of the climatologist have many common features, they differ:

- 1- by the **time dimension** of their research
- 2- by the way they interconnect the results of their **observations**

FARRE expresses this in the following sentence: "Thus construed (Note:i.e. on the base of a specific **semantic matrix** mediating into a specific **language** by a **syntax**), the semantic filter effectively defines the *universe of discourse U* of the language, which is the **domain** of *what* the language is about, what it describes and what the operational end of the semantic filter is designed to probe: the observations are thus theory laden" (p. 267)

2996

SEMANTIC MATRIX ³⁾

"The **process** by which a **context** independent conceptual **structure** is brought to bear on inherently local **observations**" (G.L. FARRE, 1998 b, p. 266)

Systemics and cybernetics constitute wide transdisciplinary conceptual structures that can be used to process any kind of observations in a specific discipline in the sense to interrelate them at their own disciplinary **level** and, on the other hand, to other types of observations at the same or different levels made in the **frame** of other disciplines

Any semantic matrix produces a specific **semantic filter**

2997

SEMANTIC NET ³⁾

A **network** of **meaning** bearing **elements** (or **nodes**) interconnected through specific (i.e. specified and oriented) **links**.

Any **language** is a semantic net. The systemic and cybernetic **language**, object of this work, is an example.

M. BODEN makes some interesting observations: "The concept of semantic net originated in psychology. It depicts human **memory** as an associative system wherein each idea can lead to many other relevant ideas, – and even to 'irrelevant' ideas, linked to the first by mere coincidence... A semantic net consists of **nodes** and **links**. The **nodes** stand for specific ideas, while the **links** – whereby one idea can be accessed from another – represent various types of mental **connections**... The '**meaning**' of an idea represented within a semantic net is a function of its place in the system. It involves not only the **node** specifically labelled for the idea in question (*violet*, perhaps) but also the **nodes** that can be reached, directly or indirectly, from that **node**... Adding a new **node** will implicitly affect the **meaning** of all the existing ones..." (1990, p.95-6).

The semantic net **model** represents a **conceptual space** and is closely related to **connectionism** which "associative **memory**", grounded in both **meaning** and **context**" (p.119).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

2998

SEMANTIC NOISE³⁾

1. "Any feature of the **message** that reduces the sharpness of the selective operation on the required subspace." (D. Mac KAY, 1969, p.74)

This somewhat abstract formulation means that, as any question specifies an area in which required **information** helps to make **meaning** more precise, anything that confuses or obscures that **information** is "noise" in a sense akin to the perturbing noise in a physical **channel** of **communication**.

Semantic noise, however, is different from irrelevant **information**.

2. "**Ambiguity** in the denotation or connotation of a **message**" (R.L. ACKOFF and F.E. EMERY, 1972, p.182).

These authors state: "A **message** may be misinterpreted – that is, *B* responds to the wrong thing – and still produces the type of **response** intended" (Ibid).

Misinterpretation is the result either of sloppy semantics from the sender (who does not consider the possibility of **ambiguity** inherent to the **situation**) or imprecision in the **code** itself.

In some critical cases, the **message** cannot be interpreted if the **situation** is not well known.

2999

SEMANTIC PRIMARY⁵⁾

"A signification bearing unit that cannot be further decomposed" (E. BUCHBERGER, 1987, p.79).

The existence of truly primary semantic units seems doubtful to this compiler. As an example, even very basic systemic and cybernetic concepts as **energy**, **matter**, **space**, **time** or **information** and **entropy** are not the result of a "decomposition" and cannot be defined without reference to other units.

This doubt is also expressed by E.von GLASERSFELD: "Experience has shown that one rarely succeeds in isolating and defining a semantic **element** the first time it crops up in an analysis; it is only when the same **element** is found to be relevant in the analysis of other verbs that it gains contour and becomes more satisfactorily defined" (1988, p.20).

The same author speaks of complexes of "semantic nexus" (p.39).

However, the semantic primary concept is certainly useful in classical **Artificial Intelligence programming**.

3000

SEMANTIC PROCESS³⁾

A **cognitive process** that tends to evoke a supposedly **adaptive behavior** in some **situation** deemed analogous to some formerly memorized one.

F. and P. LAVIGNE distinguish two fundamental steps in the semantic process:

- 1) to faithfully perceive and semantically recognize **events** in the **environment** and
- 2) to dynamically anticipate possible future **events** (2000, p. 5)

They explain how formerly stored **associations** between some frequent similar **sequences** of events prepare the **recognition** in new situations of also seemingly similar sequences, yet incomplete.

This focuses the attention on the **probability** that the current sequence should lead to similar (or possibly dissimilar) results. This **anticipation** will then generate some adaptive behavior (Ibid)

3001

SEMANTIC REACTION³⁾ – 4) – 5)

"The psycho-logical reaction of a given individual to words and **language** and other **symbols** and **events** in connection with their **meanings**, and the psycho-logical reactions which become **meanings** and relational **configurations** the moment the given individual begins to analyse them or somebody else does that for him" (A. KORZYBSKI, 1950, p.24).

Let us observe that the author writes "psycho-logical", with hyphen, to emphasize the existence of both aspects in psychological attitudes. Semantic reactions are related both with the emotional and the mental **levels** in the nervous system, with a natural **dominance** of the former one.

KORZYBSKI comments: "It is of great importance to realize that the term "semantic" is *non-elementalistic*, as it involves conjointly the "emotional" as well as the "intellectual" factors". and... "The term *semantic reaction* will be used as covering both semantic reflexes and **states**" (p.25).

The basic point about semantic reactions is that **meanings** are never totally objective and absolute. They depend on the specific organizational psycho-logical **closure**, as well as of the cultural **environment** of the individual.

The Cross for example is a **symbol** revered by Christians, but may evoke negative reactions from a Muslim and no definite reaction at all from heathen who never heard about Jesus. Moreover, these reactions are automatic, not submitted to any voluntary **control**.

Semantic reactions can be very dangerous from the psychopathological viewpoint. KORZYBSKI proposed a whole psychotherapy based on the reeducation of semantic reactions in his work "Science and Sanity". Unawareness of semantic reactions also implies a great potential sociocultural risk, since they can easily be manipulated by ideologues, agitators and schemers.

3002

SEMANTIC SPACE³⁾

The global **field** of **meanings** of any word as it is used within the **limits** of a given **language**.

CH. HENRY thus explains this concept: "... words take their **meaning** in part from other words around them in a sentence or paragraph or, one might add, any verbal **construct** that supplies **context**" (1992, p.695).

Moreover "... the non-literal **meaning** of a word is governed in large part by its **context**" (Ibid).

It could even be said that words within a sentence or a discourse lose a part of their **identity**, just as electrons in atoms, atoms in molecules, molecules in **cells** and individuals in societies.

3003

SEMANTIC UNIT³⁾

"A whole group of words or even of sentences acting together, rather than single words acting in isolation." (D. Mac KAY, 1969, p.29)

This definition may be extended towards nonspoken or written expressions. A red stop **sign** at a crossroads or the ominous roar of thunder, or for a mouse in a field the shape of a sparrowhawk in the sky are somehow bearers of **meaning for whom has been trained to understand them** (see "**semiosis**").

On the other hand, any **language** may be considered as a matrix of countless semantic units.

As noted by G.M. WEINBERG, not only the **interrelations** between words, but even implicit **syntactic** and semantic **knowledge** by the users of the **language**, are conditions of correct interpretations and suppression of ambiguities. He submits the following amusing example:

"TIME FLIES LIKE AN ARROW"

"FRUIT FLIES LIKE A BANANA" (1975, p.65)

and uses it to show the difficulties in resolving ambiguities in computer **programs**.

3004

SEMANTICS³⁾ – 5)

"The theory of the relations between the **signs** and the **objects** symbolized by them (**designata**)" (D. GERNERT, 2000 a), p. 155) "...and more specially, the study of the **meanings** of words..."

The study of the **meanings** of words, of their use in **languages** and the adequacy of this use for the **representation** of reality and as a means of **communication**.

Semantics is that part of **semiotics** which is restricted to the spoken or written **signs**.

3005

SEMANTICS (General) ³⁾ - ⁵⁾

A psycho-logical general theory of the relations between **perceptions**, physiological **reactions** to them, mental elaborations and resulting effective and verbal **behavior**.

General semantics was introduced by A. KORZYBSKI, in his famous work "Science and Sanity" (1933). It covers a much wider area than what is commonly known as semantics, including important insight in logics, **epistemology**, physiology, psychology, psychiatry and **learning**.

Its global approach is closely related to **systemics**, as for example to von FOERSTER concept of **observing systems**.

KORZYBSKI advocates for a psycho- and even physio-semantic re-education in order to avoid conceptual disorder and confusion, leading to mental alienation, at individual and social level. He developed the concept of **non-identity** of **elements** and systems in space and time and insisted on the danger of **spurious identifications**. This includes the necessity to avoid confusion between our **abstractions** and concrete reality, a sine qua non condition of mental equilibrium and health.

The main features of General Semantics are as follows:

- **Knowledge** is circular: We must distinguish: "between the inherent **circularity** of "human **Knowledge**", which must start with **sets** of undefined terms, and so start with **some knowledge**; and circular definitions or explanations which define or explain nothing" (1950, p.759).

Progressively deepen the **contents** of the unavoidable basic tautologies is not the same as become unconsciously and passively ensnared in tautological circles, that, through verbalizations without new **contents**, block us from any progress toward **understanding**.

- Taking conscience of the different **orders of abstraction**: KORZYBSKI warns against what he calls the danger of "objectification" of words, remembrances, etc..., i.e. granting a factual reality to mental **constructs**, or burden **perception** of reality with **abstractions**. For example, "**dynamic stability**" does not exist independently from concrete and observable systems which are dynamically stable, *each in its own way*.

Moreover, we should take conscience of the various **levels of abstraction**. It is never possible to describe completely the **fact** or **event** in itself: From my dog "Max" as I see it at this fleeting moment, to the generalized abstraction "living being", there is a whole **scale** of more and more abstract "**labels**". In KORZYBSKI's words: "... the most usual **identification** of different **higher order abstractions** appears as the confusion of inferences and inferential terms with **descriptions** and descriptive terms" (p.443).

KORZYBSKI created a kind of mnemotechnic **model** of **scales of abstractions**, the so-called "**structural differential**" (fig. p.558), which is very useful to train the mind for correct acknowledgement and differentiation of the various **levels of abstraction** (p.393-8).

- **Non-identification**: KORZYBSKI advises training oneself in non-identification as a way to psychological and mental sanity. He considers abusive **identifications** as the root of multiple psychological and socio-political problems. Only non-identification prepares us to perceive and understand **new** and unexpected **behavior** in systems, resulting from **interactions** between their **parts**, or with the **environment**, that had never been observed in the past.

Non-identification also prevents us to stick unwarranted significance to some **events** because we tend to give them the same **meaning** that we gave to former **apparently similar events**.

Finally, **radical** non-identification helps us to understand that **every event, fact or situation** is fleetingly **unique** in **space-time** and that, consequently, generalizations should be avoided or made with utter care.

- **Semantic reactions**: According to KORZYBSKI we live our lives in emotional subjective **levels**, generally unexpressed, but not in verbal **levels**. These are merely auxiliary, sometimes useful (when well adapted to circumstances), and sometimes harmful (when otherwise). This is a result of our ignorance of our own semantic reactions which burden our ways to communicate with others.

KORZYBSKI thus proposes to "break the old elementalism" and replace psychology by "psycho-logics" to emphasize the interplay between the emotional (unspeakable, or at least unspeakable) **level** and the mental one (p.23-24). This type of problems was later on further explained by the French biologist H. LABORIT (1954, 1970, 1976).

KORZYBSKI's ideas are moreover consonant with von FOERSTER's **2nd order cybernetics** and with MATURANA and VARELA's **organizational closure**.

- **Time-binding**: Man, and probably all living beings to a lesser extend, are somehow connected with themselves through **time**, by way of physiological and nervous devices (1950)

In "Science and sanity", KORZYBSKI develops various practical training **methods** to re-educate **behavior** in a better psycho-logic way.

→ **Non-identity**

3006

SEMANTICS (Pathological) ³⁾

H.von FOERSTER persistently denounces the sloppy use of terminology in systems and **cybernetics**.

He gives some glaring examples:

"When engineers talk about a computer's **"memory"**, they really don't mean a computer's **memory**; they refer to devices or systems of devices, for recording electric **signals** which when needed for further manipulation can be played back again. Hence, these devices are **stores** of **storage** systems... The content of these **stores** is a **record**" (1981, p.236).

As von FOERSTER once observed in a lecture, we thus come to believe erroneously that the electronic engineers know what **memory** "is" and, adopting the false **analogy**, we look for **stores** of **data** in some precise place in the **brain**.

Another example is the term "**problem solver**" applied to computers: "Of course, they are no **problem solvers**, because they do not have any problem in the first place. It is *our* problem they help us solve like any useful tool, say, a hammer which may be dubbed a "problem solver" for driving nails into a board. The danger in this subtle **semantic** twist by which the responsibility for **action** is shifted from man to a **machine** lies in making us loose sight of the **cognition** problem" (Ibid., p.237).

Another example widely developed by von FOERSTER are the numerous semantic abuses on the term "**information**", principally originated in the common delusion that **data** are **information**, while only their **understanding** and ordering by our **brain** in **interrelations** clustered in **reference frames** becomes **information**.

3007

SEMI-LOGARITHMIC GROWTH

→ **Logarithmic growth (Semi); Optimum (Dynamic); Ratio scale**

3008

SEMIOCHEMICALS ⁵⁾

A general term for hormones and **pheromones**. The neologism is introduced by T. STONIER (1997) and considered by S. BRIER as "not a bad term"

Other biochemicals as for example Adenosine Triphosphate (ATP) and ADN and ARN could, it seems, be added to the list. So could the intersynaptic chemicals in the **nervous system**.

Generally speaking, the new term aims at conveying the **information transmission value** of these chemicals and their role in bi-and multiple **relationships** and, as a result, as **agents** of **sociality**.

→ **Infon**

3009

SEMIOLOGY ⁵⁾

The science that deals with the **significance** given to **signs**.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

From the systemic viewpoint, semiology is closely related to the way our **perceptions** lead to the construction of **networks** of interconnected and coherent **meanings**, in the **brain** and nervous system.

According to E. BENVENISTE, the semiotic **sign** is recognized before it can be used. Semiotics thus precedes **semantics**, which results of an activation of the **signs** within a **language**.

3010

SEMIOSIS²⁾

C.S. PEIRCE, quoted by U. ECO, wrote: "By semiosis I mean an **action**, an influence, which is, or involves, a **cooperation** of three subjects, such as a **sign**, its **object** and its interpretant, this tri-relative influence not being in any way resolvable into **actions** between pairs" (1979, p.15).

Semiosis tends to be an ongoing **process**: "... in order to establish what the interpretant of a **sign** is, it is necessary to name it by means of another **sign** which in turn has another interpretant to be named by another **sign** and so on" (Ibid, p.68).

Semiosis thus parallels somehow the ever-branching circulation of **meanings** within a **semantic network**.

Note: Ch.S. PEIRCE spelled "semeiosis" in lieu of "semiosis". The same observation has to be made about "semiotics" or "semeiotics"

3011

SEMIOSPHERE²⁾⁴⁾

The whole set of living **organisms** able to communicate through their interpretation of a variety of **signs**

GOPPOLD comments: "In the diction of MATURANA (1987) and LUHMANN (1993), **social systems** and proto-social systems arise in the behavioral **coupling** of organisms, which is another way to look at the Semiosphere.

The Semiosphere is the comprehensive concept for all *ontogenetic pattern transmission in the biosphere*. In the case of organisms with higher neuronal systems, like mammals and birds, the behavioral coupling is effected by **neuronal resonance**" (2000, p. 108)

Even more archaic **communication** through **pheromones** or other biochemical products takes place in **ecosystems**. In these cases the **behavioral coupling** is also obvious. In a somewhat dubious way, we could possibly speak of proto-semiotics

3012

SEMIOTIC BIOLOGY

→ **Biosemiotics**

3013

SEMIOTIC LIBERTY¹⁾

Degree of freedom of a system in relation to its **constraints** (D. Mac KAY, 1969, p.48)

"The relative extension of the **code** and the logical possibilities for combination within the **message** do control the informational possibilities of the system and thus, its organization" (p.48).

3014

SEMIOTICS^{3) - 5)}

"The study of **signs** and **symbols** and the way they program **behavior**" (J.Z. YOUNG, 1974, p.298).

Semiotics was introduced by C.S. PEIRCE, who defined it as "the necessary **laws of signs**".

YOUNG adds that **signs** can be "...transmitted as **language** or by gesture, smell, touch, or in any other way" (Ibid).

Ph. GUDEMI explains PEIRCE semiotics as follows: "In semeiotics (sic), something can serve as a **sign** of something else by being an **icon**, an **index** or a **symbol**...An icon serves as a sign by resemblance to something else, like a portrait to the person portrayed. An index serves as a sign by pointing to other things, which are associated with it in a potential "causal" manner, like a cloud to possible or actual rain (The use of **causality** is meant mainly as illustration, since the philosophy of **causality** is itself full of a number of vexing **issues** and semeiotics should not be held hostage to it). And a symbol is an agreement that something will stay for something else, independently of any iconic or indexical **relationship** the one has to the other; words in human **language** are the most typical exemplar of the symbol" (2000, p. 134)

(Let us remember the ironic MAGRITTE's painting titled "This is not a pipe", precisely *representing* a pipe).

Gudemmi's paper also explains very clearly other Peirce's terms, among them: firstness, secondness, thirdness and interpretant. He relates Peirce's **phenomenology of experience** to MATURANA and VARELA's **structural coupling**.

Note: For various important papers about Peirce, see KAUFFMAN, L.H. and BRIER, S. (2001)

D. GERNERT offers the following synthesis of the role of Charles W. MORRIS in the history of semiotics: "Starting mainly from some specific parts in the extensive work of Charles S. PEIRCE (1839-1914), the American philosopher Charles William MORRIS (1901-1979) was the first to formulate semiotics, the theory of signs, as an explicit and elaborated concept (1938). In modern terms semiotics can be defined as the scientific theory of the characterization, utilization and efficiency of **signs**

"MORRIS gave the following subdivision, which has become influential since the early days of analytical philosophy. Semiotics consists of:

- **syntactics**: the theory of relations between the signs
- **semantics**: the theory of the **relations** between the signs and the **objects** symbolized by them (**designata**)
- **pragmatics**: the theory of the relations between the signs and their users

"Furthermore, MORRIS made a distinction between general (or pure) semiotics as a neutral and fundamental theory, and descriptive semiotics- the latter term denotes the utilization of the theory to "concrete instances of signs", or, in other words, to a specific field of application" (2000, p. 155)

GERNERT observes that "descriptive semiotics covers a great variety of fields like linguistic semiotics, medical semiotics, architectural, musical, theatre and film semiotics, zoo semiotics, and phytosemiotics" (Ibid)

This is the bridge between syntactics and semantics

3015

SENESCENCE in complex systems^{1) - 4)}

H.T. ODUM states: "senescence is a property of the compact and **complex**" and adds that those: "Associations which have monolithic **structures**... develop senescence". Such **structures** "... do develop where power **flows** are highly concentrated" (1971, p.143-144).

As examples he gives crowded barnacle **growths** and overcluttered and dilapidated urban neighborhoods.

Senescent **complex systems** undergo destructive crisis which allows for their renovation or replacement.

It is however not clear how the concept (originated in **ecology**) could be applied to strongly **integrated systems**, as for example an individual living being.

3016

SENSIBILITY TO INITIAL CONDITIONS^{1) - 2)}

"The property of a system, or some K part of it in the **phase space** X such as if, starting from any initial position in K, **fluctuations** as small as wished end up generating macroscopic **divergences**" (after A. DOUADY, 1992, p.17).

RUELLE and TAKENS established that, in **chaotic systems** "two **trajectories** of the **attractor**, initially as close to each other as wanted, finally always diverge from each other. This **divergence** increases even, on average, exponentially with **time**".

..."Thus the **trajectory** actually followed by the system depends crucially from its starting point." (P BERGÉ, Y. POMEAU & C. VIDAL, 1984, p.111).

This is a basic difference between **stable** and **unstable systems**.

In conservative systems, the **trajectories** remain confined within closely determined **limits**, characterized by an **asymptotic attractor** or a **periodic** one (**stability** in the sense of LA-GRANGE). The **behavior** of such systems can be predicted.

However, they are not the rule, but well the exception. Conservative systems depends on no more than two initial and independent conditions, in which case a **chaotic behavior** cannot appear.

On the contrary, with three or more incommensurable initial conditions (or **degrees of freedom**, or **order parameters**), **chaos** appears, characterized by alternatively growing and contracting deformations of the **trajectories**, the deformations being limited by the most extreme values that can be taken by the physical **variables**. Thus, global **determinism** is not lost, but becomes concealed behind apparently incoherent **short term variations**. In a sense, the system seems to lose the precise "**memory**" of its past, retaining only a kind of statistical (or **ergodic**) "**memory**". This is related to the reciprocal influence of the various conditions on each other and to the impossibility of instantaneous transmission of their **effects**, at a distance. The global **determinism** does not wholly disappear, but at any instant, becomes locally fragmented and, due to **time lags** can never be fully recovered.

3017

SENSITIVITY^{1) - 2)}

The minimum **input** needed to produce an **output** in some **process**.

The **concept** is widely used in **simulation**, as for example in **Systems Dynamics**.

Sensitivity analysis aims at discovering how much the estimates used in a **model** can vary without impairing the **outputs** validity.

3018

SENSOR¹⁾

Any **element** or **subsystem** in a system which picks up some kind of **information**.

In natural systems, the sensors are, of course the sensorial **organs**, attuned to some specific kinds of **inputs** as for example visible light or sound waves.

We have learned however, to amplify considerably the range of our **perceptions** by creating numerous and very varied artificial devices that are able to pick up many **inputs** to which our biological sensors remain insensible, either because the possible effects are too weak or too small, or in inaccessible **ranges** (as for example herzian waves or X-rays).

These devices are equipped with appropriate optical, mechanical or electronic sensors.

P. CARIANI remembers that "In the late 1950's Gordon PASK constructed several electrochemical devices having emergent sensory capabilities. These **control systems** possessed the ability to adaptively construct their own sensors, thereby choosing the relationship between their **internal states** and the world at large... PASK's devices have far-reaching implications for **artificial intelligence**, self-constructing devices, theories of **observers** and epistemically-**autonomous agents**, theories of **functional emergence**, **machine creativity**, and the limits of contemporary **machine learning paradigms**" (1993, p.19).

It could be added that no **autopoietic system** can be conceived that should not have been able at its beginnings to construct its own **emerging self-organized** sensors.

3019

SENSORY MOTOR-LOOP¹⁾²⁾

The circular relation between motor **functions** and sensory apparatus that characterizes our interpretations of our **environment**.

H.von FOERSTER says: "In 1895 POINCARÉ was, I believe, the first to connect movement, or the change in position with the change in **perception**, and who said: "One interprets the other". that is, through my motor functions I interpret sensory **input**, and my sensory apparatus interpret motor inputs

" He adds that PIAGET found that in children "...their motor **activity** interprets their sensorium; that motoric changes their sensations; that a **relationship** exists between the **change** in body position and changes in sensation. the coupling of these two allows for the construction of what I claim to be the **object** (in German: "Gegenstand") the one that stands up against (again in German: "ent-gegensteht") (p. 21, 2002)

The sensory motorloop seems thus to be the necessary basic condition for any **constructivist** view.

3020

SEPARABILITY¹⁾

In most cases it is quite difficult to clearly separate a system from its **environment**.

Using the enterprise in its **environment** as an example, St. BEER states: "... these two systems are not absolutely separable, they do not have absolutely clear-cut **boundaries**. One of the reasons for the problem of separability is that each is influenced by a **set** of **coenetic variables** to be found in the world at large" (1968, p.391).

3021

SEPARABILITY AXIOM^{1) - 3)}

Any **operation** should be completely independent from the performing **operator**.

This axiom of disjunctive logic is the bedrock of the analytic **Cartesian method**.

Its validity is however growingly curtailed in modern science, since it is now evident that, in many (if not in all) cases, it is not possible to satisfy the separability condition.

The **operator** is most frequently an active **agent** in the **operation process**. It is merely acceptable to neglect his/her influence when he/she is only an **observer** whose influence is insignificant in **space** or **time dimensional domain**.

Systems science in particular needs a conjunctive logic. In J.C. LUGAN's words: "... the **organization**, the organized **object**, the **organization's** product and the organizer cannot be separated" (1993, p.91).

Examples abound, from the quantic to the **human systems level**.

3022

SEPARATRIX²⁾

The boundary between **basins of attraction**, i. e. between two zones of **stability** of different characteristics.

R.H. ABRAHAM and C.D. SHAW state: "By definition, separatrix points are not in **basins**. Thus, they belong to the insets of **limit sets** which are not **attractors**, the **exceptional limit sets**" (1987, p.549).

As a result, the separatrix corresponds to the critical **threshold**, the locus where **bifurcations** can take place.

As stated by St. KAUFFMAN, in two dimensions, the separatrix is a line (i.e. one-dimensional), and in three dimensions it is a surface (i.e. bi-dimensional) (1993, p.176-7).

3023

SEQUENCE (Evolutive)^{1) - 5)}

The successive **states** of an **ecosystems transformation** after a **disturbance**.

S. REICE states: "**Disturbance** is a reinitializing step in the successional development of a **community**. Different **disturbances** remove different species to different degrees. Therefore, the particular **response** of the **community** is likely to be a unique successional sequence" (1994, p.428).

In global economic or social **communities**, the same rule is applicable as to the removal of some systems and their subsequent replacement or reappearance.

3024

SEQUENCE (Life)¹⁾

The successive **states** of a system from its beginning or birth to its final dissolution.

Very different types of systems show quite similar life sequences.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

When a new system or type of system appears it starts to grow or multiply slowly. However the **growth process** generally gathers momentum, accelerating until some kind of **negative feedback** appears, which first decelerates **growth** and later on stops it completely.

Thereafter, the system enters in its maturing phase and becomes **homeostatic** (or acquires **dynamic stability**) and starts to fluctuate between a lower and an upper **limit of stability**.

After a more or less long time, the system loses its adaptative capacity (generally rather suddenly) and since it is not anymore able to maintain itself, its **elements** escape from its **control** and the system disappears or dies.

These life sequences have been observed in very diverse settings, as for example:

- in individual living beings
- in animal and vegetal species
- in the production of ecological systems
- in business or industrial firms
- in economic sectors
- in political systems

(See for example F. MEYER in his "Problématique de l'Evolution" (1954) or Howard T. ODUM's "Systems Ecology: an Introduction" (1983).

The life sequence can be explained in the following way, at least in general terms:

1. The new system has a significant potential for innovation, due to its new combination of **information** (genetical or technological for example).
2. However, it must first learn and adapt to its **environment**. Thus its beginnings are slow and sometimes difficult. In some cases it must undergo wide restructuration during this period.
3. When sufficiently trained or adapted, it becomes able to develop its potential for **growth**. If it is really innovative, it will find for itself an important **niche** in its **environment**, many times at expenses of older systems.
4. After a period of nearly unfettered **growth** it starts to meet a growing resistance, from older competitive systems which try to regain ground, from new ones which enter the **field**, or even because of its own **activity**, as for example saturating its **environment** with its products or **waste**.
5. Finally these limiting factors overwhelm its drive and **growth** stops. The system is now well adapted and pass through a succession of up and downs due to temporary rekindling of its innovative capacity and, on the other side, bouts of sluggish routine or resistance in its **environment**.
6. The system's basic potential is finally spent and it loses **adaptability** to its **environment** and, even **control** over its own **elements** and **subsystems**, becoming thus exposed to a final destructive crisis.

3025

SERENDIPITY¹⁾

The faculty of making fortunate and unexpected discoveries by accident.

The term originates in the fairy tale "The three Princes of Serendip" (H. WALPOLE). It is now quite generally accepted in the forementioned meaning, since it covers a kind of very relevant mental activity. Indeed, in numerous instances quite important discoveries have been made in a seemingly sudden flash of illumination, which probably corresponds to a not yet clearly understood cerebral **process**, through unplanned and automatic neural **interconnections**. Of course, serendipity visits only well informed, open, inquiring and creative minds, who are able to *notice* the deep significance of some seemingly fortuitous **event**. (FLEMING discovery of penicillin, by *observing* a "spoiled" bacterial culture and inquiring for the cause of this unforeseen outcome). It is somehow akin to the "Eureka" syndrome and to the proper **perception** of unsuspected systemic **interrelations**.

→ **Clue, Effects (Side); Random phenomenon; Relevance**

3026

SERIALITY²⁾

The **relation** which is **transitive, asymmetrical** and **connected**. **Aseriality** is the absence of any of these **relations** (J. FIBLEMAN & J. FRIEND, 1969, p.33)

FEIBLEMAN and FRIEND give as an example of a serial **relation**: "the enclosure of apple seeds by flesh and of flesh by skin is a serial **relation**" On the contrary the **relations** between grains of sand "are aserial, since they lack **asymmetry**" (Ibid).

3027

SERVO-MECHANISM⁵⁾

A device that consists of a **sensor**, an **amplifier** and a **motor** and is used to maintain the steadiness of the mechanical device of which it is a **part**.

A servo-mechanism is in fact a 2nd level feedback applied in specific ways in accordance with the permanent nature and **function** of the regulated system

The servo-mechanisms are needed to regulate the regulating (or **control**) subsystem's **variables** in order to adapt them to the changing **environmental** conditions.

J. MILSUM writes: "... the **output** is required to follow or "track" slavishly an often-varying desired, reference or command **input**" (1968, p.43).

Examples are " ... power steering of cars,... or neuro-muscular systems used for positioning of limbs, eyes, etc." (Ibid, p.42).

The study of servo-mechanisms is interesting in relation to the **behavior** of **living systems**. According to G. SOMMERHOFF: "...since many servo-mechanisms produce some type of **goal-directed behavior** it is not surprising that some of the general concepts of servo theory can illuminate parallel forms of **goal-directed behavior in living systems** – concepts like **error control** and **feedback loops**, for instance. But there are many limits to this. The **goal** of the **activity** of a servo-mechanism is set by an **external** command. This **command** provides the reference **signal** from which the error **signals** are derived to which the **feedback** mechanism responds with the necessary corrections" (1969, p.153). Moreover, as noticed also by SOMMERHOFF, in biological (and social?) systems, the **commands** are integrated in a **hierarchy** of oriented **behaviors**. And still: "...the concept of **error signal** is also beset with difficulties... in such **goal-directed processes** as embryonic **growth**, maturation, **learning**, **evolution**, etc... – or even in such simple cases as a rat taking the correct turning at a **choice** point of a maze" (Ibid.).

3028

SET²⁾

A collection or **class** of perfectly differentiable **elements**, which is considered as a **whole**.

Sets are usually represented by letters, while their **relations** are represented by connecting **symbols**.

A set can be:

- **finite**, if it contains a finite number of **elements**;
- **infinite**, if it contains an infinite number of **elements**;
- **ordered**, if each **element** occupies a well defined place;
- **null**, if it does not contain any **element**

The set of all **elements** taken in account is the universal set, or **universe**.

Any set has a complement, i.e. the set which contains all the **elements** not belonging to the former one.

A **subset** is a set included within another one.

Sets may overlap, i.e. have at least one common **element**. On the contrary, sets without any common **elements** are disjoint sets.

Operations on sets are described by G. BOOLE's binary algebra. The well known **VENN diagrams** are geometric **representations** of sets. These **representations** have been recently generalized by A. EDWARDS (1989).

3029

SET THEORY in systemics^{1) – 2)}

Systems are more than sets. R. ROSEN observed that: "Most of the difficulties of "**General System Theory**" have arisen from a confusion between systemhood and set-ness; the at-

tempt to treat those properties of a particular system which depends on its systemhood as if it were simply a part of the Theory of Sets" (1991c, p.214).

This is related to the difference between cardinality and order relations.

→ **Logical types; Theory of types**

3030

SHANNON LIMIT⁵⁾

The theoretical limit for how much **information** a **communication channel** can carry.

Information is taken here in a strictly quantitative **meaning**.

It refers to the efficiency of a broadcast system in terms of the number of **bits** of information per second that it is possible to send, for ex. per herz in a radio bandwidth.

3031

SHIFTING (or SWITCHING) CAPACITY^{1) - 2)}

The possibility for a system to modify its internal links at least up to a certain point.

W.R. ASHBY states: "A system whose **variables** can be sometimes fluctuating and sometimes constant is adequately equipped for switching" (1960, p.167).

This implies that only some points of the interconnection **nets** is active at any moment as, again, stated by ASHBY: "Any system with a 'switching' **process** must use... an alterable **distribution** of constancies" (Ibid.).

This is specially important for systems whose **communication network** is of paramount importance, as for example a telephone system and, generally, **neural networks**, natural or artificial.

Parts of the **network** which are not linked become for some time independent, but altogether, inactive.

3032

SHOAL

→ **Boids; School; Squeezing effect**

3033

SIGMOID²⁾

"A function that has a low, shallow slope initially, followed by a steeper rise that gives way to another shallow slope" (M. CAUDILL, 1992, p.15)

The author comments: "Its value always increases as its **input** increases, yet at the same time it is bounded by minimum and maximum values" (Ibid.).

The sigmoid is characteristic of the **logistic** equation. It reflects a growing **dominance** of some **negative feedback** in the **process**.

3034

SIGN^{1) - 3)}

Any **event** registered by an **observer**.

Signs are necessarily **percepts**, visual, auditive, tactile, etc. They imply **abstraction** (PEIRCE's "abstractive **observation**"), **distinction**, **frames of reference**, **learning**, **memory**, **observation**, **representation**, etc...

There are numerous different viewpoint about signs, more or less complementary and compatible. The given definition is very general, but admittedly somewhat simplistic.

F. FRISCHNECHT and J.P.van GIGCH give a different definition: "Signs are **symbol tokens** or **symbol carriers**" (1989, p.241). The **tokens** or carriers are **events** and only **observers**, mostly humans, are able to understand them as **symbols**. The **observer** needs thus to possess a **repertory of significances** if he/she is to interpret the sign. If this condition is fulfilled, the sign becomes an **information element**. G. KLAUS writes: "As significance bearer, the sign possesses a **structure**" (1976, p.915). It is the **perception** of this **structure** that generates the **information**.

C.S. PEIRCE considered that the most perfect signs are those which carry about equal symbolic, iconic and indicative loads.

Following C.S. PEIRCE, F.Y. SEIF explains: "A **semiotic** sign is an indivisible **triadic structure**: sign (or what PEIRCE calls a "representamen"), **object**, and interpretant. Anything is a sign if it represents an **object** and determines an interpretant. The term "**object**", although empirical, is not necessarily a material thing" (1992, p.810). A good example could be the "cross" in the Christian religion.

SEIF reckons however that: "While this **structure** is inadequate for the **dynamics** of physical or metaphysical **phenomena**, it nevertheless represents an **image** of a **frozen** moment in the **semiotic process**" (Ibid.).

Any sign may affect the **behavior** of the **observer**, provide he/she is able to recognize it some significance, or even possibly its lack of significance (being disconcerted or scared by something registered, but not interpreted).

Ch. MORRIS (quoted by R.L. ACKOFF and F.E. EMERY) "... discusses three types of **signification** (**semantic** properties) of signs and three corresponding 'dispositions to react in a certain way' (pragmatic properties). **Semantically** speaking a sign, for MORRIS is:

1. *Designative*, "insofar as it signifies observable properties of the **environment** or the actor, (as black)"

2. *Prescriptive*, "insofar as it signifies how the **object** or **situation** is to be reacted to so as to satisfy the governing impulse, (as ought)"

3. *Appraisive*, "insofar as it signifies the conformatory properties of some **object** or **situation**, (as good)".

"The corresponding (pragmatic) **functions** are to produce:

1. "A disposition to react to the designated **object** as if it had certain observable properties"

2. "A disposition to act in a certain kind of way to the designated **object** or **situation**"

3. "A disposition to act toward a designated **object** as if it would be satisfying or unsatisfying" (1972, p.171).

Still another classification of signs is proposed by A. CORNELIS:

"**Natural sign**: An undifferentiated mixture of **meaning content** and **meaning carrier**. Natural signs are dominated by emotive **meanings**. Thus for example the **meaning** of the mother for the child illustrates a natural sign... (It is) the emotional layer build up with the help of natural signs (that) makes possible the construction of a basic **knowledge** system..."

"**Linguistic sign**... as it has been defined by de SAUSSURE. First de SAUSSURE stresses the **distinction** between **meaning content** and **meaning carrier**. Second de SAUSSURE defines the **relationship** between **content** and carrier as arbitrary..."

"**Abstract sign**: An abstract sign has the logical characteristic of abandoning any arbitrary or natural **relationship** between **meaning content** and **meaning carrier**. This **process of abstraction** is characteristic for scientific thought and more generally for... the scientization of **culture**. **Meaning contents** and **meaning carriers** are not longer organized by their interrelationship - either natural or conventional - instead they develop into two different systems, of **identity** on one side, and **structure** on the other side" (1986, p.141-2).

Shortly, a sign tends to produce (more) **information**, **learning** (or training) and motivation.

Signs may have a more or less embracing, i.e. systemic, implicit **significance**, that may be differently perceived by different **observers**. They may be more or less efficient from a **semantic** viewpoint, according to what **significance** the **receiver** is able to give them. As observed by U. ECO: "... the labor of sign production also represents a form of social criticism and of social practice, a sort of ghostly presence" (1979, p.314). All **cultures** have their own, slightly different ways, to construct signs and individual interpreters are largely subservient to this global **process**. See for instance MARUYAMA's **mindscapes**.

Signs can also be **ambiguous**, for example in poetry or painting, presenting a great number of possible connotations (M.C. ESCHER's engravings are a notorious example).

A very significant historical study and comparative critical evaluation of the notion of **sign**, made by N. LUHMANN was reproduced in the Journal "Cybernetics and Human Knowing" 6 (3) p. 21-27.

This work intended "to combine systems theory with sign theory by trying to integrate G. SPENCER BROWN's "**Laws of Form**" (N. ORT and P. MARKUS, 1999, p. 39-46)

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

3035

SIGN AND SYMBOL ³⁾

While a sign is simply something which *may* carry a **meaning** for some definite **observers** with the needed background, a symbol is a "something that represent something else by association, resemblance or convention..." (AMERICAN HERITAGE DICTIONARY, p.1302).

According to C.S. PEIRCE: "A sign is either an **icon**, an index or a **symbol**. An **icon** is a sign which would possess the character which renders it significant, even though its **object** has no existence; such as a lead-pencil streak representing a geometric line. An index is a sign which would, at once, lose the character which makes it a sign if its **object** were removed, but could not lose that character if there were no interpretant. Such for instance, is a piece of mould with a bullet-hole in it, as sign of a shot; for without the shot there would have been no hole; but there is a hole there, whether anybody has the sense to attribute it to a shot or not. A **symbol** is a sign which would lose the character which renders it as sign if there were no interpretant. Such is any utterance of speech which signifies what it does only by virtue of its being understood to have that **signification**" (in J. HOOPES, 1991, p.239-40).

D. Mac KAY gives other examples: "An overcast sky "means" that rain is imminent." (1969, p.88) This is just an observed **situation**, which need not necessarily and is not intended to exert a preselected influence on the **observer** and induce him to some specific **behavior**.

On the contrary, when **learning** the national anthem, anyone is supposed to adopt a dignified and at times quite precisely, specified attitude because the anthem is a symbol of the mother country to be respected and honored.

In short, signs nature, **perception** and use are an unavoidable bedrock for systemics. This explains the precursor role of linguists, semioticians and semanticists in systemics.

3036

SIGNAL ^{1) - 3)}

"A string or strings of **energy** and **matter** in transit between a **transmitter** and a **receiver**" (T.F.S. ALLEN & T.B. STARR, 1982, p.277).

According to ALLEN and STARR, "Its **meaning** is undefined" (Ibid).

This is so, at least, until we use a physical **code** (acoustic, electromagnetic, etc...) and/or a semantic one, shared by the sender and the **receiver**, thus endowing the signal with a **meaning**.

3037

SIGNAL (Binary) ²⁾

A signal emitted by a device that can produce only two significant **states**.

Binary signals serve to modelize binary relations, whose algebra was constructed by G. BOOLE in 1854 (1952).

The most obvious example is 0 and 1, both signals easily produced electronically, which correspond to any kind of dual oppositions: yes – no; positive – negative; false – true; existent – non existent; etc...

3038

SIGNAL (Iconic) ^{1) - 3)}

G. BATESON gives the following example of iconic signal: "The bared fang at a given instant may *mention* an attack which, if and when it occurs, will include a *new* baring of the fangs" (1973, p.393).

This supposes that the **receiver** is able to understand what he perceives with its correct **meaning** within a formerly learned **context**, i.e., any signal supposes common understanding of a shared **coded context**.

3039

SIGNALS (Discrete or continuous) ²⁾

G. PASK discusses the different characteristics of discrete or continuous signals.

He observes: "Discrete signals carry with them greater assurance, for the instrument (Note: i.e. the detector) only needs to decide which one of a few signals occurred" (1961a, p.125).

This is the reason for the generalized use of **digital codes** in place of **analogical** ones.

As stated by PASK: "Generally, the discrete signals leave less uncertainty about their source than continuous signals both for **organisms** and **machines**". Even so, "Various **coding** schemes, more or less efficient, more or less fallible can be used; for example, in a discrete system the intervals between individual pips may or may not be a signal and able to convey **information**" (Ibid).

As an example of continuous signal, PASK offers "...the concentration of a specific chemical hormone in the bloodstream" (Ibid).

Continuous signals seem best adapted for the **regulation** of systems oscillating within a **stability** zone limited by some **thresholds**, i.e. **homeostatic systems**.

3040

SIGNALS (Forerunner)

→ Forerunner signals

3041

SIGNIFICANCE/SIGNIFICATION

→ Meaning

3042

SIMILARITY ¹⁾

A likeness between systems **structures** and/or **processes**.

The concept of similarity is quite elusive. It is not merely an **analogy**, in a **metaphorical** sense, but the clear recognition of an **homomorphism**. Similarity is *observed*. This means, in A KOESTLER's words, that it "involves **processes** of **abstraction** and generalization in the nervous system which are largely unexplained" (1964, p.201).

To become more than an **analogy**, similarity must be described in **topological** (i.e. graphical) or mathematical terms. KOESTLER, for instance, speaks of "**bisociation** of conceptual **matrixes**", which implies a kind of **mapping**, or **pattern-matching**.

Recognizing similarities is a highly creative mental **process**, typically systemic. It produces at times amazing results, as for example when A. WEGENER introduced the idea of continental drift, conducive to plate tectonics, having observed geographical complementary similarities in the forms of continents.

The observation of some **dissimilarities**, on a background of similarities, can be just as productive, as shown by DARWIN's Galapagos finches.

"Similitude" is a synonym unfrequently used.

→ Self-similarity

3043

SIMPLEXITY ²⁾

"The **emergence** of large-scale simplicities as a direct consequence of **rules**" (J. COHEN & I. STEWART, 1994)

Simplicity can be considered as a near-synonym for S. KAUFFMAN's "**antichaos**".

M. SHERMER comments: "These predictable **laws** (of nature) interact with unpredictable **contingencies** to occasionally trigger the "**collapse** of **chaos**". After the **collapse** simple **rules** "emerge from underlying **disorder** and **complexity**" (1997, p.25)

The whole subject seems to be closely related with the disordering of systems of lesser **levels** by excessive **energy inputs**, the appearance of growing and unwieldy **fluctuations**, the crossing of a **critical point**, and the **emergence** of a more complex system around a new **nucleus**, as described in Prigoginian **thermodynamics of systems far from equilibrium**.

3044

SIMPLICITY ¹⁾

Character of a **process** or system which can be described through a quite limited number of **operations**.

H. SIMON shows how **apparent complexity** in our **models** results many times of our lack of **understanding** of the underlying simplicity of **relationships**. He gives as an example the simplification of the Ptolemaic cosmological **model** by COPERNIC, KEPLER and NEWTON (1990, p.129). This could however be a case of

"Seek simplicity, but distrust it". In effect more than two centuries later, POINCARÉ demonstrated that, while correct in principle and in general, classical cosmology could not explain some anomalies in planetary orbits, a result that led later on to the discovery of **chaos**.

→ "Self-similarity".

3045

SIMPLICITY (Organized) ¹⁾

The character of the deterministic motion of a single, or two interacting moving **elements**, or more generally of the interplay of two or three **variables** at most.

W. WEAVER (1948) coined three expressions to differentiate simplicity and complexity:

- Organized simplicity, simple, **deterministic**;
- Disorganized **complexity**, complex, **random**;
- Organized **complexity**, **self-organizing**, **ergodic**, **chaotic**.

Classical science, until the last decades of the 19th Century, based on **deterministic models**, discovered and explored organized simplicity, as for example in mechanics, optics or acoustics.

Disorganized **complexity** was then tackled by the newly introduced statistical **methods**, as for example in **thermodynamics**.

Organized **complexity** became under investigation only in the 20th Century and its study is still in full development.

3046

SIMPLICITY (Principle of maximum) ²⁾

"The **structure** of the **organism** is determined as the simplest possible physical **design** which can perform the necessary **function** with the required intensity" (N. RASHEVSKY, 1960, p.125).

It is originally a biophysical principle. It is however clear that it applies (or should apply!) to **organizations** in general, but specially to the most complex ones.

RASHEVSKY observes that the biophysicist D. COHN proposed the expression, more precise according to him, of "Principle of optimum **design**". Considering that the word "optimum" implies the necessity of establishing a **criterion** of such "optimality", the advantage is not evident.

3047

SIMPLIFICATION ¹⁾

As a **set of methodologies** to study "organized **complexity**" (W. WEAVER, 1953), systemics and cybernetics have introduced new **modes** of simplification.

Some interesting examples, among others, are:

- J.G. MILLER's general principles of **organization of living systems**

- H. SIMON's **hierarchies of subsystems and modes of decomposability of complex systems**
- G. KLIR's **Reconstructability Analysis**
- J. WARFIELD's **Interpretive Structural Modeling**
- H. HAKEN's **Synergetics**
- H. SABELLI's general **Process Theory**
- D. Mc NEIL's general **Toroid model**

In general these **methods** aim at identifying coherent complex units within more global **wholes**. As jokingly stated by J.L. LE MOIGNE, a system should not be sliced as a sausage.

G. KLIR defines a "*basic simplification principle*": "A sound simplification of a system should minimize the loss of relevant **information** with respect to the required reduction of its **complexity**". He adds: "Among all comparable simplifications of the given system, we accept only those with minimum **uncertainty**" (1991, p.401).

Even such complex **transformations** as the **ergodic** or **chaotic** ones, are made more intelligible by **models** whose systemic character is evermore widely recognized.

3048

SIMULATION ^{1) - 2)}

"The **representation** of a system to study its **component parts** and their **relationships** in terms of variable **inputs** and **outputs**".

Or "**Representation** of natural and **social systems** or **processes** by devices or **models** that imitate the **behavior** of the systems or **processes**" (UNESCO-UNE, 1983, p.14).

A.G. BARTO describe simulation as follows: "The **method** used to find the **model's** global **behavior** base of **knowledge** of an **initial condition** and the locally acting **constraints**" (1991, p.388).

As observed by F. FRISCHKNECHT and J.P. van GIGCH, simulation is basically the creation of an equivalence **relation** between **objects** and adequate **symbols** (1989, p.243). This is the deeper **meaning** of "**representation**". *Adequate symbols* must be at least **homomorphic**. As to "**objects**", they are normally complex, i.e. include internal **relationships** and, when useful, external **connections**.

Simulation **models** are necessarily dynamic.

"If... a computer is used to generate the **model's behavior**, we call the **process** computational simulation" (A.G. BARTO, Ibid). This author discusses simulation either by **continuous**, or **discrete models**. However, whatever the **method** used, the real value of simulation depends on a correct **understanding** (in relation to the **goals** of the **operator**) of the system to be modelled and the nature of the significant **data** to be obtained; of the satisfactory **homomorphism** between the conceptual **model** and those characteristics of the system to be mod-

elled and, finally of the adequate translation to the computer **model**. If these different conditions are not fulfilled, the well known motto "Garbage in, garbage out" defines the results.

The quality of the results depends, of course of the **fitness** of the **model**, i.e. of the validity of the criteria used for its construction, irrespective of the simulation **technique** applied. In M. SHUBIK's words: "... once the **model** has been formalized, the insights and errors of its builder will be reflected without question by the simulation" (1967, p. 151).

In any type of simulation, the user of the results to be obtained must remain interactive with the investigator in charge, in order to maintain the **relevance** of the simulation in relation to the concrete **situation**.

The main techniques in use are **analog** and **digital**. An important variant is **aleatory simulation** ("Monte Carlo" method), which introduces **constructed randomness** in the **model**.

Simulation is generally aimed at **prediction** of the **behavior** of the simulated **process** or system. For a number of practical and conceptual reasons, the results can however never be fully guaranteed.

Apart of **prediction** R. AXELROD also states the following uses of simulation (1997, p.16-17):

- Performing certain tasks using **artificial intelligence**, as for example "...medical diagnosis, speech recognition and **function optimization**..." and "... simulations of task **environments** can also help design new techniques"
- **Training**: "...Flight simulators for pilots is an important example of the use of simulation for training"
- Entertainment: as for example "... simulations of completely imaginary worlds"
- **Education**: "... The primary use of simulation in **education** is to allow users to learn **relationships** and principles for themselves"
- Proof: ... "CONWAY's **Game of Life** demonstrates that extremely complex **behavior** can result from very simple **rules**"
- Discovery: ... "Using simulation for prediction can help **validate** or improve the **model** upon which the simulation is based... and for the discovery of new **relationships** and principles..."

3049

SIMULATION (Analog) ²⁾

A simulation of a **concrete process** or **network** through a mechanical, hydraulic or electrical **model**, whose **behavior** is considered equivalent.

H.T. ODUM writes: "Analog simulation has many purposes. The **process** of setting up **flows** and functional **parts** is a powerful stimulant to the imagination, helping one to be precise, to ask new questions about the particular **networks**, and to secure the right **measure-**

¹⁾general information

²⁾methodology or model

³⁾epistemology, ontology and semantics

⁴⁾human sciences

⁵⁾discipline oriented

ments. The electric **flows**, being very fast, can simulate much slower systems. Because electrons and their control pieces are very small, they can model large systems that would be expensive or impossible to manipulate experimentally" (1971, p.258).

ODUM gives the simulation of the **flows** of groundwater across the state of Nebraska as an example and states: "The flow of electrons in wires is so fast that fifty years of changes can be observed in a short **time**" (Ibid).

3050

SIMULATION MODELS (Taxonomy of) ^{1) - 2)}

H. PRAEHOFER resumes as follows T. ÖREN's taxonomy of models "... for which he uses the following classification criteria: **time set** of the model, **trajectory** of descriptive **variables**, existence and range of **variables**, functional relations of **variables**, spatial **distribution**, **organization** of **component models**, and **goals** to be pursued...

"According to the criteria **time**, we speak of **continuous-time** models when **time** is represented by real numbers and we speak of **discrete-time** models when **time** is represented by integers or a **set isomorphic** to the integers. According to the second criteria, we speak of **continuous change** models when **state changes** occur continuously over **time** and we speak of **discrete-change** models when they occur in **discrete** jumps. Pairwise combinations of one category for each criteria define well-known modeling concepts. **Continuous-time** and **continuous-change** models are differential equations specified models, **discrete-time** and **continuous-change** models are difference equation specified models, **discrete-time** and **discrete-change** models are **automaton** models, and **discrete-change** and **continuous-time** models represent the class of **discrete event** models".

Practically: "The real system is regarded to be nothing more than a source of **data**. The model is a **set** of instructions capable of generating such **data** and the computer is a means of carrying out these instructions to generate such **data**."

"A direct relation exists between the real system and the model and is summarized by the term **modeling**. A direct relation between the model and the computer exists and this relation can be denoted as **simulation**" (1991, p.287-289)

3051

SIMULATION (Modes of) ²⁾

The French systemist B. WALLISER distinguishes the following **modes** (1977, p.183-5):

Analogic: a simulation mode consisting in using a mechanical, hydraulic or electronic device whose functional **behavior** is equivalent to the system's one.

Digital: a mode using a numerical **model**, generally analytical, and which can be translated into a **computer program**.

Deterministic: a mode considering **variables** and **interactions** as perfectly determined, producing unique **output** values as a **function** of **inputs**.

Operative: a mode consisting in working on the real system, or some similar **concrete system** in "laboratory conditions".

Random: a mode introducing **randomness**, i.e. putting the **variables behavior** under the influence of a **random** procedure ("Monte Carlo" method for example).

The value of the results depends of course on the hypotheses used and the **model's** limitations.

3052

SIMULATION (Systemic) ^{1) - 2)}

Systemic simulation implies very difficult problems. It has to reproduce in a satisfactory way the **nonlinear** character of the **complex system** to be modelled (once well and clearly defined in relation to the modelizer aims) and their possible **chaotic behavior**.

There seems to be still much ground to cover in order to complete a good theory of such simulation.

H. PRAEHOFER states: "Through the **complexity** of real systems, a fully comprehensive **model** of a real system is infeasible to build." (1991, p.300, quoting B. ZEIGLER). He adds: "**Modeling** always means idealization, **abstraction**, and **simplification**. Only some aspects, the aspects of the real system relevant for the **objectives** in hand, may be incorporated into the **model**" (Ibid).

Until now the best systemic **modelization methodology** seems to be ZEIGLER's "Multifaceted **modeling methodology** whose central concept is the "**system entity structure**" (1994, p.169-178).

3053

SIMULTANEITY ¹⁾

F. HEYLIGHEN points out that in **relativistic** theories "the **relationship** of simultaneity becomes relative (i.e. dependent on the reference frame of the **observer**") (1990a, p. 438).

This can be generalized.

Due to variable **time lags**, in no type of **transmission process** is **transmission** instantaneous. Thus simultaneous **events** in different **parts** of a system remain unconnected for some **time**.

Event A and **event B** can influence each other only after a **delay** and only if and when some of their consequences meet and interact in some place. So, in any **complex system**, somewhat disconnected areas of **activity** do

always exist: simultaneous causes do not generally produce simultaneous **effects** in the system as a **whole**.

This is the basic cause of **nonlinearity** and **chaos**.

3054

SIMULTANEITY: the relativist view ^{1) - 3)}

F. HEYLIGHEN writes: "In **relativity** theory, we have the principle of **relativity** together with the principle of invariant speed limit **c** for **causal propagation**, which entail the impossibility to distinguish **simultaneous** from non-simultaneous **events** that are spatially separated" (1990a, p.441).

This is the case, for instance, of somebody observing the sky at night. The simultaneous character of the observed celestial show is a perceptive **artefact**.

HEYLIGHEN views this principle as an example expressing "the impossibility to establish a certain classical **distinction** in an absolute way" (Ibid).

R. FISCHER states, in a different sense: "... the **covariance** between the "external motions" of substance "out there", and "internal motions" (the **subject's** systemic rate of **change** as a reflection of his/her arousal) that results in **invariant** features of the **transform** (**interface** or reality) is a principle of *neurobiological relativity*" (1991, p.99).

3055

SIMULTANEOUS EFFECTS ^{1) - 3)}

Simultaneous **perception** by neurons is not absolute.

J.von NEUMANN writes: "...Wherever "simultaneity" is mentioned in the above (note: i.e. in nerve stimulation), it cannot and does not mean actual, exact simultaneity. In each case there is a finite period of grace, a **summation time**, such that two pulses arriving within such a **time period** still act as if they had been simultaneous. Actually, things may even be more complicated than this – the **summation time** may not be a sharp concept. Even after a slightly longer **time**, the previous pulse may still be summed to the subsequent one, to a gradually decreasing, partial extent" (1958, p.55-56).

Perfect simultaneity thus seems to be still one more abstract concept, which conceals a practical observational impossibility, even at the **receivers** end.

3056

SINGULARITY ^{1) - 2)}

"Specific locus where a radical **transformation** takes place, called **bifurcation** by mathematicians" (C. BRUTER, 1989, p.438).

A singularity is in most cases the result of a repetitive **positive** and non compensated **feedback** bringing about an accelerating **accumulation**; it is an exceptional **phenomenon**. The

function or system thus reaches a **runaway** "point of no return", or **threshold**, locus and moment of sudden **discontinuity**, or **catastrophe**, which may destroy the system or trigger a deep structural and functional **transformation**, corresponding to a **bifurcation**.

The singularity is necessarily the result of a dynamic **process**, leading to an "extremality".

Cl. BRUTER states that "... the most interesting and significant **phenomena** in our universe are those of genesis or end of things ("generatio" and "corruptio")" (Ibid).

He adds: "We must note, in case of a singularity, the increase of the potential capacity for **evolution**... In any common point, the direction and value of **growth** are fixed" (NOTE: in mathematical terms, the **function** representative of the **process** is **continuous** and derivable) "At the singularity point, we are in an expecting **situation**. Crossing this point, there will be **growth** or decrease" (Ibid., p.441).

BRUTER enumerates as follows the basic physical properties of singularities:

"By its **extremality's** properties, a singularity is **visible**.

"By its **uncommon** character, it is **valuable**: the spatio-temporal **costs** of its making is high

"By the specific geometry in its **vicinity**, it plays the role of an **organizing center** around itself, as well structurally as functionally, due to the fact that the local **transformation** potential is generally higher than at regular points" (Ibid).

Insects molting or a revolutionary **change** of political regime are examples of singularities.

→ "**Nucleation mechanism; Nucleation principle**".

3057

SINGULARITY (Bifurcation) ^{1) - 2)}

Cl BRUTER describes its two principal properties as follows:

"Bifurcation appear for values of the bifurcation **variables** forming void measures sets in the **variables space** of the bifurcation." (1989, p.449)

Bifurcation singularities are very unusual situations!

"For these singular values, mathematical objects show degenerated forms."

"All this corresponds to very understandable physical situations. If the **structure** of any **object** is to be modified, it must first pass through a dissolution phase of the initial **structure**, at least, partly".

"This phase is only transitory, in view that the **object** looses its immediate qualities of **stability**" (Ibid).

BRUTER cites the example of insects metamorphosis, in which "...the chrysalid's formation leads to the practical dissolution of all the organic systems... quickly followed by a assembling phase in which the organic systems of the adult insect are elaborated from special embryonic **cells**." (Following DENTON: 1988)

3058

SINK ¹⁾

A fixed point that acts as an **attractor** for all points in its **neighborhood**.

There is no escape from a sink.

2. A place in the **environment** of a system which receives **waste** from the system.

Different types of **waste** go to different types of sinks, which receive either material (rubbish dumps of many different types) or energetic **waste** (f. ex. the atmosphere, as receptor of heat, i.e. degraded **energy**).

As the use of materials and **energy** is growing exponentially, the problem of sinks is growing at the same pace. This introduces the need for reusing as much as possible all kind of **waste** as **sources** of useful **resources**, i.e. the need for **recycling**.

Recently, we also started to create **information** sinks, by accelerated **accumulation** of unused (or unusable) **data** and premature invalidation of techniques. This will probably become a very serious problem in a near future.

3059

SITUATION ¹⁾

"Some **state** of the world at a given instant, focused from the **viewpoint** of some definition of a system" (M. LIU.1990, p. 40).

According to LIU we look for "...a **representation** of the world from a selected **viewpoint** and in relation to a predefined study objective. We prefer the term "situation" to the one of "state", in view that this latter one tends to be restricted to the **description** of the inside of the system, while a "situation" describes the system, its **boundaries** and its **environment**" (Ibid).

Of course, neither the "state", nor the "situation" can ever completely be described.

What we call a situation is merely the imperfect result of a set of simultaneous or nearly simultaneous **perceptions**, associated in a manner as coherent as possible, and to which an **observer** is able to give a global **meaning**.

A situation relates generally to the instantaneous **state** of a complex **entity**. R. ESPEJO stresses that: "... the **complexity** of the situation is defined by the number of non-equivalent outcomes recognized by the **viewpoint** in the situation" (1988, p.140). The **viewpoint** may be individual or shared through constructed **consensus** among various **observers**. In any case: "Individuals only see 'sides of a situation', never the **whole** of it; indeed there is no **viewpoint** that can capture in full the **variety** of a situation... not least because human activities are constantly being created and recreated by the people participating in it" (Ibid, p.139).

Moreover, a situation is only a fleeting **event** in a chain of **events**.

The **observation** of successive situations allows to perceive a system or a **process** in course of **transformation**.

However, the **coherence** that may be perceived in the situation also depends on the previous **knowledge** by the **observer** of the **constraints** prevailing in the observed **universe**. This **knowledge** may be insufficient, for example because of the lack of historical **data**, or the inexistence of some means of **observation**, or due to some prejudices.

In these (very general) cases, the situation is partly "**invisible**" in G.de ZEEUW's sense (1992), and the **observer** may be led to a false **evaluation** and thus induced to commit mistakes. In St. BEER words: "He is playing a **game** of incomplete **information**" (1968, p.279).

According to R. ESPEJO: "...The **complexity** of the situation is defined by the number of non-equivalent outcomes recognized in the situation by the **viewpoint**" (1988, p.140). ... or by the different **viewpoints** of the participating **observers** during a period of **time**.

J. WARFIELD, inspired by G. VICKERS, recommends the use of the term "situation" in "replacement for the more commonly-used "**problem**", because: "It has been frequently observed that a **problem** is, invariably, a human **construct** not subject to **observation**. A situation, on the other hand, is at least partly observable, if not fully so. Inherently, it is dynamic, changing with **time**, and its **observation** is not limited to any one individual. On the contrary, because it is often distributed in **space** and **time**, **observation** by various **observers** is often essential to its **understanding**. Moreover this term keeps the door open to exploration, while **problems** often harden into too-narrowly-defined **frames of reference**" (1990, p.9).

3060

SITUATION COMPLEXITY INDEX ²⁾

J. WARFIELD proposes the following **criteria** to judge the **complexity** of a situation:

"Necessary and sufficient conditions that a situation be **complex** are that the situation maintains seven **components**: a) human presence, b) a generic **purpose** associated with human presence, c) exercise of **system inquiry** by the human presence, d) human purpose-related **infrastructure** to make possible the **system inquiry**, e) system-related **environment**, f) sensing apertures for **space-time** sampling of the situation by the human presence, and g) **cognition** on the part of the human presence" (1995, p.31).

This is a quantitative index, whose practical use is explained by WARFIELD (p.32).

3061

SITUATIONS (Large scale)^{1) - 4)}

"Situations that engulf large number of people and **artifacts** in hazardous **networks** of **interdependence**".

J. WARFIELD, who gives this definition, adds: "To allow such situations to be designed irresponsibly or to permit final **decisions** that unleash horror upon tens of thousands is not conducive to civilized existence" (1990, p.14).

While this is obvious for systemists, who possess **methods** and **models** for consensual **modelization** of large scale situations, and techniques for **design** to be eventually applied, unfortunately such techniques are still ignored by most of the generally self-appointed managers.

3062

SIZE (Critical)^{1) - 4)}

The limit of a system's size, either inferior, or superior, which impedes its **survival**.

Any system, individual or social, has size **limits**: a minimum one below which it cannot organize itself and a maximum one beyond which it is not anymore able to sustain itself.

These size **limits** are defined by various interconnected conditions, namely:

SIZE (Minimum accretion)

Systems need a minimum number of coordinated **elements** in order to acquire sufficient **variety** by their possible **interactions**.

M. BUNGE calls this the "**threshold size**" "below which the **aggregate** does not form a system" (1979, p. 37).

Only when a critical mass is obtained does the system-forming **process** become able to dominate centrifugal forces or to polarize the uncoordinated **behavior** of free **elements**. For example, according to D. GORDON: "The size of the (ant) **colony** determines the number of **interactions** between individual ants, which results in a **change** in the **dynamics** of the **colony**" (1995, p.55).

A satisfactory surface-volume relationship: This necessity has been explained in a quite exhaustive manner by d'ARCY WENTWORTH THOMPSON in his great classic "On Growth and Form" (1916-1952, p.22-27) (*in the chapter "On Magnitude"*).

From a systemic **viewpoint**, each **form of organization** implies a specific **interrelation** between **invironment** and **environment**. As the **environment** grows, the **inputs** of the system must grow proportionally and this increasingly taxes the **environment**, as well as the more or less permeable **boundary**. As for similar shapes the surface increases as the square when the volume does it as the cube, there is a definite **limit** beyond which the **interfaces** between the system and its **environment** is not anymore able to provide the system with sufficient **inputs**.

Density: A minimum density is needed for the system to be coherent, lest **communication** becomes too difficult and costly, or even downright impossible. However, when density turns excessive, **communication** becomes blocked by the sheer **crowding effects** in **space** and **time**.

M. RIDLEY emits the hypothese that, for human beings, there is a "natural group size" of about 150 individuals.

This is roughly "... the number of people in a typical hunter-gatherers band, ... in a typical religious commune, ... in the average address book, ... in an army company.....

It is, in short, the number of people we each know well" (1996, p.69).

Once over this natural size, the **organization** of the group could show a lessened **fitness**. This could lead to the necessity to integrate various **groups** into a wider supergroup, i.e. lead to **emergent hierarchy**.

It would be interesting to research this **model** as a general systemic condition in other types of **groups**, as for instance, **networks of neurons** in the **brain**, or **networks** of participants in an Internet site.

Communication rate: The **coherence** of a system depends on a **communication** between **elements** and **subsystems** at a **rhythm** sufficient to maintain their **interactions**.

The **communication time** is directly proportional to the media's velocity and inversely proportional to distances. The first factor, may compensate the second one: Modern telecommunications are quickly "shrinking" the world.

Regulation and control cost: As a system grows and differentiates, the **interrelations** between its **elements** and **subsystems** must be growingly monitored and regulated in order to avoid internequine **conflict**. Moreover, **complex systems** tend to need and built **hierarchies** and pyramidal **controls**, which absorb a growing part of the available **resources**.

When the cost of **regulation** and **control** becomes overtaxing, the system finds itself exposed to self-destruction by **sclerosis**.

Moreover, an old or aging system loses much of its **adaptability** which causes **communication** and **control** problems. As a result, while its size remains unchanged, it may become unmanageable.

M. BUNGE relates the maximum possible size with a number of **components** "above which the system breaks down" (1979, p.37).

Ian I. MITROFF and Harold A. LINSTONE explain: "... all **processes** have an upper **limit** to their **efficiency**. At some point bigness boomerangs on itself. Instead of leading to greater end benefits, it produces negative end **effects**. These negative benefits are almost impossible to foresee and go completely counter to the hypothesized benefits of bigness" (1993, p.13).

Limits to size is thus a general functional and structural **rule**.

3063

SIZE (Optimum)^{1) - 2) - 4)}

The functional efficiency of a system is related to its size, which in turn depends in some measure from the nature of its **environment**. Marine mammals, for example may be bigger than terrestrial ones, as they benefit from water buoyancy.

In a similar way, the optimal size of a **group** or society (insect or human) is a **function** of its **communication means**. This may explain why some past empires declined and fell: overextended **communication lines** (as related to **communication means**) and consequent **time lags** in needed reactions may have been a cause of disruption.

It also explains why archaic **groups**, as for example equatorial forests dwellers, living off quite limited natural **resources** exploited with very simple tools, cannot reach a high **population level**.

3064

SLAVING PRINCIPLE^{1) - 2) - 4)}

The **control** of many **variables** in a system by an **order parameter**.

This principle, basic in **synergetics**, has been introduced by H. HAKEN (1983). It involves an important mathematical formalism which cannot satisfactorily be reproduced here.

This "enslavement" (such a disagreeable language!) results of the final synthesis of multiple **constraints** between **elements** in confinement when the number of **elements** increases and/or the available **space** is progressively reduced.

The slaving principle reflects somehow the transit from statistical **randomness** toward global ordering. (H. HAKEN & A. WUNDERLIN, 1990).

→ System (Composite)

Accordingly, HAKEN states that the **order parameter** is shaped by the **interactions** between individual **elements**. Once it "coagulates" in the form of a higher **level regulator**, it takes the **control** of the system as a **whole**. This is a very general **phenomenon**: for instance in laser light, in clouds rolls, in social amoebas, in fashion fads and in political **ideologies**.

For some interesting structuring examples, see "**Belousov-Zhabotinskii reaction**"; "**Bénard's instability**"; "**Dictyostelium discoideum**"; "**Hexagonal space filling**"; "**Soliton**"; "**Stigmergy**"; "**Swarm**".

The slaving principle could be very significant for sociology.

3065

SLOVENIAN SOCIETY OF SYSTEMS STUDIES¹⁾

This Society includes mainly scholars interested in so-called "General Systems" from Slovenia, but also Austria, Croatia and Germany.

Its center is at the University of Maribor and it has been impulsed since many years by Matjaz MULEJ, his colleagues and collaborators.

It has also close connections with scholars in India and the USA.

The most recent work of the group: "System Thinking and Climate Change System (against a big "Tragedy of Commons" of all of us", 2002) is an outstanding demonstration of the practical value of **systems thinking** as applied to vast and complex issues.

→ **Mitwelt; "Nothing but " fallacy; Responsibility in Systemic terms**

3066

SLOW-DOWN^{1) - 2)}

The characteristic lengthening of **adaptation time** in physical systems near **saturation** or in **ageing living systems** or **organizations**.

Slow-down seems to be provoked by the existence of a **limit** to the number of possible adaptive combinations of **elements** or **characters**.

It is reflected for example in **growth curves** of **logistic** type, representing the progressively reduced **rate** of expansion of some technological innovation, or of the renewed diversification of a severely disturbed **ecosystem**. It corresponds to a **negative feedback**, generally related to some **environmental** factor, which produces a braking effect.

3067

SMALL WORLD²⁾

"A network containing many **nodes** that have a few **links**, together with a few nodes- or **hubs**-with many links"(A. FROOD, p. 33)

FROOD connects this **model** with the **power law distribution**: "This arrangement...greatly reduces the number of steps needed to link any two **nodes**, compared with a completely regular **network**"(Ibid)

According to A. LASZLO BARABASI (Univ. of Notre Dame, Indiana) "The very **topology** of these **networks** plays a crucial role in how these systems behave". And "finding that food **webs** follow a **power law distribution**, just like we see for the **cell**, and the internet, suggests that nature displays a high degree of economy when it spans its various **networks**-it uses the same blueprint for most of them"(Ibid)

3068

SMALL WORLD EFFECT²⁾⁴⁾

A property of a **network interconnection** grid in which some apparently unrelated and widely separated **elements** turn out to be directly connected.

This is a general characteristic of many **networks**, whose importance has been emphasized by D. WATTS in a recent book (1999).

It appears when a few (even very few) **elements** have long-range **connections**, which put in contact some widely separated ones.

This is an intermediary **state** between **networks** wherein **elements** are only connected to their close neighbours and those wherein some **elements** are globally connected in a **random** way. Some few long-range **connections** in a **network** allow for the swift and efficient long-distance **propagation** of initially local **effects**. A limited number of this type of **connections** introduces specific **constraints** in the **network**. This should not be the case if too many long-range **connections** would be introduced in a completely **random** way. (R. MATTHEWS, 1998, p.7)

The presence of **constraints** in "small worlds" **networks** introduces a kind of **fuzzy** global **communication** ordering, even if the network lacks an organizational center.(R. MATTHEWS, 1999, p.27). This could be for example the case of the general **brain organization**, or the world's scientific research **community**. In both cases, a reduced number of specific long-distance **links** is enough to create a global **coherence** when each of the linked **elements** has its own regional or specific **network** of connections whereby or wherefrom it can relay any **information**.

Small world models could be very useful for the study of the present **globalization** trends in ecology, economy, **communication networks**, business, politics, social organization, cultural evolution, etc.

The small world **model** can be useful in widely different **situations**, as for ex. in epidemiology, in **brain** studies, in electronic circuits, in **communication** and **energy** distribution networks (... and their failures!), in fads and fashion **propagation phenomena**, etc...

→ **Hypercube architecture**

3069

SMOOTHING²⁾

A technique to eliminate supposedly **random** variations in **data flows**.

K.De GREENE states: "The smoothing or averaging of **information flows** in **system dynamics** can be thought as an attempt to achieve perfect **information**. There is no 1:1 **relationship** between a smoothed **information variable** and the true physical **variable** it rep-

resents. As in the real world and in all realistic **models**, **information** in **systems dynamics** is subject to bias, amplification, attenuation, **noise**, and **delay**" (1994, p.3-21).

Quoting FORRESTER (1961, p.407), he adds: "Smoothing is a **process** of taking a series of **past information** and attempting to form an estimate of the **present** of the underlying significant content of the **data**". De GREENE comments: "Smoothing is done to attenuate rapid **fluctuations** and thereby to reduce **meaningless noise**... Smoothing eliminates **random events**... it appears that a great deal of **real information** is lost by averaging and smoothing. The very capability of the system to evolve may be lost" (p.15) (for more on this, see "**Systems dynamics**").

Of course, these effects result of at least two features in **modelization**:

- 1) What is deemed *meaningless* by the modelizer;
- 2) Classical **models** of **complexity** do not take **deterministic chaos** in account and may even eliminate **data** which could reveal it.

3070

SNOWBALL EFFECT¹⁾

A colloquial way to express **percolation** effects at **critical instability thresholds**.

Snowball effects correspond to **avalanches**, panics, epidemic propagation and generally **runaway processes**.

3071

SOCIAL CYBERNETICS²⁾⁴⁾

Under these terms the Brazilian sociologist V.De GREGORY, University of Sao Paulo, proposed a cybernetic view of **human social systems**.

According to him, any society includes three typical **groups** in **interaction**:

- the "official group", a small minority that controls the social levels and generally manages society as a **whole**
- the "opposition group", also a small minority that promotes a deeply different view of what social **organization** should be
- the "silent majority" that gathers most of the people, observes a more or less passive attitude and obeys the **rules** defined by the "official group", at least as long as the general **situation** remains acceptable for them

In case of serious or deep trouble, the "silent majority" may switch their adhesion from the "official group" to the "opposition group". Socio-political disorder thus activates a **feedback** that changes the **equilibrium** of the society.

In fact, this theory would possibly be based on the **catastrophe model** of R. THOM.

→ **Backside balance; Criticality; Social pathologies; Stress; Trigger effect**

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

3072

SOCIAL ENTROPY⁴⁾

"A **measure** of the natural **decay** of the **structure** or of the disappearance of **distinctions** within the **social system**" (K. KRIPPENDORFF, 1986, p.70).

This **concept** is used by various authors. It must be however observed that it is mainly **metaphoric**. While **phenomena** of **decay** and **destruction** are evident and frequent in **social systems**, they have really never been "measured". The **concept** should be refined and given a more precise content.

It is, notwithstanding, true that **social systems** ultimately subsist on **energy inputs** and produce **entropy**, as can be seen by their production of **waste** and the frequent degradation of their **environment**.

In more recent years, K.D. BAILEY (1990, and subsequent papers) expanded the scope of the social entropy concept, stating that "we clearly need a macrosociological **systems theory** that is broad enough to incorporate nonliving **elements** such as **technology**, along with living **elements** such as social **organization**" (1998, p. 6).

BAILEY proposes his social entropy theory (SET), including "six important and interrelated factors that are used by every society- large or small- in its everyday **development**", namely **Population, Information, Space, Technology, Organization** and **Level of living** (for which he stamped a vigorous acronym: PISTOL). Moreover, or one should say, to begin with, "each society utilizes **energy**...to adapt to its particular spatial **environment**".

"This involves doing work through both its available technology, and its particular level of organization". (Ibid)

As to **entropy**, according to Bailey, if the society is successful it can be controlled at acceptable levels, this allowing the society to maintain or even increase its level of living" (Ibid)

This corresponds obviously to PRIGOGINE's **theorem of minimum entropy production** and **dissipative structuration** in **systems far from equilibrium**.

In Bailey's model if the society is "unsuccessful for any reason (e.g. overpopulation, inadequate energy resources, faulty information processing, antiquated technology or bureaucratic **pathology**) then entropy may increase, perhaps to the point where the very future of the entire society is in doubt" (Ibid)

This apparently corresponds to a violation of the minimum entropy production theorem: the society squanders uselessly a considerable part of its energy's **inputs**.

On the other hand, Bailey's views are quite critical of T. PARSONS' ones, as this author

based his social **models** on the concept of **equilibrium**, in a form that "precluded or blocked the effective analysis of social **change** in systems not characterized by equilibrium" (1996, p. 8)

3073

SOCIAL ORDER THEORIES¹⁾²⁾

Most social order theories of the 20th century are highly critical of all kind of social orders, past or present. However, viewed from a systemic angle, they seem generally weak in their deeper **understanding** of social order in general and of its basic nature.

The **Frankfurt School** theories, for example, including HABERMAS one, has marxists roots. Of course, MARX social order theory was a very original approach, as well as a socially very "engaged" one. Marx **description** was in some sense implicitly systemic, offering an **explanation** of the **structures** and **functions** that made the 19th Century capitalist society coherent and self-reproductive. But this was lost in the massive **noise** of subsequent ideological controversies and totalitarian power abuse.

In fact, social **coordination, coherence** and **dynamic stability** can be obtained only through specific devices securing organized and non-contradictory **relationships** among **elements, subsystems** and the global **entity** they constitute. A good general description of social **organization** at any **level of complexity** was given by J.G. MILLER in his **taxonomy of living systems**.

In particular, many distinct **regulations** are necessary to harmonize elements into subsystems (i.e. individuals into **groups**) and subsystems into the globally organized social entity.

Moreover, as regulations tend to order themselves into a pyramidal scaffolding at distinct levels, they are easily accaparated by the **regulators** themselves (just mere individuals exerting a specific function). In this way, regulations become **controls** and the **controllers** frequently turn self-perpetuating and reproducing, as well as oppressive.

Oppression is in fact the confiscation by controllers of means in excess of those needed to maintain **coherence** and **dynamic stability**. This devious **process** is nothing new in history as they existed in practically all past human organizations, specially political ones (Roman, Chinese, Inca, Aztec and in the Moslem World, as described by ibn KHALDOUN). In modern democracies, power becomes frequently appropriated by self-appointed "elites" or by a corrupt political establishment.

The final problem- in systemic terms- is resumed by the famous saying: "Who will control the controllers?". It derives in trying to find out some better way to obtain and maintain social coherence. A possible solution (in theory) would be universal personal **understanding** of the fundamental conditions of social order, its ac-

ceptance and the practice of universal personal **responsability**. But can this antidote to oppression and **anarchy** become a practical proposal?

3074

SOCIAL PATHOLOGIES⁴⁾

Numerous social pathologies can be usefully explored through systemic inquiry. Some examples are:

- the build-up of abusive inequalities and their stabilization through legal and political structuration;
- pathology of transculturation;
- the mechanisms and consequences of bureaucratization;
- the problems resulting from excessive **size**;
- the return to archaic political and cultural forms after the destruction of centralized or imperial **structures**.

3075

SOCIAL REFLEXIVITY⁴⁾

J. CUNNINGHAM (2001, p. 65), quotes A. GIDDENS (1990) and writes: "Anthony GIDDENS has argued that the society in which we live is increasingly the result of our own **actions**, both individually and collectively, a condition he refers to as social reflexivity. He counters the common assumption that as we acquire more and more **knowledge** of the world and build **structures** of society, we will gain **control** over our lives. Quite the contrary, we "manufacture" **uncertainties** that give us more **choices**, diverse possibilities, less clarity about an appropriate **action**. Modern technologies such as the World Wide Web have contributed greatly to social reflexivity and I argue that traditional **models of education**, emphasizing as they do inductive and deductive **processes**, are inadequate to the modern technological **context**.

"...I propose that **abductive** reasoning is a more powerful mode for navigating the **uncertainties** of the Information Age and promoting a **semiotic reflexivity**" (Ibid)

In short, **conversation** should become our best way to discover ways to permanent **adaptiveness**. Of course conversation must be conducted through efficient reciprocal understanding if we are to avoid the universal Babel Tower effect. This implies the necessity of an appropriate- and also reflexive- **language**

3076

SOCIAL REPRESENTATION

→ **Representation (complex)**

3077

SOCIAL SCIENCES METHODOLOGY: A CRITIQUE^{2/4)}

M. MARUYAMA criticizes in the following terms some methods used in contemporary social sciences:

"During the 2nd half of the 20th Century, social sciences and psychology have taken a course which, while attaining considerable results, built a skewed orientation in their theories and methodologies:

"1. The classificational **logic** which became dominant separated rather than related various aspects of our ways to organize **knowledge**, aesthetic preferences, **concepts** of what is respectable and moral, composition, **choice** of scientific theories, etc...

"2. **Disciplinary** and subdisciplinary inbreeding not only confined the researchers in fragmented **niches** of knowledge, but also amplified the peculiarity of the theories and methodologies of each niche;

"3. The **ideology** of controlled **variables** nurtured the **habit** of ignoring the wider **context**;

"4. Formalized and standardized methods of **analysis**, made easier by **computer programs**, fostered blind faith in and reliance on the "magic box" computer to the extent that many of the researchers lost their habit to use their **brain** to think, analyse or interpret the data directly or raise questions regarding the nature and applicability of specific **computer programs** they use;

"5. **Data** collection became formalized and standardized, and many of the researchers lost direct touch with raw **experience**, to the extent of not trusting one's own **observation** and accepting only the **measurements** filtered through instruments;

"6. General theorists who rose as a **reaction** against specialization tended to have an aversion to specifics, and to look for superficial **analogies** and far-fetched **similarities** with a priori **assumption** of universality and propensity to wishful homogeneization;

"7. Some general theorists used ad hoc mathematical **models** which were either too simplistic or artificially complicated;

"8. Remedial attempts of **interdisciplinary programs** ended up either with a haphazard collage or a bazaar shopping for hunting and gathering of those ideas, filtered to take home which fitted what was inbred in the home niche. The interbreeding failed".

MARUYAMA, who has a wide experience of living in a number of different **cultures**, (just as this editor) proposes some remedies:

"A solution is **outbreeding**. One has to go out from the ingroup niche, get the feet wet and hands dirty with raw and contextual **experience**. Observational ability for details and **contexts** must be regained. Relations which escape standardized data collection and instrument **measurements** must be recaptured by

using one's senses and **brain**. One must also step in several other **niches**, learn their theories and methodologies, and create new ones on *their ground*".

In his paper, the Japanese author gives "examples of the current state of what he calls

"the art of relationality, outbreeding and contextual experiencing"(1998, p. 91-108)

3078

SOCIAL SOFTWARE

→ **Ethics (Normative)**

3079

SOCIAL SUBSYSTEMS^{2/4)}

As stated by O. THYSSEN (1995, p. 17): "Modern societies (as distinguished from traditional) are divided into functional subsystems such as economics, science, politics and intimacy".

These distinctions are LUHMANN's, who also added religion and law.

THYSSEN adds: "Each subsystem is closed and creates its own **domain** allowing only certain **operations**. As a consequence, it is not possible to observe- or handle- society as a **whole**, as no vantage point exists from which to do so. As a further consequence it is not possible to talk about what is rational for society as a **whole**, or what will benefit society as a whole".

And "A functional subsystem has limited possibilities of observing and cannot observe "the world as it is". Economics cannot observe "real needs" and politics cannot observe "real voters". What they can observe are **diagrams** showing changes in sales or in voter support" (Ibid)

This kind of global social agnosticism should possibly be relativized. There are clearly positive or negative **symptoms** of the state of a society as a whole. It sometimes loses **coherence** as a whole, particularly when the distinct subsystems enter in **conflict** and do not anymore negotiate stabilizing balances between their possibly conflictive needs, **aims** or **beliefs**. This is a result of disfunction of the social **regulators** and **controls** and, or inoperancy of A. SMITH "invisible hand"

This incipient trouble can readily be observed, through a spreading uneasiness and increasing civil protest or rebellion.

3080

SOCIAL SYSTEM⁴⁾

1. "An adaptive and **complex system** composed of causally related **components**" (B. BANATHY, 1973, p. 88).

2. "A **concrete system** composed of animals that a) share an **environment** and b) act upon other members of the system, either directly or indirectly, in ways that are cooperative in at least one respect" (M. BUNGE, 1993, p.212).

Sociosystem seems to be a perfect synonym for social system. M. BUNGE states: "Every society is a sociosystem but the converse is not true: industrial plants, schools, and clubs are sociosystems but not societies. A society is a self-reliant sociosystem".

Accordingly: "A sociosystem is a society if and only if it is self-sufficient, i.e. does not depend entirely upon other sociosystems" (1979, p.177).

According to BUNGE: "The systemic view of society should not be mistaken for the *organismic* view, a variant of **holism** according to which sociosystems are **organisms**. Surely, the **components** of sociosystems are alive; besides, sociosystems are born, develop, and become extinct. However, they are not alive: if they were, then all of the peculiar laws of the living, and in the first place those of genetics, would hold for them. But these do not, hence sociosystems are not alive. Nor are they dead: the categories of life and death do not apply to sociosystems" (1979, p.241).

The organismic view is merely a not very satisfactory **metaphor**.

However B. BANATHY and M. BUNGE's definitions show that the **concept** of social system may considerably exceed the **limits** of human systems. In some sense, any **complex system** is a social system and one of the most important tasks still awaiting **systemics** is the construction of an integrated theory of **sociality** or **associativity**, as it could be called.

Such social systems are any kind of integrated **networks** of **components**, with specific **constraints** commanding their functionality.

The concept of social system was born independently from **General Systems**. As a result, some misunderstandings pervade its sociological use. They appear neatly in J.W. LAPIERRE who (according to M.N. SARGET) "... differentiates five social systems: the bio-social system, the ecological system, the economic system, the cultural system and the political system" (SARGET, 1993, p.373; LAPIERRE, 1974).

Any social system is necessarily "bio-", i.e. made of **living systems** (unless we consider atoms or molecules as social systems...). Such bio-social systems are inevitably inserted within an **ecosystem**, of which they are a **subsystem**. As to the economic, the cultural and the political systems, they are really **subsystems** of any (**human**) **social system**, forming a complex interacting network (of networks). LAPIERRE's ideas are basically sound and even systemic, but his vocabulary could induce serious confusions.

LUHMANN views social systems as systems of **communication**, which creates their own unity, **structures** and **elements**.

This very general concept obviously applies to:

- social phases in **congeries** of normally non-connected individuals. An example is **Dicystelium discoideum** and another, less constraining is a locusts **swarm**
 - social insects among which communication has a biochemical origin (**pheromones**) and is absolutely basic for the communal **activity** (**stigmergy**)
 - human groups and societies, wherein **languages** of various types are the basis for communication
 - social **automata**, for which **parallel distributed processing** seems to herald future complex societies of **automata**
- **Autopoiesis: about Luhmann's view**

3081

SOCIAL SYSTEM (Growth of a)⁴⁾

The growth of social systems tend to be **logistic** and to flatten out after reaching some **level** that corresponds to the general type of the system.

D.M. GORDON for instance observed that an harvester-ant **colony** stops growing in **size** after about five years. She moreover showed that: "The **size** of the colony determines the number of **interactions** between individual ants, which results in a **change** in the **dynamics** of the **colony**", until its **organization** stabilizes "about the same time it stops growing in **size**" (1995, p.55).

It thus seems that optimum internal **organization** corresponds to some optimum **size**. This could also be interpreted in terms of optimal **communication**: neither insufficient because of a low number of participants, nor **overloaded** by their excessive **density**.

3082

SOCIAL SYSTEM (Human)⁴⁾

"A social system composed of human beings and their **artifacts**" (M. BUNGE, 1993, p.212).

M. BUNGE distinguishes among human social systems:

"1. **Natural or spontaneous** if and only if it is self-organized (i.e. if it emerges spontaneously by **reproduction**, accretion or self-assembly)". BUNGE's examples are: "Families, street-corner gangs, and bands of hominids".

"2. **Artificial or formal**, or an **organization** if and only if it is other-organized, i.e. set up and maintained according to explicit plans and **rules**". BUNGE's examples: "Schools, churches, business firms, and government departments are artificial systems" (Ibid).

E. JANTSCH and C. WADDINGTON considered however that: "The evolutionary **paradigm** is still almost totally neglected by a social science which finds its purpose in reducing the human world to the **equilibrium** perfection, structural unambiguity and permanence, **hierarchical control**, and **predictability** of **machine-like structures**" (1976, p.2).

G. VICKERS also insists on the dynamical nature of the human social system and describe it as: "... a **set** of ongoing **relations** between persons and **organizations**, governed by mutual expectations which are usually embodied in **roles**. It is of course a very complex **pattern**. Each of us forms part of several **subsystems** and each of these is incorporated in varying degrees in others...

"... we distinguish something that we regard as a continuing **entity** but only to the extent and in the **field** in which it maintains, through **time** two **sets** of **relationships** which are themselves intimately linked – the internal ones which relates its members to each other and the external one which links it, as a **whole**, to its surround. The entity is in fact a **pattern** of **relationships**, subject to **change**, but recognisably extend in **time**" (1967, p.59).

Such a description seems to fit however *any* social system, be it a trade-union, a beehive or even possibly, up to a point an **ecosystem** or a **brain**.

In a closely related sense, T.R. YOUNG and G. SWARTZMAN observe that "... all social systems depend upon **information flow** in order to survive as **thermodynamical entities**" (1974, p.259).

Organizationally closed **values subsystems** are the most important **sources** of such **information flows** in **socio-cultural** or **socio-historic systems**. **Information flows** also seem to exist in insect societies, albeit in different forms.

In the restricted sense of human systems, R.L. ACKOFF and F.E. EMERY propose the following definition: "A system whose **elements** are **purposeful** individuals" (1972, p.215).

3083

SOCIAL SYSTEM THEORY AND DESIGN¹⁾²⁾⁴⁾

Early in the development of **systems thinking**, very important proposals were enounced by C. West CHURCHMAN (1968, 1971, 1979) mainly related to the design of social systems. Churchman, a pioneer in **operational research**, became early disillusioned by its limited scope. He quickly veered toward a much wider **approach**. He recognized that many different worldviews are possible. As a result he tried to "develop a **holistic, interdisciplinary**, experimental science addressed to problems in social systems" (M. JACKSON, p. 222, 2000) Consequently "...it becomes clear that **subjectivity** should be embraced by the systems approach. Systems designers must accept that completely different **evaluations** of social systems, their **purposes**, and their **performance** can and do exist. The only way we can get near to a view of the whole system is to look at it from as many perspectives as possible" (Ibid, p. 222)

Churchman himself states (inspired by the pragmatist philosopher E.A. SINGER): "...the Singerian inquirer pushes **teleology** to the ultimate, by a theory of increasing or developing purpose in human society: man becomes more and more deeply involved in seeking **goals**" (p. 254, 1971)

He remains however cautious. In JACKSON's words: "For Churchman, systems and whether they work or not are in the mind of the **observer** rather than in the real world. A **model** can only capture one possible **perception** of the nature of a system. **Objectivity**, therefore, can only rest upon open debate among holders of many different perspectives.

And the results of a systems study can only receive their guarantee from the maximum participation of different **stakeholders**, holding various worldviews, in the **design process**" (p. 224, 2000)

These views have been echoed in distinct ways by various systemists. Bela BANATHY Sr. used it as a springboard toward a **methodology** of design oriented to idealistic projected **goals** (Fuschl and Asilomar Conversations).

However, even a **consensus** among various **observers** obtained through conversations does not guarantee that all important aspects have been considered and integrated. **Under-conceptualization**, as described by J. WARFIELD (or FOURASTIÉ's ignorance of ignorance) remains always possible.

In such cases, idealistic design can be led widely astray and produce less than happy results. No good design can be obtained merely through generous intentions.

This is why R.A. BRYER, for example, taxed Churchman's work as "idealistic and impractical". Of course "realist and practical" ways are frequently used as cover-ups for opportunistic and even dishonest design.

JACKSON expressed this as follows: "(Churchman) assumes that genuine participation in dialectical debate can be arranged and that there is a possibility of achieving synthesis. To those who see the social world as characterized by **asymmetry** of power, structural **conflict**, and contradiction, these are pious hopes indeed" (Ibid, p. 226)

Anyhow, Churchman's views represent a lively current in the systemist movement and his methodological proposals have exerted a far-reaching influence on many systemic thinkers. A good example is the development of the **concept** of **Evolutive learning community**, elaborated mainly by Alexander LASZLO during the 1998 Fuschl Conversations.

→ **Design conversations; Design (Co-participative); Design culture; Design (Generic); Design inquiry; Design (Systems); Generic design science; Group Technique (Nominal)**

3084

SOCIAL SYSTEMS DESIGN METHODOLOGY^{1) - 2) - 4)}

An open discussion procedure for the **design** of adaptive **social systems** in **communities**.

This methodology derives from **co-participative design**, as introduced by the **Fuschl Group**.

SSDM has been proposed by G. DYER, who describes four stages in such **processes** (1995, p.8):

1. "Introduction: This stage envisages an Initiator who believes that a **social system** redesign is necessary and who then approaches another member of the **community** with a Draft **Declaration of Interdependence** as a way forward".

The Initiator should clarify the terms **independence**, **dependence** and **interdependence** as a conceptual foundation for SSDM.

2. "Development: This stage assumes that with two people now committed to the **design process** further cascading takes place. Further amendments to the Declaration take place and at some stages, meetings are called to clarify points that have been raised".

"The Declaration must be presented as a continuously evolving ideal – members of the **group** must be reassured that they have the right to suggest amendments to both the **domains** and details within **domains**, or indeed to suggest entirely new **domains**".

3. "Incorporation: This stage includes the possibility of a Draft Bill of **Rights and Responsibilities**, being developed by dialogue to incorporate the **community's** agreements"

This includes "freedom of expression" and "freedom to act". "Responsibility" includes "recognise that **actions** will be seen to be inappropriate if they place others in a position of vulnerability".

4. "Review: "... individuals will be reflecting on their experience of being a member of the **design** team in the absence of any prior formal education in **systems design**, their experience becomes their education" (Ibid).

This type of design through group dynamics should be compared with WARFIELD's **Nominal Group Technique**. It seems to lack a technique to avoid **underconceptualization**, but it has strong positive psychological effects.

3085

SOCIAL SYSTEMS MODELING^{2) - 4)}

According to P.M. ALLEN, "we find three basic issues that must be addressed in modeling social systems:

"A social system is firmly embedded in an **environment** with which it exchanges **matter** and **energy**, and it also has an internal **complexity**. Both these realities can, at certain moments, modify the average **behavior** of the system.

"The **evolution** of such a system is an interplay between the average **behavior** and rationality of its actors, and the **fluctuations**, **deviations** and **perturbations** around this average caused by the **environment** and by individuals within the system. Such an **evolution** involves both **determinism** and **chance**. The former is associated with the **variables** contained in the reduced **description**, and the latter with **perturbations** that probe the **stability** of the system continually, but which are not contained in the reduced **description**.

"The **evolution** is described by a branching **tree** of possibilities in a **space** of increasing **dimensions** representing the qualities which are associated with the system. The branches are merely self-consistent or stable expressions of the **organization** and **interactions** of the **elements**. The **structure** becomes unstable and changes when it cannot cope with either internal or external **fluctuations**. (1982, p.35-37).

3086

SOCIAL SYSTEMS PARADIGM⁴⁾

K.C. BAUSCH describes a social systems paradigm which, in his opinion, emerges from convergent agreement among systemic thinkers (1998, p. 11)

He writes: "This paradigm unites insights about **dissipation** and **autopoiesis**:

"1. Social realities are **dissipative structures**

a. they are totally temporized

b. they are ongoing **patterns** that are maintained by their manner of continual **reproduction**

c. in **far-from-equilibrium** conditions, these realities are open to **bifurcations**

d. in far-from-equilibrium conditions, small influences can generate profound **evolutionary effects**.

e. an optimal **strategy** to create profound **change** is to concentrate energy at likely **bifurcation** points

2. **Social structures** are autopoietic

f. as ongoing patterns of **meaning** that are constantly being reproduced, **Social** systems structure their reality on the basis of expectations in order to cope with the complexities of their existence

g. the formula for sustainable and creative existence is to multiply contradictory expectations and to hold them as alternatives for futures **uncertainties**" (Ibid)

As observed by Bausch, these characteristics are closely related to technology, whatever the level attained by less or more evolved social systems.

→ **Autopoiesis; Energy; Entropy (Social); Santiago theory; Systems (Co-operative)**

3087

SOCIAL TIME

→ **Time binding; Time domain; Time frame**

3088

SOCIALITY^{1) - 4)}

The condition of a large **group** of **elements** which interact permanently in a coherent way.

Sociality seems to be somehow implicit in nature. Inherently, **elements** tend to interact, producing some order See "Order parameter"; "Power laws" and "Slaving principle". F. David PEAT writes, commenting on the slime mold (*Dictyostelium discoideum*): "The slime mold... shows how collectivity and individuality, **holistic** and **reductionist** aspects can exist within the same system. What is particularly interesting about the slime mold is the way how collective or **holistic behavior** is enfolded within the individual, and likewise, individual **behavior** is unfolded across the **whole**. The individual and the global **elements** are both contained one within the other – an approach that clearly requires a new mathematical approach to nature" (1987, p.67).

This aspect is manifest, for instance, in H.von FOERSTER magnets experiment, demonstrating "order from noise".

The maintenance of sociality implies **stability** through **organizational closure**. This seems generally true in all kinds of **social systems**, including archaic **human systems**. The accelerating **transformations** of contemporary human societies confront us however with a riddle in this sense, as closure of specific cultures is now challenged.

Sociality is still an insufficiently researched concept. Many aspects of it remain imprecise:

- which conditions predispose **elements** to **association** and why;
- which types of **elements**, specially **heterogeneous** ones display a tendency to associate;
- how do the **interrelations** become established and how are they **regulated** or **controlled**;
- why do some **elements** associate in a lax way, while others tend to form **complex** and **integrated systems**;
- how and why can a **composite system** (i.e., with lax **associations**) become an integrated one.

The aim of such a research would not be "socializing" all sciences, but find general **isomorphic models** for this quite universal **behavior**.

Sociality is even possibly related to the physical coordinating **process** at work in the formation of **solitons**.

Up to now, the most comprehensive view of sociality as a **phenomenon** closely related to **evolution**, in very general terms, from physics to biology, has been written by Carsten BRESCH (1977).

Other significant contributors were W. SCHWEMMLER (1989 and 1991) and J.T. BONNER (1993), mainly from a biological viewpoint.

¹⁾general information

²⁾methodology or model

³⁾epistemology, ontology and semantics

⁴⁾human sciences

⁵⁾discipline oriented

3089

SOCIALITY (Two types of)¹⁾²⁾⁴⁾

Sociality can be obtained through **interactions** either among very numerous individuals in a closely knit collective **organization** (an anthill, a beehive) or a small **group** of highly brained long living individuals (whales, elephants).

In both cases, the basic character is the **transmission of information**, massively distributed in the first case, or concentrated in specific bearers in the second one.

Human societies obtain probably their exceptionally high power of **organization** to the fact that individuals are at the same time very numerous, highly brained and long living. (see: WEIGART et al., p.278-87)

3090

SOCIALIZATION^{1) - 4)}

The **process of integration** of numerous interacting individuals into an emerging organized **whole**.

Socialization appears as a very general tendency in **living systems** at every **level of complexity**, from cells to insect societies and **human systems**.

It supposes a specific ordering of the **interrelations** among **components** and a long permanence in **time** of the global **organization** thus obtained (**time binding**). This implies in turn the need for its **self-reproduction** and a permanent **process of learning**.

The socialization **process** implies deep modifications of the society's **components**, which must enter in specific and differentiated **interactions**. In this way, some individual characteristics are considerably reduced, while the **interactions** introduce specific **links** by *orienting the elements behavior*.

3091

SOCIEDAD ESPAÑOLA DE SISTEMAS GENERALES (SESGE)¹⁾

The Spanish Society for General Systems was founded in 1982 by a group of Spanish scholars under the leadership of R. RODRIGUEZ DELGADO (its late honorary President), in Madrid.

After publishing for a time a Newsletter, it created the "Revista Internacional de Sistemas" in 1989, which publishes papers in English, French and Spanish related to theoretical and applied **systemics** and **cybernetics**.

It also contributed to the organization of so-called **Fuschl Conversations** in Spain (Alicante; Valencia).

Under the impulse of members of the SESGE, an Association of Systems was also created in Valencia and, in the same city's University, a Faculty of Systems was created in 1992. It is however mainly oriented to **Operation Research** and **Systems Dynamics**.

Another member of SESGE, J. ARACIL, of Sevilla University, is the main Spanish specialist in **Systems Dynamics**.

After the death of its founder, the seat of the SESGE has been transferred to the València University, where interesting applied systems studies are continued, mainly under the leadership of Antonio CASELLES.

The president of the SESGE is now Lorenzo FERRER, at the same University.

In Madrid the sociologist Francisco PARRA-LUNA (Universidad Complutense) applies systemic **concepts** and **models** to his discipline.

3092

SOCIETAL ORDER PARAMETERS^{2) - 4)}

K.De GREENE proposes this specific use of the concept of **order parameter** to living and specially to human systems. He explains: "When applied to complex **living systems**, order parameter describes the evolutionary waxing and waning of the system. The order parameter is a macroscopic collective **field**, **emergent at critical points** out of myriad **interactions** at the **microlevel**. The order parameter expresses stochastic generation of the new (structural **change**) and **deterministic** maintainance of the now established (structural constancy). The **emergence** of the order parameter represents a great loss of **degrees of freedom** at the **microlevel**; **microlevel behavior** now becomes **slaved** to the order parameter. Human **languages**, the great theistic religions, political belief systems, economic belief systems, and scientific/societal belief systems like the Newtonian **paradigm** are example of order parameters" (1994, p.12).

De GREENE offers a very interesting table of characteristics of Societal Order Parameter in human societies comprising ways of **values** creation and transformations, social **learning**, social **bifurcations**, and **long-wave cycle structure** (p.13).

The German systemist N. LUHMANN offers a similar view of the **dominance** of the social system, whose intrinsic global logic overwhelms the individuals. As resumed by M.C. JACKSON: "Humanity is dragged in the wake of the system. Individual hopes and aspirations simply respond to the system's **needs**, and **consensus** is engineered to improve the system's functioning. Even internal dissension, strikes and **conflict** represent the system readjusting to increase its **viability** and **effectiveness**" (1992, p.33).

The progressive destruction-absorption of small archaic societies by and within great **cultures** seems to be another similar **phenomenon**, in this case also favoring global **efficiency** and internal **differentiation** to the detriment of lesser social units. Inefficient gigantism does however lurk.

Societal order parameters can also be observed in animal societies, specially but not exclusively in social insects.

3093

SOCIETY for GENERAL SYSTEMS RESEARCH¹⁾

The original scientific body dedicated to systems research.

The Society, states K. BOULDING, "originated in a conversation around the lunch table at the Center for Advanced Study in the Behavioral Sciences in Palo Alto, California, in the fall of 1954" (1972, p.79). It was officially founded in December 1954, under the leadership of the Palo Alto initiators: L.von BERTALANFFY, a biologist; K. BOULDING, an economist; R. GERARD, a physiologist, and A. RAPOPORT, a bio-physicist. It was named at that time the "Society for the Advancement of General Systems Theory". The name was changed for the first time in 1957. It published from 1956 till 1984 a Yearbook containing a selection of the best papers on systems and **cybernetics** and still organizes a yearly meeting in different places in the world. Its membership is completely international and it has National Divisions and Regional Chapters, as well as Special Interest Groups.

The four basic aims of the Society were defined as follows:

- To investigate the **isomorphy** of concepts, **laws**, and **models** in various fields, and to help in useful transfers from one field to another.
- To encourage development of adequate theoretical **models** in fields that lack them
- To minimize duplication of theoretical effort
- To promote the unity of science.

According to a survey organized by G. KLIR in 1978, W. ROSS ASHBY (1903 - 1972) was by far the most influential person in systems movement. KLIR states "The great impact of ASHBY's work on systems movement can be explained, at least partially by the superior clarity of his writings, his unusual capability to recognize important principles where other see only trivialities, his great gift for essence preserving **simplification**, his broad interests, encompassing both cybernetics and general systems research, and his meticulous scholarship" (1991, p.36).

Since 1988 the name of the Society is "**International Society for Systems Science**". (see the corresponding entry for other details)

3094

SOCIOBIOLOGY¹⁾²⁾⁴⁾

"The systematic study of the biological basis of all social **behavior**" (E.O. WILSON, 1975, p.4)

Sociobiology is concerned with the **behavioral interactions** among members of the same species.

It has been a controversial subject since its appearance.

This seems to have resulted in part of its uses for explaining human behavior without much reference to the **complexity** of human **brain** and mind, which obviously vexed some sensibilities.

However, while men and mankind are an extreme case of a socially organized species, precisely because of the impact of higher mental faculties, the **emergence** of **socialization** in man is a result of **synergistic effects**, which are present since the lesser **levels** of life (P. CORNING, 1998b) and even possibly at the chemical and physical levels (C. BRESCH, 1977).

3095

SOCIOCULTURAL SYSTEM ⁴⁾

E. LASZLO proposed the following classification of sociocultural systems with their basic characteristics (in order of growing **complexity**):

- **Kinship system:** Kinship **organization** (Family, clan, tribe); multi-purpose stone tools; human **energy**; nomadic hunting territories; hunting economy; pictograms
- **Village system:** Special purpose tools; animal **energy**; farming economy; ideograms.
- **Empire system:** Theocracy-autocracy; metal tools; inorganic **energy**; integrated economy; writing; special purpose towns; administration.
- **Nation-state system:** Democracy; machine technology; transformation of **energy**; mechanical transmission of **information**; Newtonian science. (Federal or unitary state)
- **Planetary system:** Three dimensional **boundaries**; ecumenism; internationalism; **automation**; nuclear **energy**; electronic transmission of **information**; Einsteinian science (1974, p.40).

The socio-cultural system is basically generated as a **dissipative structure**, whose **complexity** grows (in human **brains**, in economic **structures**) in proportion of permanently available **energy**.

3096

SOCIOGENESIS ^{2) - 4)}

The process of **self-organization** and **emergence** of societies.

Such a **process** takes place through growing **interactions** between **elements** hitherto independent. Through general **evolution**, sociogenesis seems to have been a **process** of recurrent **emergence** by association at successive and growing **levels of complexity** of **elements** and groups of **elements**: complex molecules, cells, **organisms**, societies of **organisms**.

According to B. CORBARA and A. DROGOU, in insect societies "...the genesis of collective **patterns** and complex collective **decisions** may result from quite simple individual mechanisms, based on reciprocally competing **positive feedbacks**" (1993, p.835).

These authors developed a **model** ("COLONY") of sociogenesis in an anthill according to which:

- Each individual is dominated by a global and permanent **behavioral algorithm** giving it at any time the possibility to opt for one of three basic individual states needed in the anthill: caring for the brood; foraging or being inactive;
- The activity of each ant is a **function** of the demand for each specific task;
- The **level** of demand for each task is a result of the global **activity** at each moment.

This should be compared with P.P. GRASSÉ's concept of **stigmergy**.

C. DELAYE and B. CORBARA describe as follows the mechanisms of sociogenesis: "The transition from **autonomous elements** to integrated ones may result from two basic mechanisms: the first, that allows separated **elements** to gather while conserving their own **closure**, is **aggregation**; the second, which introduces a **dissymmetry** among the participating **elements**, is incorporation" (1993, p.843).

This viewpoint converges with V. CSANYI's view about the **autogenesis** of systems as a result of the reciprocal effects of basic **interrelations rules**.

Until quite recently, sociogenesis has been a spontaneous and automatic **process**.

It is quite more general than the shaping of human **groups**. In some sense, even organized **groups of cells**, or neurons seem to be self-generated societies. Colonial vegetals, animal groups and even biotopes can be somehow considered as societies.

Many systemic and cybernetic **models** have some validity for the study of sociogenesis: Social **groups** are **regulated** (or even **controlled**, in the case of human societies), they are generally **hierarchical**, they offer specific **modes of growth** (**stigmergy** and **dissipative structuration** for example), their **behavior** does not allow total **predictability** and is even possibly **chaotic**, etc...

All these **models** offer new proposals to sociology.

As stated by E. JANTSCH, sociogenesis "is increasingly becoming a matter of human **design** too, and bring **culture** into play" (1976, p.54).

This is surely a reason to try to use systemic and cybernetic **models**, but altogether a reason to be very careful in order to avoid unfounded **analogies**.

Another interesting comment by JANTSCH is that, in human societies, sociogenesis becomes "... the result of overlapping functional conscious, and superconscious **modes of learning**" (ibid., p.56).

Remains to be seen if we can become conscious of... superconscious **learning**.

3097

SOCIOGNOSIS ¹⁾³⁾⁴⁾

The understanding of a society by itself.

This definition is in some sense highly unsatisfactory, because it endows a collective **abstraction**- "society"- with a capacity for self **awareness** and **knowledge**. Let us in this case use the word simply as short-hand and in brackets.

Only individual historians and sociologists are able to offer their **interpretation** of their own (or other) "society" as it was at some time in the past and as it is supposed to be presently. Their opinions are- or not- known and accepted by a majority of the members of the considered "society".

In any case, what a "society" believes of itself and of other "societies" is of absolutely fundamental importance as a prime mover of its **behavior**. In many cases, it can even make it stupid or criminal. Such aspects were described and criticized more than one century ago by G.LE BON (1895) and S. SIGHELE (1892)

A reasonably credible sociognosis should be constructed (always in a provisional way) by a wide consensus among historians and sociologists. The study of societies as complex **congeries**, or peculiar types of systems, could be a useful **methodology**.

→ **Autognosis; Social emergence; Social field; Social system; Sociogenesis; Socio-historic system; Sociolysis; Socio-technical system**

3098

SOCIO-HISTORIC SYSTEM ⁴⁾

Any organized (i.e. structured and functional) human **group** whose duration supersedes the individual life of its members.

The socio-historic system is largely **autopoietic**: it remains constantly able to replenish its membership and to maintain its internal **organization**.

This **model** applies to tribes, countries, nations, enterprises, political parties, clubs, civic **organizations**, etc... J.G. MILLER's **descriptions** of **groups**, **organizations** and societies are very helpful to understand **structures** and **functions** in the socio-historic system.

The following quotes may apply to socio-historical systems. A. RAPOPORT and W.J. HORVATH wrote: "Quasi-biological **functions** are demonstrable in **organizations**. They maintain themselves: they sometimes reproduce or metastasize: they respond to **stresses**; they

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

age and they die. **Organizations** have discernible anatomies and those at least which transform material **inputs** (like industries) have physiologies" (quoted by L.von BERTALANFFY from 1959, in 1962, p.18).

In the same quite more than analogic sense, G. VICKERS wrote: "Institutions grow, repair themselves, reproduce themselves, decay, dissolve" (1957, p.4).

Another important aspect of socio-historic systems is their evolutive succession and the progressive **emergence** of more complex ones. This could be considered the basic frame of the whole of human history.

3099

SOCIOLOGY (Systemic)²⁽³⁾⁴⁾

M. BUNGE proposes a systemic sociology whose central thesis would be that "any structured **human group**, from a family to the **world system**, should be conceived as a system, made from human beings, and possibly their **artifacts**"

Moreover, in any human society, "it is possible to distinguish four closely interrelated **sub-systems**. These are the biological system, characterized by kinship **relations**; the economic system centered in work and trade; the political system characterized by administration and power relations; and the cultural system, united by... creation and **communication of information**" (1995, p.29-30)

3100

SOCIOLYSIS^{1) - 4)}

The **disaggregation** of a **social system**.

This **process**, opposite to **sociogenesis**, implies the disappearance of **interrelations** among constitutive **elements**, each of which, if able to survive individually, becomes independent and **autonomous**.

Sociolysis however generally entails the destruction of most of the severed **elements**.

Biological death is in some sense a sociolysis **phenomenon**. This is also the case of the destruction of an archaic society or an enterprise.

3101

SOCIOSPHERE⁴⁾

"The total sphere of human activity" (K. BOULDING, 1968, p. 114).

In this article on "Business and economic systems", K. BOULDING considers from an economist's viewpoint the various **subsystems** within the global human system, each with its own particular disequilibrating **feedback processes**.

It would seem however that the sociosphere depends basically of the **resources** of the **ecosphere** and that its internal disequilibria may, in not a few cases turn into a global abuse of

the **ecosphere**, because the global **interrelation** between both is believed to be a **positive-sum game** favoring the sociosphere in a unilateral way.

Considering this, no research on the sociosphere can be complete and secure if not connected with the study of the **interrelations** between sociosphere and its **ecosphere environment**.

3102

SOCIOTECHNICAL MACROSYSTEM⁴⁾

"An evolving society (which) has social, economic, technological, psychological, political, and other dimensions, and... interacts with the natural **environment**" (Adapted from K.DE GREENE, 1991, p.69).

The notion apparently includes regions, nations and possibly the world system in the making. It will always however be difficult to define the **limits** of such a system and to describe it in a more or less satisfactory way.

→ See also Technical macrosystem

3103

SOCIOTECHNICAL SYSTEM⁴⁾

"A combination of **interacting** people and technology" (J. WARFIELD – pers. comm.).

WARFIELD adds that: "The way in which systems success is interpreted requires that the people and technology be both separately and interactively successful in order for the system to be successful".

The problem lays evidently in the **criteria** selected to define and measure "success" (Technical?, economical?, social? ecological ?, or whatever). Different people may obviously select different **criteria**, possibly incompatible in their consequences.

WARFIELD gives the following examples: "Banking systems, computer systems, **communication** systems, educational systems, environmental systems, governmental systems, private enterprises, public enterprises" (Ibid).

The following observation by N. WIENER should obviously be pondered, even if it has some luddites undertones: "...the automatic **machine**...is the precise economic equivalent of slave labor. Any labor which competes with slave labor must accept the economic conditions of slave labor. It is perfectly clear that this will produce an unemployment situation in comparison with which the present recession (i.e. 1950) and even the depression of the thirties will seem a pleasant joke" (1950, p. 162)

While fifty years later, this dire prediction still never came true, it is also true that creeping unemployment tends to become more structural and not any more merely cyclical.

This mechanism should be closely scrutinized in terms of social **self regulation** and possibly the prudent introduction of some better "checks and balances" than merely unemployment allowances.

3104

SOCIOTOMY⁵⁾

The experimental suppression of some category of specialists in a society of insects.

These experiments have been practiced in ants and in bees colonies. (C.D. MICHENER, 1974). They lead to a regression of some furtherly specialized workers to a former state, together with a physiological rejuvenation of the affected insects. This is seemingly understandable only as a result of a social **regulation** affecting the anthill or the beehive as a **whole**, and based on complex physiological reactions of the whole **community**.

3105

SOFT PROBLEM

→ Problem (Soft)

3106

SOFT SYSTEMS DYNAMICS METHODOLOGY (SSDM)²⁽³⁾⁵⁾

The combination of two well known systemic approaches for the analysis of complex **problem situations**, namely P.B. CHECKLAND's **Soft Systems Methodology** and J. FORRESTER's **Systems Dynamics**.

SSDM has been introduced by R. RODRIGUEZ ULLOA, President of the **Instituto Andino de Sistemas** (Lima, Peru), who states that "It was felt that **Systems Dynamics** did not answer very clearly (the following) vital questions:

- Under which world-view are the **causal loops** constructed which show the (specific) **phenomena** occurring in the real-world?
- Who are the **observers** and why do they observe the real-world the way they do?
- Do human affairs and natural phenomena existing in the real-world behave under a "logical" and "rational" way i.e.: Is it possible to delineate a logical **framework** of how real-world phenomena behave?, or on the contrary, is it not possible because they behave in an "irrational" and unsuspected way?

(Note: "**rationality**" can be only in the eye of the beholder. The "rationality" of the armament industry for instance is not the same as the "rationality" of sustainable **development**, or of environmental care)

- If there is an "irrationality" in the **behavior** of the real-world's phenomena, which is the "rationality" that supports it?
- Is it possible then to model that "irrationality" under a **schema** which is based on a cause-effect rationality?

- Which are the reasons under which an **observer** choses a particular way of seeing a specific **problem-situation**? Which kind of interests and **values** push them to observe the real-world in that way?
- How can someone give a "**solution**" about something, if the "problem" has not been clearly understood or if the **consciousness** of the world-view under which it is being observed is neglected (or ignored)?
- Is the "solution" provided by the **Systems Dynamics** approach culturally feasible and systemically desirable?
- What learning points can be obtained from constructing **Systems Dynamics models** and implement them in the real-world?" (R. RODRIGUEZ-ULLOA, 1999)

It is to be noted that **Systems Dynamics** proposes answers to "What if"s hypotheses, applied to a pre-established **model** of the problem-world, sometimes constructed on very shaky observational and epistemological ground, but nevertheless uncritically used (FORRESTER's warnings notwithstanding!).

Accordingly, and to complement these question marks, the author establishes an ontological, epistemological and philosophical comparison **matrix** between **Soft System Methodology**, **Systems dynamics** and the emerging Soft Systems Dynamics Methodology. This latter includes and compatibilizes all the important features of SSM and SD.

→ **Catwoe; Clanthink; Design; Groupthink; Underconceptualization**

An overview of the Soft Systems Dynamics Methodology

RODRIGUEZ ULLOA describes the stages to be followed in applying the SSDM

- **Stage 1: Description** of the problem **situation** in its un-structured form.
- **Stage 2:** Creation of a "rich picture" of the **situation** by incorporation of important aspects frequently neglected as related to "problem-owners, clients, **actors**, their worldview, level and kind of power, their **relationships**, etc." (Ibid)
- **Stage 3:** Introduction of "problem-oriented **root definitions**", which can be used "in order to describe epistemologically ..." "irrationalities". Under this perspective "**root definitions** are used to express problematic **transformation processes**, instead of expressing **transformation processes** oriented to provide "solutions" to the problematic **situation**..."
- **Stage 4:** Building **dynamic models** of the "problematic **situation**". At this stage "a problematic **context diagram** of the **situation** is built up". Of course, this **context diagram** responds to the particular **Weltanschauung** (i.e. worldview) that the **observer** has emphasized in a particular problematic

root definition. Changes in the **root definition** originate changes in problematic **context diagram** and viceversa"

- **Stage 5:** Comparison of the **systems dynamics models** against the rich picture built at stage 2. This is a **process of validation** of the **models**, tending to verify if "the **model** expresses adequately what is happening in the real - world"
- **Stage 6:** Determinate feasible and desirable **changes**. This means mainly "culturally feasible" and "systemically desirable" (i.e., excluding any self-contradictory specific or global **action** or effect).
- **Stage 7:** Building dynamic **models** of the "Solving Situation". This step is needed because no satisfactory evaluation of the **models** is to be obtained without future projections of the possible consequences of their application.
- **Stage 8:** Express the **transformation process** needed to perform "improvements" of the problematic **situation**. If "some difficulties appear at this stage, due to systemically undesirable factors, then some **adjustments** are needed between stages 2 and 7, until a "good" **adjustment** is found"
- **Stage 9:** Implant feasible and desirable **changes** in the real-world This should not be done before reaching a satisfactory validation of the **models**.
- **Stage 10:** Collect all **learning** points and save them for future study and reflection. "The **learning** points come from the **sensitivity** analysis of **modelling** the "problematic **situation**" as well as the "solving **situation**" and the proper implementation **action** in the real-world (Stage 9)

A graphical **representation** of SSDM (given by the author) is very helpful for a better understanding, in particular because the **feedbacks** among the different stages are fully graphicated.

RODRIGUEZ ULLOA's paper provides a quite complete glossary of the terms used in SSDM

→ **Catwoe; Design (Generic); Soft Systems Methodology; Systems Dynamics.**

3107

SOFT SYSTEMS METHODOLOGY ⁴⁾

A methodology to be used "in ill-structured or **messy problem contexts** where there is no clear view on what constitutes the **problem**, or what **action** should be taken to overcome the difficulties being experienced" (R.L. FLOOD and M.C. JACKSON, 1991, p.168).

This methodology was created by P. CHECKLAND (1981), inspired by C.W. CHURCHMAN's work.

J.van GIGCH had previously defined soft-systems as "Systems that may adopt several states due to environmental conditions, yet preserve their original identities in spite of these influences" (1978, p.591). He added: "Usually

these systems are found in social sciences **domain**", i.e. the **domain** where different **stakeholders** may have different views on a given **situation**, of its possible future development, and about what should be done, if anything.

I. TSIVACOU synthesizes as follows the nature of Soft Systems Methodology: "SSM is a whole composed by conceptual **models** or action plans, i.e. by graphical **representations** and **meanings** which fill these **representations**. Thus SSM is a unity of two things, inseparably connected: **models** and **meanings**. The **models**, as the formalization of a thought **process**, are cultural products with their proper **structure**. **Meanings** are expressed by social **agents** and constitute the content of the methodology" (1993, p.274).

P. LEDINGTON emphasizes: "First, SSM does not assume that the **problem** is one of rational choice... SSM assumes that the designation of the **problem situation**, the definition of the **problem**, and the possible **goals** to be achieved are all problematic **elements** in themselves (1992, p.47)..."

"SSM can be seen as an organised approach to helping develop and maintain a good **understanding** of a **situation**. Thus a basic **process for inquiry** (or **methodology**) emerges:

"First, investigate the **situation** and gain an intuitive **understanding** of it.

"Second, grasp some basic names for ideas that are felt **relevant** to the **understanding**.

"Third, formalise the ideas into **models**, using some rules of formalisation.

"Fourth, compare the **models** with the features of the **situation** and assess the areas of match and mis-match.

"Fifth, evaluate attitudes toward the **situation** in terms of **problems** and courses of **action** based upon the revised **understanding** that has emerged from the formal **process of inquiry**.

"These five steps provide an organised approach to inquiring about the **situation**. The **cycle of inquiry** may itself lead to further **inquiry-oriented action** such as the collection of more detailed **data** about the **situation**, the revision of the **model** (or **models**) used in the **inquiry**, or to the modification of **action** in light of the new **understanding**" (p.51).

LEDINGTON adds: "The basis of SSM is an exploration of the relationship between ethos and actuality. In the first stage of SSM a basic **understanding** of the **situation** and the agenda of **problems** which actors recognise is assembled. The second stage is an attempt to recognise and formalise systems **representations** thought potentially to be **relevant** to the **situation**. The concept of the human **activity system** is then employed to give **coherence** to the formalisation **process**. Thus **relevant** systems are identified and conceptual **models** are created. In the sense discussed above these conceptual **models** are grounded in the ethos

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

of the **community** rather than in the actuality of the **situation**. The conceptual **models** are then compared with the actuality. In this way SSM provides tools and techniques for exploring the relationship between ethos and actuality in an organised and open manner" (p.55).

In other words, SSM is very far to be a culturally neutral **methodology**, not by itself, but rather through the subjacent cultural **frame** of its clients and users. This **frame** should not remain shrouded in **invisibility**.

Interesting comparisons could be made with J. WARFIELD's "**Interpretive Structural Modelling**" and "**Interactive Management**".

3108

SOFT TECHNOLOGY ¹⁾²⁾⁵⁾

"The scaffolding"(support systems, **group process** techniques, **design methodologies**, **decision making** processes) for individual and collective self-determination: know-why"; "know what for"and "care why"(K. BAUSCH, Glossary, Pers. comm., 2002)

"Soft"comes in opposition to "Hard", related to **methods**, techniques and **tools** used in physical sciences and, up to a point, in biological sciences. It means that the study of all human **behaviors** is more difficult and allows for a lesser degree of certainty than experimental sciences because of the impossibility to reproduce tightly controlled sequences of **events** and the great difficulty to obtain a secure **knowledge** of historical events and experiences. As a result, the **situation** at the "starting block" is never very well known, nor objectively evaluable.

Soft technologies are still quite "in the making"and in need of a better understanding in systemic terms, specially in their psychological and cultural dimensions.

→ **Design (generic); Design (Systemic approach to); Interpretive structural modelling; Underconceptualization**

3109

SOFTWARE ^{2) - 5)}

Programs redacted in **symbolic languages** adapted for the **operation** of computers.

Computers themselves are "**hardware**", i.e. **machines**.

There is an enormous **variety** of software, adapted to many different needs, and new ones are constantly elaborated.

3110

SOLIPSISM ³⁾

The philosophical theory according to which the only "reality" is what is perceived by an **observer**.

A resurgence of bishop BERKELEY's views, solipsism is a frequent risk attached to some systemic interpretations of reality.

One may read for example that "... the Quantum version of the reality principle... asserts that only **observed events** are real" (R. FISCHER, 1992, p.216)

It should probably be better to write "real", or "realized" with quote marks, in order to convey the **understanding** that this does not negates the existence of something "out there".

The same problem may arise out of the notion of **organizational closure**, if it should be believed that the **observer** system becomes "closed" in the **meaning** that all **representations** become **endogenously** generated without any further **reference** to the "outside".

A recent comment by M. MARUYAMA rises the disquieting possibility that our mass electronic **image** culture could lead to quite generalized collective solipsistic attitudes: "This state of mind can be easily produced in an **environment** where everything is artificial, everything is like a theatre stage, every wish can be fulfilled by a push-button, and there is nothing beyond the theatre stage and beyond your **control**" (1994, p.100).

3111

SOLITON ^{1) - 2)}

A solitary **wave**, able to persist in a well-defined shape, for a long distance and an appreciable span of **time**.

According to C. REBBI, a soliton does not fades away because it is submittend to a **topological closure** (1979).

This relates this **phenomenon** to **synergetics** and shows that it must be under the **control** of an **order parameter**.

Accordingly, solitons are forms of spontaneous **self-organization**.

F. David PEAT explains: "... solitons are local phenomena that are constantly sustained through a global **activity**; they are born, persist as **patterns** in **space** and **time**, and then die back into their ground... In the case of solitons it has been possible to analyse a system into relatively independent **parts**, *within the context of the whole*... It is only when **analysis** and **reduction** become absolute and the solitons are taken for truly independent **elements** of reality that confusion sets in" (1987, p.75).

In short, solitons are forms of higher **level organization** emerging from lower **level** interactive **phenomena**.

Solitons have been discovered in many **non-linear** systems (in tidal waves, in vibrating atoms, in electrical circuits, in nerve impulses, etc.) According to F. David PEAT: "It has even been suggested that elementary particles are not in fact the fundamental building blocks of **matter** but are the solitons of an underlying **nonlinear quantum field**" (1987, p.74).

Many more uses of the soliton **model** could probably be found, even possibly in economics and in social sciences.

3112

SOLUTION ¹⁾⁴⁾⁵⁾

The elimination of a **problem** or difficulty affecting some **issue**.

However "there is no free lunch". Any so-called "solution" implies some **costs**. Moreover, as no issue can be isolated from **context** or **environment**, many solutions imply some new problem within the affected **entity**, its environment...or both. In many cases, so-called "**problem solving**" is in fact mere "problem shifting". The problem solver may be either unconscious of the shift or, in some cases, cynical about it.

In short no solution is such if it is merely a zero-sum **game** (or in cases a negative-sum one)

B. BANATHY Sr. once said: "You cannot solve a problem, you only can manage it".

He did not elaborate on his idea, but many contemporary "solutions"are clearly significant examples of bad global **understanding** and **management**

J. WARFIELD made a similar observation and objected to this use of **language** as "a form of linguistic pollution". (pers. comm.)

Moreover, what we do understand as a "solution"depends largely of some implicit **assumptions**, nearly never clearly outlined, nor even at all conscious in many cases.

1. The linear solution :corresponds to a linear view of **causality** and can be legitimately used in simple **problems** of the type: "the left front tyre is punctured. We must change it with the spare one". This remits normally to a sequence of causally simple operations

2. The interdisciplinary solution: Two interconnected simple problems can frequently be solved through consultation between two (or more) specialists. But there is a basic condition: the specialists must understand each other, i.e. each must have at least some **knowledge** of his interlocutor's trade and the way it is relevant for his own work

3. The systemic solution :To begin with, any systemic solution is merely circumstantial and most generally provisional. In this case, "solution"should be understood in a conditional way: the quality of what we understand and decide to do cannot be better than our general grasp of the **situation** within its **context**

4. Solutions in time dimension :Most of the so-called solutions are merely "for now". The ignorance of the **time dimension** and **nonlinear change** leads in most cases to new problems (whose costs are generally paid by somebody else) The time-bomb problem should be taken care of.

→ **Magic bullet; Management; Problem set; Spillover effects; Time; Trial and error; Underconceptualization**

3113

SOMATIC ECOLOGY²⁾⁴⁾⁵⁾

This term has been introduced by the biologist L. BUSS, who writes: "**Evolution** of multi-cellular forms of life is characterized by an increasing sophistication of **cells**, tissues, and **organs**, which perform somatic duties of value to the **individual as a whole**" (1987, p. 53)

In fact, this **behavior** of the **elements** (biological, social or robotic) is coupled with specific, and also more and more sophisticated **communication** means: from physico-chemical **links** to symbolic **language**, through **pheromones** and mimics.

BUSS adds that this **process** requires that: "the cells composing them (the tissues and organs)...limit their inherent potential for proliferation. The propensity for continued **self-replication** has been subjugated to the interest of the whole" (ibid).

This "subjugation" is in fact a bottom-up up-building of an harmonized **hierarchy** and a functional **network**, through reciprocal **constraints** within a shared **environment**.

The complex nature of these somatic ecology processes is also described by J. HOFFMEYER (1995, p. 16-25)

→ **Autogenic systems precursors; Dictyos-telium discoideum; Parallel distributed processing; Stigmergy; Swarm intelligence; Zero-system**

3114

SOURCE^{2) - 4) - 5)}

1. A fixed point that repels all the points in its neighborhood.

A source is the topological opposite to a **sink**. It acts as a kind of negative or anti-attractor.

2. A place or system in the **environment** wherefrom a system receives some specific **inputs**.

Some sources provide absolutely indispensable **resources** to the system, as for example the atmosphere for aerobic **living systems**. Other may provide it with merely useful **resources**, as for example some kinds of non basic foods.

Other sources may be downright noxious for the system, when it is obliged to absorb what they produce: this is the basic problem of contamination.

Systems need maintain a stable relation with their sources, according to their needs. A system which depletes some of its indispensable sources may find itself in danger if the **resource** becomes unable to regenerate at a sufficient rate.

Various systems may compete to obtain **resources** from the same source. This becomes

frequently a cause of **conflict**. Later on it may however lead to some form of negotiation between them and the setting up of some **regulator** whose **cost** is less than the global losses incurred previously.

Ecological **co-evolution** of **populations** of different species reflect the competition for the use of different sources, through ever-changing spontaneous **regulation**.

The **interrelations** between different sources and systems can be easily represented by qualitative **graphs** and also frequently quantified by appropriate **measurement**.

3115

SPACE (the abstract meaning)^{2) - 3)}

"Any abstract mathematical coordinata **framework** or **manifold**, of any number of **dimensions**, in which the **elements** of a **representation** can be ordered" (D. MacKAY, 1969, p.162)

3116

SPACE (the physical meaning)^{1) - 3)}

A. EINSTEIN wrote about two different concepts of space:

"a) space as a positional quality of the world of material **objects**

"b) space as container of all material **objects**.

"In case a), space without a material **object** is inconceivable. In case b), a material **object** can only be conceived as existing in space; space then appears as a reality which in a certain sense is superior to the material world".

EINSTEIN's synthetic opinion however is: "Both space concepts are free creations of the human imagination, means devised for easier comprehension of our sense experience".

He adds: "The victory over the concept of absolute space or over that of the inertial system became possible only because the concept of the material **object** was gradually replaced as the fundamental concept of physics by that of the **field**... that which constitutes the spatial character of reality is then simply the four-dimensionality of the **field**. There is then no "empty" space, that is, there is no space without **field**" (in M. JAMMER, 1957, p.XIV - XVI).

H. MINKOWSKI already in 1908 wrote: "Space by itself, and **time** by itself, are doomed to fade away into mere shadows, and only a kind of union of the two will preserve an independent reality" (in his lecture "Space and Time" - reproduced in "The Principle of Relativity" - Methuen, 1923, p.75, reedited by Dover).

And, as "there is no space without **field**", it becomes also obvious that **energy** and **matter**, by themselves also fade away as isolated concepts.

P. MANZELLI offers a different, but convergent, view of space: "... the space concept is an essential consequence of the **information/matter interactions**, that depend on the 'auto-organization' of the **dynamical processes** in the physico-chemical **transformations**" (1993, p.333).

Space, like **time**, **matter** and **energy** seems to be an aspect of a global frame for reality (EINSTEIN's field ?) that *our mind* fragments in its utmost effort to understand "the world there outside".

Via the **organization** of the brain **network**, as an **information processor**, these different notions could finally be parts of our constructed **conceptual autopoietic frame of reference**.

3117

SPACE MORPHOLOGY²⁾

R. THOM shows that the **structure** of geometrical space can be established: "In dimension 3, for example a cube, ... we have four types of points: the internal ones, those internal to a side, those on the edges and those on the vertices" (1991, p.117).

This can be generalized appropriately to spaces of any number of dimensions and gives an interesting insight about how our **abstraction frames** surge out of our empirical **perceptions**.

3118

SPACE PERCEPTION³⁾

BERTALANFFY observes that von UEXKÜLL discoveries about the selective **ambients of living systems** relativize "... forms of intuition, considered by KANT as a priori and immutable. The biologist finds that there is no absolute space or **time** but that they depend on the **organization** of the perceiving **organism**" (1962, p.74).

Indeed experiments and even daily experience "... prove that the space of visual and tactual perception is in no way Euclidian. In the space of perception, the coordinates are in no way equivalent, but there is a fundamental difference between top and bottom, right and left, and fore and aft. Already the **organization** of our body, and, in the last resort, the fact that the **organism** is subjected to gravity, makes for an inequality of the horizontal and vertical dimensions" (ibid).

Moreover "... **perception** of space is based on binocular vision, parallax, the contraction of the ciliary muscle, apparent increase or decrease in **size** of an approaching or receding **object**" (ibid., p.79).

Thus space (as well as **time**, **matter** and **energy**), while their existence is doubtless as neatly separated **frames**, are constructed by us as a useful conceptual **frame**, in correspondence with our biological nature.

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

I. SILVERMAN, for instance, observes: "Space is the medium in which **Energy** and **Time** expenditures are opposed" (1992, p.137).

3119

SPACE STRUCTURATION (Two dimensional)^{2) - 4)}

The subject was tackled by W. CHRISTALLER (1933 & 1937) and again by A. LÖSCH (1944).

L.F. RICHARDSON, in turn, studied it in an appendix to his "Statistics of deadly Quarrels" (1961, p.139-87), in relation to the influence on wars (foreign or civil) of **population** densities and **locations**.

He defined the notion of "**homoplasy**", i.e. the condition of a closed surface about as broad and as long as possible: "The geometric figure which satisfies completely the property of homoplasy is the circle. It is known, however, that a two-dimensional region cannot be divided into contiguous circles".

Thus, the search for homoplasy becomes the search for the best possible **contiguity**. As already discovered by CHRISTALLER, this is obtained by clustering space hexagonally. RICHARDSON found that 2-dimensional space can be thus partitioned in hexagonal cells in any extension and at any **level** by using the formula:

$$3K^2 - 3K + 1$$

...in which K must be an integer.

Moreover, any hexagonal grid can be fractalized with cells of $1/7$ th, or $1/7^2$ or $1/7^3$, etc. of the area.

The general rationale behind this is that hexagonal clusters express iso-pressure between human **populations** in territory occupation.

CHRISTALLER had also discovered that growing **density** of occupation tends to lead to the appearance of **population** (and services) concentration at the center of every hexagon.

This kind of **implosion** has been explained later by P. ALLEN et al, through dissipative structuration due to massive **inputs** of **energy**, thus adding a dynamic dimension to these **models** of space occupation.

RICHARDSON had however discovered that hexagonal grids could become deformed under some strain, as for example centrifugal or centripetal and gave formula for what he respectively called "central desert" and "central town".

This effect he called "conformal representation" which "allows the honeycomb **pattern** to be strained in all those manners which leave the **cells** almost regular hexagons but no longer all equal" (1961, p.154).

More recently, M. MARUYAMA observed that there is an inhibiting effect exerted by any **element** on **elements** of the same class, which leads to what he called "spacing". He adds: "Spacing contributes to **heterogeneization**" (1994, p.81).

This rule also seems to be valid for biological organisms and in interpersonal contacts (see for instance E. HALL's proxemic research, specially "intrusion distance" - 1959, 1966, 1977).

→ **Hexagonal space filling**

3120

SPACE SYNTAX²⁾

A theory of **space organization** as understood by its users, based on **rules** defined by easiest access from one point or place to another (B. HILLIER, 1996)

Space syntax can be easily represented by **graphs**. Such **models** are useful to modify and enhance general **accessibility** for example in urban **organization** or in roads **networks**. (See also M. HAMER, 1999)

→ **Hexagonal space filling; Occupancy rule; Pattern diversity; Polycentrism; Proxemics; Spacing**

3121

SPACESHIP EARTH¹⁾

"A concept/philosophy for **understanding** and considering the Earth as a spaceship with a limited life supporting system or as a finite, complex **ecosystem**" (UNESCO-UNEP Glossary, 1983, p.25).

In Spaceship Earth, "**survival** requires wise management of limited **resources** and harmonious human and **environmental relationships**" (Ibid).

This concept was introduced in 1966 by K. BOULDING and his short essay has been reprinted in various collections.

3122

SPACE-TIME (Relativistic causal structure of)²⁾

F. HEYLIGHEN comments: "The causal **structure** of space-time, determined by the requirement that causal **processes** be "enclosed" by the light cone, introduces an additional **redundancy** (determining a **topology** on space-time) and a higher-order **distinction** between **processes** inside, outside, or on the light cone while, at the same time, relativizing the **invariance** of the lower-order **distinctions** defining **simultaneity**" (1990, a, p.442).

3123

SPACING²⁾⁴⁾

In a **complex system**, the tendency of similar **subsystems** or **elements** to maintain a minimum **distance** between each others.

As graphically stated by M. MARUYAMA: "You would not build two post offices next to each other" (1994, p. 80). This **phenomenon** is a result of an **inhibiting effect**. Each element or subsystem needs sufficient **resources** within a reach that minimizes the **costs** of obtaining needed **inputs**.

→ **Ecosystem; Niche; Territory**

3124

SPAN²⁾

"The number of entities at the next natural lower **level** in a **hierarchy** which report directly to the entity whose span is to be identified." (T.F.H. ALLEN & T.B. STARR, 1982, p.277).

ALLEN and STARR explain: "... span is observer-defined by what he chooses as natural **boundaries**, that is, what he determines to be the next **boundary** inward or the next **level** down. Span is a matter of appearances, not of **ontological truth**, although appearances involving natural **boundaries** are often shrinking enough..." (p.278).

3125

SPAN OF A SYSTEM²⁾

The number of **subsystems** into which it is partitioned (H. SIMON, 1965, p.65).

SIMON comments: "Thus, a **hierarchic** system is flat at a given **level** if it has a wide span at that **level**. A diamond has a wide span at the cristal **level**, but not at the next **level** down, the molecular **level**" (p.65).

Moreover, SIMON observes that "Most physical and biological **hierarchies** are described in spatial terms... On the other hand, we propose to identify social **hierarchies** not by observing who lives close to whom, but by observing who interacts with whom. These two points of view can be reconciled by *defining hierarchy in terms of intensity of interaction*, but observing that in most biological and physical systems relatively intense **interaction** implies relative spatial propinquity. One of the interesting characteristics of nerve cells and telephone wires is that they permit *very strong specific interactivity at great distances*. To the extent that **interactions** are channeled through specialized **communications** and transportation systems, spatial propinquity becomes less determinative of **structure**" (p.65).

From a more dynamized viewpoint, one may visualize the system as creating the **field**, or even being the **field**.

3126

SPANISH SOCIETY FOR GENERAL SYSTEMS^{*}

→ **Sociedad Española de Sistemas Generales (SESSE)**

3127

SPECIALISTS AND SYSTEMISTS^{1) - 3)}

K. BOULDING stated clearly the necessary relation between the "specific" and the "general": "somewhere between the specific that has no meaning and the general that has no content there must be, for each **purpose** and each **level of abstraction** an **optimum** degree of generality".

Already in 1922, A. BOGDANOV wrote: "No specialist can live completely and solely within his speciality; as a result of contact with other people his **knowledge** and experience inevitably go beyond its **boundaries**" (1980, p.17).

However, still now very severe misunderstandings do exist between specialists and so-called "**generalists**".

Many systemists view specialists as narrow-minded professionals, unable to get out of their own limited field, to understand specialists in other areas and to collaborate usefully in so-called "**multi-, or interdisciplinary**" groups to search for satisfactory solutions for complex **issues** or global **design**.

Conversely, many specialists view systemists as inconsistent Jacks of all trades, meddling uselessly with subjects about which they lack real **understanding**, or even sufficient **knowledge**.

Such a controversy seems senseless.

In our days, nobody can be useful if not specially trained and competent in some limited field. Any good systemist must *also* be a good specialist in some specific field.

However, any responsible specialist may not anymore limit her/himself to the search of some unilateral and narrow solution to some fragment of a problem, risking to create more problems in the **process**.

The true responsibility of systemists is to create a (**transdisciplinary**) **meta-language** of concepts, **methods** and **models**, directed to the general **understanding** of **interconnections** between fields, and to discuss this **meta-language** with the more open-minded specialists, in order to make it more complete and useful.

Conversely the true responsibility of specialists is to abandon the "that is not my matter" attitude, in front of some out of their field consequence of their work, and to accept the **dialogue** (or "multilogue"!) with the systemists, eventually correcting some oversimplifications or unsatisfactory pseudo-general concepts, **models** or **methods**.

→ **Clumpers and Splitters**

3128

SPECIALIZATION through competition¹⁾

Antagonisms between systems are frequently transcended into specialization in a more complex one, in which the antagonists are submitted to, or have accepted, reciprocal limitations.

Rivalries are transformed into **regulated** internal countervailing **feedbacks** which imply, if not **cooperation**, at least reciprocal tolerance.

Specialization can be **functional** or **structural** (as for instance in geographical sectors).

The enhanced **heterogeneity** within the **complex system** gives it a better capacity for **adaptation**.

3129

SPECIFICITY PRINCIPLE (MÜLLER's Law)^{1) - 3)}

There are as many unitary **informations**, qualitatively different as there are different **receivers** units

The groupings, in different ways, of these different **informations**, give their meaning to outside **events**.

3130

SPECTRAL ANALYSIS²⁾

A mathematical technique which permits the discovery of superposed **frequencies** in a curve.

As many different **frequencies** can be made to appear strictly by mathematical treatment, spectral analysis must be used with care.

K. BOULDING for instance, observes that economists have given scant attention to the underlying **cybernetic regulations** in economic **processes** and that: "Perhaps as a result of this failure to take a significant intellectual tool simply because (they) have not made it themselves, economists seem virtually to have lost interest in the theory of **fluctuations** and what work has been done in this has been of an extremely mechanical nature, using for instance, spectral analysis, which is an elegant way of detecting probably nonexistent **cycles** and throws no light on the real **structures** and **processes** which underlie **fluctuations**" (1972, p. 86)

The technique is also known as "**Fourier analysis**", "**Frequency analysis**", or "**Harmonic analysis**".

3131

SPECULAR INTERACTIONS³⁾

J.L. VULLIERME states: "The social composition of individual **behaviors** depends directly from the cognitive reference that each individual makes on himself; but this reference, in turn, necessarily passes through a reference to the way in which others refers themselves to him."

"This kind of mirroring – from here the term "specularity", from "speculum" latin for mirror – is the condition for possible objective **modelization**" (1990, p 153).

→ **"ROBOTS (social)"**

The so-called "objective **modelization**" is thus an intersubjective one, obtained by **consensus** and through a **permanent process** of consensuality. Moreover, this **process** is so automatic as to have remained practically inconscious until the 20th. Century (with some exceptions, as for example, BERKELEY).

The specular **interactions** are obviously an important mechanism of **organizational closure** and **self-organization**.

VULLIERME emits this interesting opinion: "... if some day, truly thinking artificial **machines** do appear, they will necessarily be socialized **machines**, i.e. **machines** able to communicate with others, to construct their **self-reference** through cross referencing with other; and not **machines** able to modify themselves only because they would be previously apt to modelize **objects**" (1990, p.153).

→ **ROBOTS (Social)**

3132

SPECULARITY⁴⁾

"A mode of **complex organization** (verified in anthropo-social systems) whose **dynamics** consists of a tangle of internal **modelizations**" (J.L. VULLIERME, 1990, p.147).

VULLIERME states: "**Complexification** has become an imperative in social sciences, as shown by the "specular theories".

"These theories start from the hypothesis that all anthropo-social **organizations** are based on the "specular **interaction**" of their members, i.e., a crossed cognitive **interaction** (see: "**Cognitive rings**"), such as any **agent** refers to himself only through **reference** to the way that others agents refer themselves to him" (p.148).

Thus the **behavior** of all **agents** is derived from these cross-references.

It seems moreover that:

1. this way to social **complexity** exists also in animal societies, as shown for example by Th. SEELEY's studies on honeybees (1989), and the one of SUSSMAN on the social phase of **Dicystostelium discoideum** (1964).
2. there exists also an indirect way of reciprocal social conditioning, by **observation** of the material results of the **activities** of other members even if these are absent, or even if they already disappeared (see **stigmergy**).

3133

SPEECH ACT¹⁴⁾

Any utterance that can be considered as an **action**.

Examples are: "I warn you" - "I promise you", or if you are a priest: "I marry you". This concept was developed by J. AUSTIN (1962).

Its systemic interest lies in the common **tacit knowledge** by the concerned participants of the relevant "**class** of communicative **actions**".

3134

SPILLOVER COST→ **Commons; Effects (side)**

3135

SPILLOVER EFFECTS²⁾

Also called "**Perverse effects**" by some french sociologists

→ **Effects (Side)**

3136

SPIRALITY²⁾

The characteristic **recursive process** as it appears in the **time dimension**.

The concept of spirality is more adequate that the **circularity** one, in accordance with HERACLITUS saying that we never swim twice in the same river.

It also reflects in a more satisfactory way the dynamics of **fields**.

→ **Helix, Toroid**

3137

SPLITTERS and clumpers→ **Clumpers and Splitters**

3138

SPREADTHINK⁴⁾

A kind of conceptual **pathology** of **groups** unable to reach any "genuine **consensus**, or even majority view toward component aspects of a **complex issue**" (J. WARFIELD, 1995, p.IV).

WARFIELD dedicates a full chapter to the important concept reflected by this neologism, used to explain ineffective thinking in **groups** (p.73-87).

He states that this collective condition is generally neither recognized nor compensated for, and proposes a **method** to correct this type of **situations**.

He writes: "Spreadthink can be viewed as a short name for the content of these two Laws of **Complexity**".

"- The Law of Inherent Conflict – which asserts that no matter what the **complex issue** and no matter what the **group** involved, there will always be significant **conflict** in interpreting what is important in resolving that **issue**.

"- The Law of Diverse Beliefs – which asserts that at the outset of an investigation of a **complex issue**, members of the **group** will have quite diverse beliefs about the **issue**" (p.75)

He explains spreadthink as a result of four other laws, namely:

- The Law of Limits: according to which no single individual is able to obtain an all-embracing **information** and **understanding** about a **complex situation**.

- The Law of Organizational Linguistics "which relates to the inadequacy of organizational **language** to supply the conceptual terminology in which to couch a proper viewpoint of a **complex situation**" (This surely means "of any *specific* organizational **language**")

- The Law of Structural **Underconceptualization**, a result of the use of **methodologies** only appropriate for ordinary simple **situations**.

- The Law of Requisite Saliency which asserts that people find difficult to organize well their ideas around the most relevant aspects corresponding to a specific **situation**.

WARFIELD shows how **Nominal Group Technique and Interpretive Structural Modeling** can be used to discover, and correct spreadthink in order to define an **evaluation** of any **situation** satisfactory for the whole **group** of participants.

3139

SQUEEZING EFFECT^{2/4)}

The pressure of some environmental **factor** on a number of loose **elements**, generally of the same kind.

The general result of the effect is to transform the loose elements into a more or less organized and structured **group**, with some collective **behavior**.

The environmental pressure can be of many different kinds, as in the following examples:

- the decrease of food disponibilities which induces the social state of the amoeba **Dictyostelium discoideum**
- the pressure exerted by some predator on a more or less scattered group of preys
- some collectively perceived danger (fire, gunfire) which produces a panic in a human **crowd**.
- the general underlying factor is the shortening of the distance between the elements, which enhances the possibilities for new and closer **relationships** through a stronger reciprocal **perception**. Squeezing effects seem to be closely related to the appearance of all kind of **languages** (biophysical, biochemical, gestural or spoken) and seem to be the main root of possible further **cooperation**.

→ **Congeries; Crowding effect; Effect (Herd); Effect (Mass); Effect (Positional)**

3140

ST.GALLEN MODEL¹⁾⁵⁾

A view of **management** based on the idea that the business **organization** is similar to a living **social system** (Adapted from F. CAPRA, 1997, p. 76)

This model was evolved by H. ULRICH at the University of St. Gallen in Switzerland (1984), where this work is still forwarded now by Prof.

M. SCHWANINGER (1998, 2001) and his colleagues

It is to be compared with MILLER's **Living Systems taxonomy**, specially at the complexity level of the **Group**, the **Organization** and the **Community**.

This concept includes "many ideas from biology, **cognitive science**, **ecology**, and evolutionary theory". CAPRA notes that "these developments gave rise to the new discipline of "systemic **management**" (Ibid, p. 76)

3141

STABILITY¹⁾

The ability of a system to maintain its **equilibrium** or regain it if temporarily perturbed.

With the exception pictured by a ball resting in the deepest of a well, stability is the result of a **process**. In effect, it depends necessarily on some **cybernetic mechanism of stabilization**.

In K. BOULDING words: "Stability has to be seen as a subspecies of **change**" (1956, p.68). It should never be confused with immobility.

Stability in systems is related to dynamic **equilibrium** and implies **fluctuations** of the systemic **processes** within defined **limits**, with the help of **negative feedbacks** to compensate excessive accelerations or **amplitudes** and **positive feedbacks** to compensate undue slowing down or reduced **amplitudes**. This is **control** by **compensated** or **countervailing regulation**.

"Stable" is thus very far to mean "static". As observed by E. JANTSCH, systems of high **complexity** trade part of their stability for richness in **adaptability** (1975, p.52).

A stable system is thus a **controlled** one – either naturally or artificially and in G. WEINBERG's words: "implies **limits** to the **disturbances** that the system is supposed to withstand" (1975, p.230). But the exact determination of this **level** of admissible **disturbances** is in itself a difficult and crucial matter (Ibid).

T.F.H ALLEN and T.B. STARR explain: "There are several definitions involved:

"a) *Sensu lato*, the general display of persistence in both **structure** and **patterns of behavior**. Here **resilience** is one aspect of stability.

"b) *Sensu stricto*, specifically excludes **resilience** as part of the definition and refers only to the rapidity with which the **equilibrium** is re-established when displacement from the **equilibrium** occurs. Generally systems stable in this sense resist the influence of outside **disturbance** rather than accommodating the influence once it has had its effect.

"c) **Structural stability**, the capacity of a system to display generally the same **emergent behavior** despite **changes** in the interrelationships between its **parts**. In case of an

equation, **structural stability** would be represented by the persistence of general **patterns of behavior** despite **changes** in the equation **parameters**" (1982, p.278).

→ **instability, metastability, and ultrastability**

3142

STABILITY AND COMPLEXITY ¹⁾

Is complexity a favorable or unfavorable factor of stability in systems?

Any very complex system (For ex. an **ecosystem** or a **sociosystem**) offers many alternatives for **adaptations** to environmental **disturbances** or, in terms of ASHBY, a high degree of **variety**.

However this **adaptability** depends on the system's **dynamics**. A very static system has scarce possibilities to use any available **variety**.

On the other hand complexity should not be confused with the excess of redundant and ill-connected **parts**, which use up the systems **resources** for their self-maintenance without enhancing its **adaptability** and can even reduce it.

→ **Conglomerate**

3143

STABILITY AND RESILIENCE ¹⁾

A very high stability is advantageous for a system only if its **environmental** conditions themselves are very stable, since in this case, it will likely be able to maintain its **processes** within their **limits**.

However, when it may have to confront strong, ample and frequent **disturbances**, resilience is a great vantage. In such case, by admitting the risks and **costs** of crossing **thresholds** into other **domains of attraction**, the system may significantly enhance its **survival** potential, even in quite unfavorable conditions. As stated by L. SLOBODKIN: "... **evolution** is like a **game**, but a distinctive one in which the only payoff is to stay in the **game**" (1964).

These **trade-offs** between stability and resilience are of universal interest for **organisms**, species and human **organizations**.

3144

STABILITY AND WHOLENESS ¹⁾

W.R. ASHBY emphasizes that stability (as he defined it: i.e. "dynamic stability"):

"... in no way implies fixity or **rigidity**. It is true that the stable system usually has a **state of equilibrium** at which it shows no **change**; but the lack of **change** is deceptive if it suggests **rigidity**: if displaced from the **state of equilibrium** it will show active, perhaps extensive and complex, movements. The stable system is restricted only in that it does not show the unrestricted **divergencies of instability**" (1960, p.55-6).

This leads him to relate stability to **wholeness**, in the following way:

"An important feature of a system's stability (or **instability**) is that *it is a property of the whole system and can be assigned to no part of it*. The statement may be illustrated by... the practical construction of the thermostat. In order to ensure the stability of the final assembly, the designer must consider:

(1) The effect of the temperature on the diameter of the capsule, i.e. whether a rise in temperature makes the capsule expand or shrink.

(2) Which way an expansion of the capsule moves the lever.

(3) Which way a movement of the lever moves the gas-tap.

(4) Whether a given movement of the gas-tap makes the velocity of gas-flow increase or decrease.

(5) Whether an increase of gas-flow makes the **size** of the gas-flame increase or decrease.

(6) How a increase in **size** of the gas-flame will affect the temperature of the capsule.

Some of the answers are obvious, but they must none-the-less be included. When the six answers are known, the designer can ensure stability only by arranging the **components** (chiefly by manipulating (2), (3) and (5) so that as a **whole** they form an appropriate combination. Thus five of the effects may be decided, yet the stability will still depend on how the sixth is related to them. *The stability belongs only to the combination; it cannot be related to the parts considered separately*" (1960, p.56).

and: "The fact that the stability of a system is a property of the system as a **whole** is related to the fact that *the presence of stability always implies some co-ordination of the actions between the parts*. In the thermostat the necessity for **co-ordination** is clear, for if the **components** were assembled at random there would be only an even **chance** that the assembly would be stable. But as the system and the **feedbacks** become more complex, so does the achievement of stability become more difficult and the likelihood of instability greater" (1960, p.57).

One may wonder about the implications of this last sentence for the contemporary human systems (natural and artificial), which become evermore complex.

3145

STABILITY (Asymptotic) ^{1) - 2)}

The tendency of a system towards a final **state** of absolute stability.

Such a **process** is characterized by the progressive damping with **time** of adaptive **fluctuations** within narrowing **limits**. Absolute stability is never reached (not even through *rigor mortis*) because it results in immediate end of **coherence**, the consequent **breakdown** of the system and the swift dispersal of its **elements**.

This is also true in ecological systems, as shown by Ch WALTER in a critical study of the LOTKA and VOLTERRA prey-predator equations (1954, p.215-217).

Asymptotic stability as a **process** is possible only for some **time**, until some basic **function** of the system undergoes a **disturbance** that throws it out of its stability conditions.

3146

STABILITY (Dual) ²⁾

A form of stability consisting of two different **zones** of stability, or **phases**, separated by a **discontinuity**.

Also known as bi-stability, this condition is proper to numerous physical, biological and ecological systems, and can be also found, at least in a metaphoric sense, in economic and **social systems**.

Bi-stable systems "jump" from one state to the other through a "**catastrophe**".

3147

STABILITY (Dynamic) ^{1) - 2)}

Property of a system that maintains its **structures** and **functions** within well defined and relatively narrow **limits** during a long period of **time**.

K. BOULDING observes: "... it was an economist, Paul SAMUELSON, in his *Foundations of Economic Analysis*, who gave the first clear exposition of the principle that **equilibrium** of any system has to be derived from its dynamic **path** and that we could not find out about the stability of an **equilibrium** from an inspection of the equations of **equilibrium** alone... **Equilibrium** is simply a dynamic **process** in which the dynamic **path** of the system leads to a reproduction in successive **states** of some initial **equilibrium state**. "Staying the same" is simply a special case of "changing" (1972, p.81).

J.de ROSNAY comments: "To maintain itself is to endure. **Negative feedbacks**, by controlling divergent positive ones, tend to stabilize a system and to allow it to last. The system is able to regulate itself.

"To mix stability and **dynamics** may see paradoxical. In fact this link expresses that the **structures** or **functions** of an **open system** remain **self-similar** in spite of the permanent renewal of the systems **components**. This persistence... is dynamic stability. It is found in the **cell**, the **living system**, or the flame of a candle.

"Dynamic stability is the result of combination and readjustment of numerous **equilibria** attained and maintained by the system, as for example the **equilibrium** of internal **medium** of the **organism**... These equilibria are thus dynamic. This imposes however a **distinction** between equilibrium between forces and **equilibrium** between **flows**" (1990, p.117).

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

Homeostasis as studied by W. CANNON (1963) is dynamic stability in **living systems**.

3148

STABILITY (Dynamic) and CONNEXITY ¹⁾

H. SIMON states that "Interesting results have been obtained showing that dynamic stability of a large class of **complex systems** depends on their **components** connexity: For the lesser **levels** of connexity, they will be stable, but upon a given **level**, they will suddenly become unstable. This **phenomenon** was demonstrated by simulation by GARDNER and ASHBY and later on, analytically proved by MAY".

MAY's result "shows that, among highly interconnected systems, only some quite specific systems will be stable. Because unstable systems have a fleeting existence only, we must expect that many of the effectively observed systems will offer relatively low degrees of connectivity among their components" (1990, p.137-138).

Cohesion rests on connexity. However, while insufficient connexity implies scattering and eventual dislocation of the system, an excess of connexity provokes its freezing. This problem, specially in the very huge systems, seems related to slowdown in **communication** and over-saturation in **communication channels**.

3149

STABILITY (Dynamic) of a flame ²⁾

W. KOHLER writes: "Life has sometimes been compared to a flame (e.g. ROUX, 1914, p.17,p.79). This is more than a poetical **metaphor**, since, from the point of view of **function** and energetics, life and flame have actually much in common. The flame, say a candle, is a **steady state**. The continued existence of this **state** involves a continual supply of potential **energy** which the flame receives as "food" through the wick and as oxygen from the air...

"We light a candle with a match. On the wick there appears at first a tiny flame. This flame grows spontaneously until it attains a maximum **size** and at the same time a certain shape, which then remains unaltered.

"(When) the flame begins to grow... **gradients** are set up both for the food and the oxygen. The flame begins to grow, and these **gradients** increase correspondingly... But there is a **limit** to this **process**. When a certain **size** and a certain maximum of combustion have been reached, any further **growth** of the flame would lead to a higher demand than is compatible with the possible speed of oxygen diffusion from the surrounding air and with that of the food-stream which passes through the wick" (1969, p.34).

The **energy** consumption thus settles at the maximum compatible with the system's nature (in this case *physical*) in relation to the environmental conditions. In an atmosphere of pure

oxygen, this maximum would be higher, but if we place the flame within some enclosure, it burns up the oxygen and dies out. **Dynamic stability** is thus a **transformation** mode of **energy** and is not specific to **living systems** only.

3150

STABILITY (in the sense of LAGRANGE) ^{2) - 5)}

A stability characterized by a strict **periodicity** of the **trajectory**.

This means that **frequency** and **amplitude** must be conserved.

3151

STABILITY (in the sense of LIAPOUNOV) ^{2) - 5)}

Basically, LIAPOUNOV's stability implies that variations in the **initial conditions** do not change the **qualitative behavior** of the system, i.e. allowing for definite **phase transitions** between a **limited** number of qualified possible **states**.

J.L. CHABERT and A.D. DALMEDICO write: "POINCARÉ considered also another concept of stability, which was made clearer somewhat later on by the Russian mathematician LYAPUNOV, and which concerns the difference between a **periodic trajectory** and the neighbouring ones: if the difference diminishes the **trajectory** is stable. The solutions are stable or unstable in relation to certain coefficients which typify them, the "characteristic exponents" (1991, p.570).

These are known as "LYAPUNOV exponents" and defines **trajectories** which maybe **asymptotic**, **periodic** or **chaotic**.

3152

STABILITY (in the sense of POISSON) ^{2) - 5)}

A stability characterized by "the return of a point after some **time**, if not at its initial position, at least to a position as close as one wishes to this initial position" (1991, p.570).

This implies that the **trajectory** should never cross a "no-return" **threshold** of **instability** and that the system should never become **dissipative**.

3153

STABILITY (Levels of) ^{1) - 2)}

No stability is absolute. However, **short**, **medium** and **long term** stabilities can be distinguished in many cases. Of course, **short**, **medium** and **long term** should be defined according to the nature of the system and its **processes**.

Higher levels of stability **embed** shorter ones as their **limit**. As stated by L. DOUGLAS KIEL: "This **understanding** requires a rethinking of the purposes of **forecasting**. Perhaps a more prudent approach to **forecasting** then, should

focus on **forecasting** "symmetry breaking" **events** when existing **structures** break down generating extreme **uncertainty** as to **structural** and **behavioral** outcomes" (1975, p.36).

A good application of this different **forecasting** technique is the chartists analysis of stock markets **trends**. (which does not imply that chartists necessarily understand the rationale of this technique!).

3154

STABILITY (Local) ^{1) - 2)}

The characteristic of a system in which some **parts** are remaining constant at some times.

This concept belongs to W.R. ASHBY (1960, p.171-83).

Any **concrete system** must necessarily present a number of **parts** or show **subsystems** which maintain their stability during various **periods** of **time**. While this stability is generally **dynamic** (i.e. **oscillating**), the **fluctuations** are so slight or slow that they do not notably affect other **subsystems**, thus ensuring the continuity of the system as a **whole**.

Local stabilities allow for the upbuilding of the system's **structures**.

→ **Frozen cores**

3155

STABILITY (Lotka-Volterra model of) ²⁾

C. HOLLING evaluates this **model** in the following way: "... the familiar LOTKA - VOLTERRA **model** includes the simplest and least realistic (terms), in which death of prey is caused only by predators, predation is a **linear function** of the product of prey and predator **populations**, and **growth** of the predator **population** is linearly proportional to the same product. This **model** generates neutral **stability**..., but the assumptions are very unrealistic since very few **components** are included, there are no explicit **lags** or spatial **elements**, and **thresholds**, **limits** and **nonlinearities** are missing" (1976, p.75-6).

In any case, LOTKA and VOLTERRA's work has been a pioneering one. Its critique led precisely to the study of the aspects emphasized by HOLLING and contributed to the emergence of the **concepts** of **attractors**, **stability** and **chaos**, as well as to a better **understanding** of the nature and importance of **nonlinearity**.

3156

STABILITY (Meta-) ²⁾

→ **Metastability**

3157

STABILITY (Neutral) ²⁾

Situation of a system which "... rests at any perturbed condition without tending to return to, or diverge further from the original **equilibrium point**" (J. MILSUM, 1968, p.47).

While this is the case of a marble on a flat surface, neutral stability generally would be quite a unnatural condition in any **complex system**.

3158

STABILITY (Parameter change and)²⁾

According to W.R. ASHBY: "...because a **change** of parameter value changes the **field**, and because a system's stability depends on its **field**, a change of parameter value will in general change a system's stability in some way" (1960, p.77).

"Change of parameter value may result in any **change** which can be produced by the substitution of one **field** for another: stable systems may become unstable, **states of equilibrium** may be moved, single **states of equilibrium** may become multiple, **states of equilibrium** may become **cycles**, and so on...

"...the **relationship**... is reciprocal: in a **state-determined** system, a **change** of stability can only be due to a **change** of value of a parameter, and **change** of value of a parameter causes a **change** in stability" (Ibid.p.78).

3159

STABILITY (Poly-)^{2) - 4)}

"A stability involving many alternatives and sometimes only temporary **equilibria**" (K. KRIPPENDORFF, 1986, p.58).

KRIPPENDORFF explains: "(it) is characteristic of systems involving many weakly interacting **components**. When systems are joined to form larger **wholes**, **communication** among them tends to have the effect of disturbing each other's individual **equilibria**. The **equilibrium** of the **whole** is not merely selective of, and may not even coincide with the **equilibria** of its **parts**" (Ibid).

It is now understood that, as **simultaneous events** in different **parts** of the system cannot propagate instantaneously to the **whole**, local **desequilibria** can never become completely settled.

The effects of poly-stability are seldom understood by managers of economic or political systems, which explains that they in many cases merely try to "catch up".

3160

STABILITY (Poly-) by multiple LOCALIZATIONS²⁾

W.R. ASHBY states: "...in a large polystable system, a whole reaction will be based on **activities** that are both numerous and widely scattered...

"...so a reaction based on numerous and widely scattered **elements** will tend to have more **immunity** to localized injury than one whose **elements** are few and compact"(1960, p.182-183)

ASHBY arrived to this conclusion in relation to LASHLEY's experiments about **memory** traces in the **brain**. This kind of polystability by non exclusive **localisation** may explain how a near complete mental rehabilitation is frequently possible after a cerebral haemorrhage, when not too massive. The same **behavior** is obvious in any human (or insect) society repairing damage after some destructive event.

3161

STABILITY STRATA²⁾

According to E. LASZLO, it appears that **energy flows** "have intrinsic stability in specific **configurations**" (1974, p.207).

He recognizes the following stability strata: atoms, molecules and crystals, macromolecules aggregates, **cells**, multicellular **organisms**, self-contained coordinated **populations (ecosystems)**.

We would add **social systems**, maybe even in the very basic sense that every stability stratum corresponds precisely to the shaping of social **links** within **wholes**.

The concept of stability strata also appears in C. BRESCH's more recent work (1987), and at least in an implicit way in various other authors, as for example J. MILLER's **levels of organization in living systems**.

3162

STABILITY (Structural)²⁾

"The capacity of a system to maintain the same essential **patterns of behavior** despite some modification in the structural **interrelations** between the systems **parts**" (T.F.H. ALLEN & T.B. STARR, 1982, p.278).

The concept of structural stability was introduced in 1937 by the Russian mathematicians A. ANDRONOV and L. PONTRIAGIN. It led and is still leading to considerable developments in the **topological** study of the **complex systems stability**, as for example **catastrophe theory** (THOM and ZEEMAN), the various types of **attractors**, and **deterministic chaos**.

As stated by L. LÖFGREN: "A system is structurally stable if the **topology** of its **trajectories** is preserved under sufficiently small **perturbations**" (1974, p.78).

For K.B.DE GREENE: "A **function** or system is structurally stable if such qualitative properties as numbers and kind of **critical points** and **basins of attraction** remain unchanged after a sufficiently small **perturbation**" (1990, p.54).

Small modifications correspond mostly to small **perturbations**. Structural stability is compatible with more or less **periodic changes of state**, i.e. with **ergodicity**.

According to S. DINER: "A structurally stable **dynamic system** is... a **topologically** stable system, i.e. a system whose **phase portrait** undergoes few modifications and remains topologically **self-similar** under the influence of

lesser **perturbations** in its movement equations...; (it) maintains its essential qualitative properties when affected by a slight **perturbation**" (1992, p.360).

This is the case for merely local **instabilities**.

To the ALLEN and STARR's definition and LÖFGREN's comment, which correspond to confirmed stable systems, one should aggregate the following comment by K.DE GREENE: "... structural stability in **dissipative-structure** theory refers to the **response** of the system to the addition of new **elements**" (1988, p. 291).

And: "The structural stability of any existing **deterministic system**, potentially capable of **evolution**, is continually tested by both internal and external (**random noise**) **fluctuations**" (DE GREENE, 1994, p.14). On the contrary: "The system is structurally unstable if mutations (genetic, scientific, technological, "great persons" – my terms) can multiply and take over and modify system **processes**" (Ibid).

R. ROSEN sees a practical use for the concept: "Structural stability is a general **framework** for comparing one **description** of a **class** of **objects** against another **description**, usually in terms of measures of **closeness**" (1991b, p.480).

3163

STABILITY (Struggle for)^{1) - 4)}

By its own nature, any system tends to remain within a defined stability **boundary**, which ensures its **homeostasis** and permanence, as long as no basic **change** in its **environment** throws it forcefully out of its **domain of attraction**.

However, as noted by C. HOLLING, **human systems** (which are increasingly destabilizing natural ones) must also increasingly: "... learn to live with **disturbance**, live with **variability** and live with **uncertainties**" (1976, p.91). This is the price to pay for **survival**.

We must accept that we are moving away from **homeostatic** stability and that the more we move away from it, the more potentially dangerous the **situation** of our systems, and the more difficult to turn back toward "classical" stability.

The struggle for stability implies for our **dissipative** and **emergent** systems, the search for a higher **level** stability, maintaining **resilience** by creating the possibility to switch, when needed, from one **domain of attraction** to another, within a blown up global stability **domain**.

A typical case where such ideas should be applied is the necessity to design alternative **strategies** in our fight against agricultural or pathological pests.

3164

STABILITY (Ultra-)→ **Ultrastability**

3165

STABILITY CONDITIONS¹⁾

Stability being a basic need for complex dynamical systems, a good **understanding** of stability conditions is very important.

Systems may resist destabilization in different ways:

1/ By the use of internal devices as for example:

- **regulators** and **controls** which adapt the system to the environmental variations (in a more or less statistical way)
- **redundancy**, which may allow one **component** or **subsystem** to replace another one, not able to function correctly
- **variety**, which offers to the system the possibility to select a specific response within a number of possible ones.

2/ By some **pre-adaptation** to a definite **environment** specially favourable:

- By avoiding excessive **specialization** in order to be able to adapt itself to different types of **environments**
- By acquiring the capacity to modify the **environment** in a way better suited to its needs.

All these conditions aim at the **maintenance** of the **identity** and permanence of the system. In the case of giant **fluctuations** and **dissipative structuration**, stability is irretrievably lost, but may be recovered for the benefit of the newly structured system which will possibly replace the former one.

3166

STABILITY MARGIN^{1) - 2)}

The values comprised between the uppermost and lowest **fluctuations thresholds** of some **parameter** critical for the **survival** of a system.

ROSENBROCK and Mc MORRAN, quoted by B. PORTER state, for instance: "... an essential requirement for most industrial **control systems** will be that **changes** of **loop gains**, between zero and the design values and in all combinations, should leave the system with an adequate stability margin" (1976, p.227).

As observed by these authors "... **optimality** does not insure this" (Ibid). (**Optimality** being understood, as it too frequently is the case, as maximality: productive **optimality** is not the same as systemic **optimality**).

Furthermore, a well managed system should ideally remain well within the **limits** of its stability margin, and avoid nearing to closely its **thresholds** of stability, in order to avoid too high **regulation costs** and sometimes very high risks.

3167

STABILIZATION²⁾

If a network is repeatedly disturbed by a regular "**stimulus**" or by a statistically homogeneous "**noise**", it will tend to set its **switches** so that it is less, rather than more, disturbed by it (W.R. ASHBY, 1960, p.5.).

"The property has been demonstrated on the **homeostat** (Ibid)..."

"It depends on the fact that **patterns** that are much disturbed by the **stimulus** will have a large **chance** of being disrupted, while those that are little disturbed will have only a small **chance** of being disrupted. Every **stimulus** or **noise** thus tends differentially to disrupt these **patterns** that are specially sensitive to it. The end-result is that the **machine** tends, if repeatedly stimulated, to become unresponsive to the **stimulus**" (1958, p.5).

ASHBY states: "In the cerebral cortex this **phenomenon** has been long known as "**habituation**". It is in fact not restricted to the cerebral cortex but can be observed in every tissue that is capable of **learning**" (p.5).

In human systems, a similar **process** leads to **routine-like behavior**.

3168

STABILIZATION after a bifurcation²⁾

Stabilization as described by ASHBY can be maintained only inasmuch as the perturbing **stimulus** does not lead to a giant **fluctuation** leading it **far away from thermodynamic equilibrium**, and the possible crossing of an **instability threshold**, leading to a **bifurcation**.

When the system is thus transformed, it may however reach a new **level** of stability.

Bifurcation points delimit in this way the stages of the system's **evolution** or **history**.

3169

STABILIZATION by COMPENSATION¹⁾

The stabilization of a **complex system**, that may be submitted to **chaotic dynamics** is a difficult endeavor.

R. ROSEN proposed to base such stabilization on a sufficient **knowledge** of the "... units of **function** and **homology** of **organization**, rather than on units of **structure**..."

"A corollary of this kind of viewpoint would be an insight into **mechanisms** by which **changes** of **state** of all kinds of systems could be directed (or **controlled**) through the external enhancement of the stabilizing or destabilizing forces inherent in the system (The inhibitory or excitatory factors respectively). Indeed, we can intelligently apply **controls** only when these factors and their dynamical **roles** have been identified, whether that be in human physiology (i.e. medicine), in **ecology**, or in socio-political or economic systems" (1974, p.173).

ROSEN himself admits that this "... is not a finished piece of scientific activity ready for applications, but only a program for such activity, a **strategy**" (Ibid).

Indeed, the possibilities of correction of **chaotic dynamics**, for example, remain still largely in 1997 a "terra incognita".

The alternative use of **inducers** and **repressors**, as observed by ROSEN, or in **cybernetic** terms, of combined **positive** and **negative feedbacks** are possible **mechanisms** for stabilization. But the main point remains the need for a sufficient **knowledge** of the *natural* dynamics of the interested system.

A closely related view is stabilization by **competition**, proposed by M. EIGEN and P. SCHUSTER within the frame of their **hypercycle model** (1979, p.VI).

3170

STABILIZATION STANDARD²⁾

"The **coded** instructions that indicate the **level** of **operation** to be maintained by the **programs** of a **controlled system**" (J.Z. YOUNG, 1974, p.299).

Standards may be embodied within the **program**, which is generally the case in **artefacts**. In natural systems, they must in general be learned. This is – at least partially – the case in biological and social **human systems**.

From a biological viewpoint, YOUNG notes that: "Hereditary standards are basically defined by the genetic **program** and then embodied in certain **parts** of the **brain**, for instance the hypothalamus".

3171

STAKEHOLDER^{1) - 4)}

"Any individual, **group**, **organization**, institution that can *affect* as well as *be affected* by an individual's, **group's**, **organization's**, or institution's *policy* or *policies*" (I.I. MITROFF and H.A. LINSTONE, 1993, p.141).

The authors comment: "The bigger, the more complex the **problem**, the more it is likely to involve a wider array of stakeholders" (p.141).

In a very general way, **issues**, **problems** and **situations** are considered within a quite restricted ring of stakeholders. This leads to quite negative consequences:

- the matter under consideration is insufficiently described and understood (**underconceptualization**)
- **decisions** are made or plans established which do not take in account some important aspects
- As a result, they may lead to new **problems**, or even the resurgence of the same ones
- Stakeholders who were not called to participate and feel harmed or simply do not understand the way matters are managed, become diffident or even hostile, do not lend their collaboration and possibly will sabotage.

Identification of the stakeholders is thus a previous and very important step in any **design, planning or decision making process** (see hereafter).

A most important characteristic of stakeholders is that they have **assumptions** about the **problem**, in many cases implicit and unconscious, or at least not overtly declared. It is necessary to make these **assumptions** appear clearly.

MITROFF and LINSTONE show how to establish **maps** of stakeholders **assumptions**, in a qualitative and quantitative way (p.144).

→ J. WARFIELD'S works.

3172

STAKEHOLDER ANALYSIS ^{1) - 4)}

A technique, described by M.C. JACKSON, that "asks each **group** to identify the key individuals or **groups** on whom the success or failure of their preferred **strategy** would depend. This involves asking questions such as : Who is affected by the **strategy**? Who has an interest in it? Who can affect its adoption, execution or implementation? And who cares about it? For the stakeholders identified, each **group** then lists what assumptions it is making about each of them in believing that its preferred **strategy** will succeed. Each **group** should list all the assumptions derived from asking this question of all the stakeholders. These are the assumptions upon which the success of the **group** preferred **strategy** or solution depends".

A second technique is "assumption rating": "For each other listed assumptions, each **group** asks itself:

- How important is the assumption in terms of its influence on the success or failure of the **strategy**.
- How certain are we that the assumption is justified" (1992, p.143).

→ "Assumptional analysis"; "Nominal Group Technique".

3173

STANDARD ¹⁾

A set of characteristics that define the normally accepted conditions, general **structures** and functionality of a system.

This applies to many different kinds of systems, as **artifacts**, natural or engineered controlling devices, behavioral **rules** of individuals, or human **groups**.

Evaluations of business practice and results, or financial situations are also submitted to specific standards.

3174

STASIS ^{2) - 5)}

1) The balance between various forces in **equilibrium**.

Stasis may appear at some **nodes** in permanently interacting **fields**. It could be the origin of stable **forms** and **homeostasis** (d'Arcy THOMPSON, 1916 – C. LAVILLE, 1950).

2) The state of **stability** reached by a species after a phase of swift **evolution**.

The concept has been introduced in paleontology and **evolution** theory by St. GOULD and N. ELDREDGE, who speak of "Punctuated **equilibrium** and macroevolution" (1993, p.223).

It seems to be a mere synonym for **homeostasis** (in **populations**). The authors write: "... stasis does not signify rock-hard immobility, but **fluctuation** of little or no consequence" (p.226).

The curious parallelism with PRIGOGINE's **theorem of minimum entropy production** from one side, and his **dissipative structuration** in **far-from-equilibrium systems** from the other, is striking and should be investigated.

3175

STATE (Critical) ²⁾

The state at which a specific **change** in the value of the **variable** produces a **discontinuity** (or jump) in a **step function**. (After W.R. ASHBY, 1960, p.91).

ASHBY gives as an example: "The critical state of an electric fuse is the number of amperes which will cause it to blow" (p.91)

There are also numerous mechanical and physiological examples of such jumps or **discontinuities** leading instantaneously to a quite different **state** of the system.

This type of events is akin to THOM's **catastrophes** but somewhat different to the critical state in **composite systems**.

ASHBY's critical state may be the harbinger of the systems **breakdown**, a totally irreversible **event**, while **criticality** in **composite systems** tends to self-reconstruction. However, even in strongly **integrated systems**, the **step function** may undergo periodic returns to the critical state.

3176

STATE DETERMINED ²⁾

The character of the future of a system whose present state and **behavior** are known.

Only simple **causal** and rigorously **deterministic** macroscopic (Laplacian) systems – which are the very rare exception – are strictly state determined. Practically neither the state, nor the **behavior** of a **complex system** are ever **perfectly** known. The concept, and the mathematics that describe it, are however useful within the brackets of **situations** considered stable in which both conditions are reasonably well known.

Ergodic systems are state determined only in a general stochastic sense... and beware of **deterministic chaos**!

3177

STATE EQUATION and STATE FUNCTION ²⁾

J.L. LE MOIGNE clearly distinguishes both, as follows: "A systems **state function** allows to understand its structural **dynamics**, while its **state equation** expresses its cinematics.

"The state equation implies the availability of the register of **parameter programs** of a given **structure**, which could be used as the framework for the **description** of the "Système Général"'s **trajectory**. The structural state **function** implies changing the frame of reference. (in this case) The **structure** is variable, as it is processed by the **fields** of variable intensity which affect the system. The frame of reference is now the environment, plastered with **morphogenetic fields**" (1977, p.172).

It would certainly be interesting to harmonize the concepts of state function with those of **organizational closure** (F. VARELA), **hypercycle** (M. EIGEN) and **slaving principle** (H. HAKEN).

3178

STATE (Initial) ²⁾

"The first state in a **line of behavior**" (W.R. ASHBY, 1960, p.20).

Starting from the initial state, "A **line of behavior** is specified by a succession of states and the **time-intervals** between them" (Ibid). This seems to be a simplified **deterministic** view.

However, initial states are generally complex, made of various (or numerous!) **interacting initial conditions**. J. CASTI observes that it is "impossible, practically speaking, to know a system's **exact** initial state; it is effectively uncomputable" (1994, p.114).

→ Garden of Eden

3179

STATE of a SYSTEM ¹⁾

"A recognizable condition of a system (G. PASK, 1961, p.117).

"The **set** of numerical values which the **variables** of a system have at a given instant" (W.R. ASHBY, 1960.2, p.16).

"The **set** of relevant properties of a system at a moment of **time**" (R.L. ACKOFF, 1972, p.84).

"A particular **pattern** of **relationships** existing among the **components** and the particular filtering condition of the **boundary**" (K. BER-RIEN, 1968,p.32)

Such generally **synchronic descriptions** – very complex in some cases – take their full sense only when repeated many times at successive instants, i.e. when becoming **diachronic**. Some features of the systems successive states may be conserved or may reappear periodically or irregularly, which comes to reflect precisely the systems identity: Multiple **stationary states** are possible.

While, according to H. PRAEHOFFER the present state "... represents a **memory** of the past of the system" (1991, p.292), such **memory** is frequently in part or totally illegible. The claim to be able to compute the future of a system "... just knowing the current state and the future **inputs**" (Ibid) seems to be in most cases a Laplacian fallacy.

The study of specific **transitions** from one state to a sequence of the other states through **time** is a common **method** to learn about the systems **behavior**. However, even the **observation** of only one instantaneous state may bring some **knowledge** of the system to the **observer**, as he usually relies on connectable **knowledge** obtained from previous experiences. In ASHBY's words: "If he sees two cogs enmeshed he knows that their two rotations will not be independent, even though he does not see them actually rotate" (1960, p.19).

Nevertheless ASHBY hastens to add: "... the unexpected sometimes happens; and the only way to be certain of the relation between **parts** in a new **machine** is to test that relation directly" (Ibid).

From a quite different viewpoint, E. LASZLO states: "The fact is that systems in the real world can exist in one of three types of states. Of these three, one is radically different from classical conceptions: it is the state **far from** thermal and chemical **equilibrium**. The other two states are those in which systems are either **in equilibrium** or **near it**" (1987, p.20).

The first of these two is the maximum **entropy** one,... when the system ceases to be a system. The other one is the common state of **dynamic stability** through **fluctuations** constrained within **limits**.

3180

STATE (Recurrent)²⁾

Situation of a system at a given **time** which is repeated at other instants.

Such a repetition is never perfect. It may be a result of the **invariance** of most **parts** of the system or of the reconstruction of a former **state**, through some **cycle** or **hypercycle**. For example the skeleton of a living vertebrate remains without significant **changes** at **macroscopic scale**. However, this is the result of a cyclical renewal of its **elements**.

Or, in a manufacture the state of the stock of raw materials or goods at some moment may be similar to an previous state, after use, sales and restocking.

3181

STATE SPACE²⁾

"Any n-dimensional space containing points representing the state **description**... of a system".

This formal definition has been given by M. TODA and M. SHUFORD (1965, p.26).

R. ROSEN clarifies the concept as follows: "The totality of all possible states of the system, meaning the totality of different aspects the system can assume *for us* at an instant of **time**, forms a **set** called the state space of the system" (1972, p.50).

T. F. H. ALLEN and T. STARR consider more specifically the **observer's** viewpoint and describe as follows the state space: "A **mode of description** of system **behavior** where, at each point in **time**, the system is described by the position of a point inside a space the dimensions of which are axes relating to the various systems attributes expressed as states (as opposed to derivatives)" (1982, p.278).

An interesting point: The state space is actually a **space-time frame**.

F. HEYLIGHEN gives a shortened definition of the state space: "The **set** of all possible states (of the system)" (1990a, p.426).

3182

STATE (Stable)²⁾

In a **dynamic system**, a state that can be maintained in general terms.

Absolute stability is a purely theoretical condition for any system, because it must always be capable of adapting to even slight **variations** of its **environment**.

A stable state is thus a state permanently constrained within a more or less narrow **channel of fluctuations** which do not impair its **structures** and **functions** in a noticeable way.

3183

STATE (Stationary)²⁾

"The state in which **inputs** are exactly equal to losses and in which **stores** remain stable" (Adapted from H.T. and E.C. ODUM, 1976)

This state is characteristic of **dynamic stability** and generally a result the system's own capacity to **regulate** its intakes and **outputs**. It is a near-synonym for **steady state**.

3184

STATE TRANSITION²⁾

The cross-over from one state to another in a system.

This cross-over can be strictly determined, probabilistic as in **ergodic systems**, or mean a deep change in the nature of the system, as in **chaotic dynamics**.

For the **purpose of modelling** along **reconstructability analysis** lines, G. KLIR introduces the **state-transition system**, "defined in terms of a **set** of overall states based upon a particular **mask** and a specification of conditions for transitions between these states. Epistemologically highest in this early version of the **hierarchy** is a **structure system**, which is defined as a **set** of interacting **behavior** or state-transition systems" (1991, p.345).

The **mask** represents the intentions of the **modelizer**, in relation to her/his specific interests.

3185

STATE-DETERMINED BEHAVIOR²⁾

G. PASK, reflecting ASHBY's views, writes: "A behavior is state determined if an **observer**, knowing the state at *t*, is able to predict the state at *t*+1 with certainty." (1961, p.28).

He rephrases it thus: "a behavior is state-determined if $X(t+1)$ depends in a unique fashion upon $X(t)$ and, in the **phase space**, this means that the path describing a state determined behavior does not **bifurcate**". (Ibid)

The contrary of state-determined behavior is thus **chaotic behavior**.

3186

STATES (Interconvertible)²⁾

The states of a system that may replace each other without affecting its global **stability**.

The concept, quoted by R. MARGALEF, was introduced by R. Mac ARTHUR (1955) (1980, p.62).

When numerous, interconvertible states increase the system's **stability**. This may generally be observed in **networks**, where **information** is widely distributed in many more or less **redundant circuits**, thus allowing for numerous equivalent states and avoiding the danger of **information** loss should one or even various **circuits** become disabled.

3187

STATIC or DYNAMIC VISION^{1) - 3)}

According to J.de ROSNAY "To the opposition between "analytic" and "systemic" we must add the opposition between static and dynamic vision".

He compares both in the following table:

Static Vision (simple systems)	Dynamic Vision (complex systems)
Solid	Fluid
Force	Flow
Closed system	Open system
Linear causality	Circular causality
-stability	-dynamic stability
-rigidity	-steady state
-solidity	-turnover
Equilibrium of forces	Equilibrium of flows
Type: Crystal	Type: Cell
Behavior of the systems	Behavior of the systems
-predictable	-unpredictable
-reproductabl	-non reproductable
-reversible	-irreversible"
(1975, p.112)	

Some of these items could be objected:

1. Generally speaking, there are no "simple" systems. What may be simple is some **function** in a system or some so-called "natural laws" as for example in Newtonian mechanics.

2. The opposition between **closed** and **open systems** is artificial. Any **concrete system** is open *and/or* closed according to its specific and timely necessity.

3. The **behavior** of **complex systems** is generally *more or less* predictable (or unpredictable).

4. As to **reversibility** of any **phenomenon**, it exists only in the *models*. The **2nd. Principle of thermodynamics** forbids it in real processes and systems.

3188

STATIGENESIS²⁾

The **stabilization phase** of a newly emerged type in an **evolutionary process** (W. SCHWEMMLER, 1991, p.152)

3189

STATIONARY PROCESS²⁾

A **process** of **energy transformation** that remains stable during a certain lapse of **time**.

W. KOHLER writes "...there are two classes of stationary processes, one with which a minimum, and another with which a maximum of **energy** is associated" (1969, p.67).

We thus should avoid speaking of *equilibrium* in the physical sense of the word.

Stationary processes are indeed an essential aspect of the **thermodynamics of irreversible systems faraway from equilibrium**.

The stationary process is closely linked to the **steady state**, which is its result.

3190

STATISTICAL SIGNIFICANCE^{2) - 3)}

The confidence degree sustained by a statistical **inquiry** which shows a sufficient **divergence** from purely **random effects**.

The matter is to determine what is a "sufficient **divergence**". On the borderline, some significant **effect** may seem to emerge, but may also remain somewhat (or largely) hypothetical.

On the other hand, statistical significance must be interpreted, i.e. given a *meaning*. At roulette, a 18/20 appearance of red would be statistically significant. But what does it mean? Has somebody "nursed" the wheel? which way? Why?, etc... These are systems problems.

From a systemic viewpoint, as stated by W.D. GROSSMANN and K.E.F. WATT: "... several **phenomena** of great recent importance are strongly dependent on the **behavior** of a very small proportion of all individuals, at the tails of frequency **distribution curves**. AIDS became a pandemic in part because of the atypical **behavior** of a tiny proportion of all individuals, not the average population-wide **behavior**" (1992, p.20). The authors give various other examples

of the shortcomings in the use of statistical average values (and of grossly misleading financial accounting (see "**Patrimonial accounting**").

This problem reflects an insufficient **understanding** due to excessively narrow **frames of reference** used to give significance to mere **data** and **information**.

3191

STEADY STATE²⁾

"A **time-independent state** of an **open system** in which all macroscopic quantities remain constant, although microscopic **processes** of the **input** and **output** of **matter** go on continuously" (I. BLAUBERG et al., 1977, p.47).

L.von BERTALANFFY describes the steady state in the following way: "An **open system** may attain (certain conditions presupposed) a **time-independent state** where the system remains constant as a **whole** and in its **phases**, though there is a continuous **flow** of the component materials" (1969, p.71)

"Time-independent" seems unfortunate **semantics**. (see hereafter)

BERTALANFFY adds however: "Steady states are **irreversible** as a whole, and individual **reactions** concerned may be **irreversible** as well. A **closed system** in **equilibrium** does not need **energy** for its preservation, nor can **energy** be obtained from it (NOTE: This is indeed the *isolated system*, perfectly disordered in its final state, as prescribed by the **2nd. principle of thermodynamics**).

"To perform work, however, the system must be, *not in equilibrium, but tending to attain it*" (Ibid).

(The German term for steady state, introduced by BERTALANFFY, is *Fließgleichgewicht*).

BERTALANFFY, in coincidence with PRIGOGINE, states: "a) Steady states in **open systems** are not defined by maximum **entropy**, but by the approach of **minimum entropy production**. b) **Entropy** may decrease in such systems. c) The steady state with minimal **entropy production** are, in general, stable. Therefore if one of the systems **variables** is altered, the system manifest **changes** in the opposite direction. Thus the **principle of LE CHATELIER** holds, not only for closed but also for **open systems**" (1969, p.78).

No steady state can be maintained without a continual expenditure of **energy**. Such **energy** must be obtained from the **environment** and is degraded as it is used by the system in order to maintain its **functions** and **structures**.

As observed by E. LASZLO a *steady state* system should be clearly distinguished from a *static* one.

In LASZLO's words: "... steady states are not **static** states, but ones which represent a **level**

of **equilibrium** between the internal **constraints** among the systems **components** and the forces acting on it from its **environment**. KATCHALSKY and CURRAN have shown that systems characterized by fixed internal **constraints** and exposed to unrestrained forces in their **environment** tend to produce countervailing forces that bring them back to the **stable states**, since the **flow** caused by the **perturbation** has the same sign as the **perturbation** itself".

This is a kind of generalization of **LE CHATELIER Principle** to **dynamic systems**. It implies that steady-state **behaviors** are **periodic**, or at least quasi-**periodic** (no **living system** could be static and survive).

LASZLO also proposed to replace "steady" state by "optimum" states, but he was not followed (1974, p.50).

BLAUBERG, SADOVSKY and YUDIN state: "Under certain conditions an **open system** may reach the steady state, as opposed to a **closed system** which, left to itself, *must* reach the state of **equilibrium**" (1977, Ibid).

However some caveats are required:

1/ **-Equilibrium** is static or dynamic. A static **equilibrium** would imply a total absence of movement, at least at the **observation level**. A **dynamic equilibrium** admits **fluctuations** around an average **level**.

2/ **-A steady state** is possible only in an **open system** (which admits **flows** of **inputs** and **outputs**). As to the "**closed**" system referred to, it should be better **semantics** to call it "**isolated**" system, (i.e. the purely abstract system in which the **2nd. Principle of thermodynamics** strictly reigns).

3/ **- "Macroscopic" and "microscopic"** should be precisely stated in each case.

4/ **- "time-independent"** should not be understood as "outside the **flow** of **time**", which is obvious within the frame of **thermodynamics of irreversible processes**.

D. KATZ and R.L. KAHN state: "Though the tendency towards a steady state is in its simplest form **homeostatic**, as in the preservation of a constant body temperature, the basic principle is *the preservation of the character of the system*. The **equilibrium** which **complex systems** approach is often that of a quasi-**stationary equilibrium**, to use LEWIN's concept (1947). An adjustment in one direction is countered by a movement in the opposite direction and both movements are approximate rather than precise in their compensatory nature. Thus a temporal chart of **activity** will show a series of ups and downs rather than a smooth curve" (1969, p.97).

→ **State (Stationary)**

¹⁾general information

²⁾methodology or model

³⁾epistemology, ontology and semantics

⁴⁾human sciences

⁵⁾discipline oriented

3192

STEADY STATE and ENVIRONMENT^{1) - 4)}

The steady state of a system can be maintained only as much as its **environment** remains mostly **homeostatic**, i.e. characterized by a rate of **change** very inferior to the adaptive capacity of the system. This is consonant with:

- ASHBY's **Law of requisite variety**
- VENDRYES' concept of **counter-aleatory reserves**

Furthermore, the system must be very small in comparison with its **environment**, as its own **transformations** should not disturb it seriously.

An interesting example is the relatively small total mass of the living beings, compared with the total mass of the planet. Thus, these **living systems** are able to maintain their steady state. However, the enormous power of the human mass presently growing on the planet, could possibly alter some aspects of the global steady state of the latter.

In any case, the steady state of a system involves a **set** of permanent imbalances between the system and its **environment**.

3193

STEERING^{1) - 2)}

The guidance of a system.

Steering is a not too clearly understood **cybernetic concept**, even if it corresponds to the very original name of **cybernetics**. (Kybernetes = Helmsman).

In engineering, steering devices are constructed ad hoc. However, many of them must still be piloted.

In **human systems** too (enterprises, **organizations**, nations), in principle, steering implies the presence of a helmsman and some **power device** or **subsystem** to help him in his task.

Steering also implies willful **control** of the system by the helmsman, with the *purposeful* intention to drive it toward some **goal**. It is a "**control for**" case.

There are however some difficult question marks:

- Are systems really **governable**? And, if so, to what extent?
- Why and how does a helmsman reach a power position?
- How does a helmsman acquire the basic **concepts** and **methods** he applies in his steering action?
- Why and how do the power devices become established (or overthrown)?

There are until now no clear answers to these questions and the most recent **changes** in socio-political systems (f. ex. the rise and fall of the so-called Sovietic system), while profusely, *described*, are still widely unexplained in depth.

3194

STEERING (Self-)^{2) - 4)}

The automatic **self guidance** of a system.

If social systems are **autopoietic** and in **dynamic equilibrium**, it could be conjectured that their steering by leaders is, at least in part, an illusion. The leaders who become powerful could merely be those who understand, or even merely perceive, the basic **trends** and needs of the system at some precise moment, and know how to translate them into proposals and projects. On the contrary, the would be leaders who do not interpret correctly the needs of the system, would find themselves blocked by its resistance to the **changes** they propose.

However, if **social systems** are evolutive and **emergent** – as it seems to be the case at some moments in history – then the **random** appearance of some or other leader in such a system in a **far-from-equilibrium situation**, could be determinant for the **emergence** of a more **complex system** at a **bifurcation point**.

The whole subject was treated in "Sociocybernetic paradoxes" – Eds. F. GEYER and J. van der ZOUWEN (1986)

→ **Governability**

3195

STELLAR TYPE SYSTEM^{1) - 2)}

A. MALINOWSKY proposed this concept according to which an **integrated system** maintains a maximum coordination through a central **link**, or **subsystem**, uniting and controlling the whole of the internal **organization** of the system. *Only this* central **subsystem** is tied up in an evolutive way. This means that eventual innovative characteristics within the dependent **subsystems** are allowed only if they do not contradict the **constraints** imposed by the central **subsystem** (See BLAUBERG et al, 1977, p.218)

The apparent contradiction between **autopoiesis** and **evolution** seems thus eliminated. **Evolution** is still possible, but only within the **limits** of the already strictly fixed characteristics resulting of former **evolution**.

By the way, this explains why there is no "way back" in **evolution**: it is never possible to undo what has been done. In **parasitism** for example, even when various functional **subsystems** are eliminated or reduced, the basic nature of the parasite is not altered.

Conversely, a new adaptive device, may very well be quite innovative and solve in a completely unexpected way a seemingly insoluble problem: man has no wings, but he may "fly", for example using a Delta wing.

3196

STEM²⁾

"A line of **communication** in a **hierarchy**".

"Stems connect higher and lower **holons** in **hierarchical structures**". (T.F.H. ALLEN & T.B. STARR, 1982, p.278)

3197

STEP FUNCTION

→ **Function (step)**

3198

STIGMERGY^{1) - 2) - 4) - 5)}

The alternate and reciprocal transfer of structural and/or functional **information** from individuals to the system they are **part** of, or of the system to its **environment**, and conversely.

This notion was introduced by the French entomologist P.P. GRASSÉ (1959), who generalized it from the growing **interactions** he observed between the activities of the members of some insect societies (termites), as a result from the also growing **perception** by individuals of the results of these activities. The stigmergy **process** in these insects includes two phases. The first one is uncoordinated deposition of material on the available surface. However, the termites diffuse a specific scent at the construction places, which acts as an attraction factor where the activity is important. This provokes a more ordered concentration of insects, leading in turn to coordinated construction work.

PRIGOGINE found that stigmergy is a specific case of **order by fluctuations** and emergence of **order parameters** (1976, p.113-4).

Th. SEELEY observes: "The use of the *shared environment* as a **communication** pathway has certain attractions, including easy asynchronous **transfer of information** between individuals and virtually automatic **transfer of information** between any two individuals sharing some portion of the nest..."

"Because the **process of integration** of a **group** is largely a matter of **information flow** from **group** to individuals, it may be that **information flow** through the *shared environment* has been natural **selection's** principal technique of **integration** in building **superorganisms**" (1989, p.550).

Indirect **information** by environmental cues and **coalescence** of collective oriented **behavior** seem to be a most important and quite general motor for **progressive integration**. This **process** is also obviously very common and active in human societies.

While stigmergy is in some sense inheritance of characters through **environment**, it is also clear that there must be a previous state of **coadaptation** between the environment and the individual members or group of members of a species. This is needed in order to trigger the

activity of the individuals. Such activity could lead in some cases to changes in the environment and, eventually, new adaptations in the species.

The monkeys which learned in Japan to clean their tubers in salt water of the seaside, are possibly on their way to stigmergy through shared **behavior**

A process very similar to stigmergy has been described by D. SHÖN (1983, 1987) and J. BAMBERGER and D. SCHÖN (1991) and named by them "**learning as reflective conversation with materials**". In a note to J. Bamberger, D. Schön used the expressions "reference **entity**" and "reference **structure**" and wrote: "a reference entity is situational...and takes something perceived and bounded in that **situation** as entity for use as comparison, projective **model**, prototype within that situation" (J. Bamberger, 2000, p. 15)

He adds however that "it cannot travel from situation to situation" (ibid). Thus an agent-supposedly a living agent- is a necessary go-between.

3199

STIGMERGY (Selective) ²⁾⁴⁾

The progressively limited **selection** among environmental **clues** tending to the most efficient **behavior**.

An example is the finding of food by ants. When different **paths** are possible "the first ants to arrive at a fork choose their way at **random**. They leave **pheromone** trails behind them and newly arriving ants will choose the most "pungent" path, which tends to be the shortest. Longer paths disappear as the pheromone evaporates" (M. WARD, 1998, p.34)

This **reinforcement** based on **selection** through **positive feedback** is obviously a very general **process** that better explains the origins of stigmergy itself. It can be observed in many social **situations** in animal and human societies.

3200

STILL-PICTURE MODEL ²⁾

The model of a system at a given moment.

This expression was proposed by B. BANATHY (1973, p.88).

It is quite useful since this 'snapshot' view is by nature repetitive and helps to visualize the continuously changing character of the system.

Of course, it also helps to understand that such a still-life and **static image** of the system is, if not repetitive, very misleading.

3201

STIMULATION (THRESHOLD of)

→ **Threshold of Stimulation**

3202

STIMULUS ¹⁾

1. "Any physical **energy**... that (a) actually (not potentially) participates in the excitation (or activation) of sensory **receptors**, and, (b) is independent of any activity which the **subject** may engage in" (S. KATZ, 1976, p.42).

2. "Anything that touches off a **receptor** or causes a **response**" (J.J. GIBSON, 1986, p.56).

St. KATZ comments: "... the term **stimulus** is identical to what POWERS calls a **disturbance**" (ibid).

However, the *perceived* stimulus is not anymore only an **event** in the **environment**: it is received and treated in a definite way by an **autopoietic system**.

As to GIBSON, he states "And note above all that an **object** cannot be a stimulus, although current thinking carelessly takes for granted that it is one" (ibid). A **response** is then an **effect** in a perceiving **organism**, i.e. *one that is organized to perceive it*. Observe also that **perception** is not necessarily conscious: a living **organism** perceives ultraviolet light, but is not conscious of it.

Any **organism** need a proper level of stimulation. Insufficient stimuli, as well of excess of them would send the organism out of its limits of **dynamic stability** and could destroy it.

3203

STIMULUS (Discriminative) ²⁾

This notion introduced by W.T. POWERS (his page on the web) seems to imply two different meanings:

1) the stimulus reflects a former behavioral **reinforcement** relative to what it is significant. In turn, it triggers one more reinforcement **event**. For a driver an example would be: "On this corner I must turn right to reach my home" and later on "In effect, after having turned right, I am now reaching my home".

2) the stimulus reflects a number of significant characteristics that help to recognize the corner, as for ex. a one-way traffic sign, a restaurant and a lighting post with the number 23.

The discriminative stimulus is thus related to POWERS' **environment function**.

3204

STIMULUS within CONTEXT ^{1) - 3)}

According to G. BATESON, no stimulus can be significant out of **context**. He correspondingly proposes: "a **hierarchy** of logical types as follows:

- Stimulus is an elementary **signal**, internal or external.
- Context of stimulus is a **metamessage** which classifies the elementary **signal**.
- **Context of context** of stimulus is a **metamessage** which classifies the **metamessage**. And so on" (1973, p.260).

In this case, the concept of **metasystem** is of great significance (J.van GIGCH).

3205

STIMULUS-RESPONSE ²⁾

"A mechanistic **model** involving causal chains." (T.F.H. ALLEN & T.B. STARR, 1982, p.278).

It would possibly be better to write "involving only a single linear causal chain".

3206

STOCHASTIC EFFECTS ^{1) - 2)}

The possible effects that can be produced by **random perturbations** in a system.

These effects can be either insignificant, or very serious, as explained by P.M. ALLEN et al: "Instead of stochastic effects being simply minor irritations for the **modeller**, producing a deviation from the "mean" of his **predictions**, we see that in fact they (may) drive the system from one **state of organization** to another - they are the vital force of **evolutionary change**" (1984, p.248).

The "vital force" of **change** seems in fact to be **energy overload**, while in the **far-from-equilibrium situations** thus produced, a stochastic **event** can act as an **trigger** orienting the **change**.

→ **Nucleation**

3207

STOCHASTIC PROCESS ²⁾

A process that runs through successive **random**, or seemingly **random (chaotic) states**.

Stochastic is, basically, that which cannot be forecasted in a strictly **deterministic** mono-causal way. Examples are epidemics, traffic on crowded roads, stock market **fluctuations**, movements in crowds.

It is "none the less possible to specify both the average (random) interval and the ultimate **pattern** to which those intervals will tend to conform in the long run" (S. BEER, 1967, p.43).

F. HEYLIGHEN states however that, in stochastic processes (e.g. **MARKOV chains**) "... a given **initial state** may have several outcomes with different probabilities" (1990a, p.432)

3208

STOCHASTIC RESONANCE ²⁾

The **amplification** of a specific **signal** through a **random noise**.

This **phenomenon** has been described by the Italian physicists R. BENZI, A. SUTERA and A. VULPIANI (see K.S. BROWN, 1996, p.28-31).

In some cases, the very small impact of the **random noise** on the **signal** that may become significant as a **trigger** for a specific **process**, is sufficient to push the **signal** over the brink of **effectiveness**. This **model** has been used by the Italian physicists as a possible explanation for the periodic ushering of ice ages. Other examples are also known. A similar **effect** could explain the sudden magnification from quite

small transactions in the stock market into a generalized panic. In all these cases, of course, the affected system must be close to some **instability threshold**. Still another hypothetical possible case would be a massive change in the oceanic waters circulation **patterns**, for example as a result of partial desalinization of superficial waters by a massive flow of non-salted water due to partial or total deglaciation of the poles.

As stated by R. VALLÉE, **noise** can be an excellent **structure** displayer, even at macroscopic level (1990, p.55).

Stochastic resonance could conceivably be used to produce some **trigger effects**, or explain some whose direct cause is not clear. For more, see P. Mc CLINTOCK and D. E. LUCHINSKY (1999, p.37-39)

→ **Order from noise**

3209

STORAGE¹⁾

The **process** by which the system accumulates **reserves** of **matter**, **energy** and/or **information** and becomes able to delay and select its **responses** to **stimuli**.

P. VENDRYES explained the importance of storing **reserves** for the **operation** and the **maintenance** of **dynamic stability** in systems in general (1942).

He took his insight from the example of physiological **reserves** of the living being, as for example glycogen or fats, which allow for the intervention of functional **regulations** and the **maintenance** of biological **functions** within satisfying **limits** of **oscillations**, in front of the variations of the **flows** incoming from the **environment**.

It is, in fact, that capacity to store **reserves** which allows **organisms** to acquire their **autonomy** in relation to this **environment**, to organize their own internal milieu (or "**environment**") and to maintain what Claude BERNARD named "the constants of the internal milieu", also studied later on (1932) by Walter CANNON under the name of **homeostasis** (1963).

The fundamental potentiality of the stored **reserves** is that they are counter-**random**.

VENDRYES extended in his last works these views to historical, social and economic (including firms) systems (1981).

No system could do for long without such **reserves**, which are needed to counteract **perturbations** from the **environment**.

However, the storage **process** is not free. Stores are **structures** that must be constructed and maintained. For example, H.T. ODUM writes, referring himself to the storage of **energy**: "... such work requires a dispersal of some potential **energy** into heat... If the storing is done at the maximum possible **rate**, then 50 percent must be delivered into the heat **sink**" (1971, p.38-39).

3210

STORAGE CAPACITY^{1) - 2)}

Different types of systems have different storage capacities. According to H.T. ODUM, storage capacity depends in biological and ecological systems of "...the volume to surface ratio, which varies according to the **size** of the storage unit, being large in elephants and small in bacteria" (1971, p.256).

Furthermore, storage becomes more differentiated with **complexity**. **Social systems** have thus an extreme **variety** of storage devices, which correspond to the necessity of disposing at any moment of sufficient counteraleatory **reserves**.

3211

STORAGE (Matter-Energy)^{1) - 2)}

"The **subsystem** which places **matter** or **energy** at some **location** in the system, retains it over **time**, and retrieves it".

This is one of the 20 **critical subsystems** in J.G. MILLER's **taxonomy** of **living systems** (1978, p.3). Obviously this term is a generic one which covers a **variety** of different specialized storage **subsystems**.

3212

STORE¹⁾

1. A supply of some **resource** put in stock somewhere in a system for future use.
2. A specific **subsystem** where such a **resource** is stocked.

The existence of unused **resources** is a guarantee of **survival** for the system if it should be cut off from some necessary **inputs**.

For P. VENDRYES, the existence of such **reserves** is an absolute condition for the **autonomy** of the system (1942, 1981).

3213

STORY TELLING^{1) - 3)}

The use of stories to emphasize some critical and sometimes unheeded aspect of a **situation**, especially in **complex systems**.

This technique has been widely used by R. L. ACKOFF, and sometimes produces striking results. Stories help to discover original angles and new **meanings**, get out of the rut by avoiding commonplace views and stuffy overbearing prejudices, produce **synergies**, increase **competence** in participants and generally stimulate creative insights.

According to R. SCHANK, storytelling is also and **endogenous mnemonic process** of **stabilization** of recollections: "It is the **process** itself of creation of the story which creates the mnemonic **structure** that will contain the basics of this story for the rest of our life" (1995, p.154).

In both cases, the story can be a fabrication, but it is then a meaningful one. A related subject is the construction of **scenarios** for **forecasting** and **planning purposes**.

R. NUMMELA CAINE and M. CAINE observe: "Stories are powerful because they bind **information** and **understanding** over **time**. In fact, there is strong reason to believe that **organization of information** in story form is a natural **brain process**... At a minimum, a story is a sequence of experiences with a meaningful theme" (1994, p.121-2)

Indeed, story telling is as old as Gilgamesh, Ramayana, or Ulysses epopeas and the Bible itself: **values**, **norms** and **understanding** transmitted through an easily assimilated mental fare.

In a somewhat different sense, story telling is unavoidable, even as a contribution to scientific **knowledge**.

C. SLUZKI speaks of the "**EIGEN-values** of stories" (1995, p. 41) Of course, even if very imaginative or even fanciful, no story can make any sense if not connected to what SLUZKI call a "system of **narratives**". Moreover, different **cultures** can offer widely different systems of narratives, each within its own "whole conversing system" (id. p. 45)

S.J. GOULD observes (in "Wonderful Life", as quoted by P. BAK (1996, p.7): "Many large **domains** of nature - cosmology, geology and **evolution** among them - must be studied with the tools of **history**. The appropriate **methods** focus on narrative, not experiment as usually conceived".

This is so because, in these **domains**, no **event** is ever exactly repeated and no reproducible **experiment** can be organized that could eliminate all **contingencies**.

Of course, the **analogies** discovered among different, but more or less similar **events**, as for example a number of earthquakes or various hurricanes, can produce a deeper **understanding** of a whole **class** of **phenomena** and decrease the arbitrary perceptive deformations and interpretations always possible in story telling.

A good example is the discovery of the so-called laws of **chaos**, initially derived from meteorology research by E. LORENZ.

3214

STRAIN^{1) - 4)}

The **state** of a system submitted to **stress**.

Strain can be sustained merely up to some specific **limits**. For instance, **stress** applied by stretching a metal bar, may, according to the force applied:

- when slight, have no visible effects;
- when stronger, induce a permanent deformation;
- when very strong, make it suddenly snap. ("The last straw that broke the camel's back").

Analogically, **living systems** and **organizations**, when submitted to **stress** and suffering strain, may react in the same ways.

It could be said that **constraints** are permanent strains to which a specific system has adapted permanently.

3215

STRATEGIC PLANNING IN ORGANIZATIONS⁴⁾⁵⁾

R. ACKOFF writes: "Strategic planning (selection of ends) tends to flow from the **topdown**, and tactical planning (selection of means) tends to flow from the **bottom up**"

"...it seems to me that strategy can be characterized, if not defined, as follows:

"1. An organization's strategy consists of those **decisions** that are made by its highest **level of management** and that affect the organization as a **whole**

"...**decisions** not made at the top or that do not affect the whole organization are tactical. It follows, then, that a decision that is strategic from an organizational **component's** point of view will be tactical from the organization's point of view. Therefore "strategy" and "tactics" are relative concepts depending on the organizational **level** at which the defining is done.

"2. Strategic decisions set **objectives** for the organization as a whole, relatively long-range objectives, and formulate policies and principles intended to govern **selection** of means by which the **objectives** specified are to be pursued and...

"The focus of tactical decisions is **efficiency**"...while "the focus of strategic decisions is **growth**" (1990, p. 523)

It seems that also in some cases the fight for **long term** (and even **short-term**!) **survival** is a matter of strategy

"3. Strategic decisions focus on prior (**anticipatory**) and posterior (after-the-fact) responses to such potential and actual **changes** in an organization's **environment** as can affect its **performance** significantly and...

"Finally, I think it essential that strategic decisions be so formulated that their implementation and expected **effects** can be monitored

"This requires that their expected effects be stated in observable terms and that they be accompanied by a specification of the times by which the effects are expected" (p.524)

3216

STRATEGY¹⁾

"A preprogrammed behavioral policy" (R. DAWKINS, 1978, p.74).

Such a **program** normally covers **long term planning**.

Tactics are, or should be, subservient to strategy.

According to R. ACKOFF, who reproduces an older definition by himself (1974): "**Strategy** is concerned with long-range **objectives** and ways of pursuing them that affect the system as a **whole**, **tactics** are concerned with shorter-run **goals** and **means** to reaching them that generally affect only a part of the **organization**" (1990, p.523)

While "the focus of tactical **decisions** is **efficiency** the focus of strategic **decisions** is **growth**".

Strategic **decisions** are at times still more fundamental, as they may have to see with the very **survival** of the **organization**.

ACKOFF further distinguishes normative **decisions** "which have an infinite perspective because they focus on ideals, ends that can never be obtained but that can be approached without **limit**. The focus of normative **decisions** is **effectiveness** (which, in contrast to **efficiency**, is a **value-loaded concept**) and **development** (which in contrast to **growth**, has nothing to do with **size** or number, but with an increase in one's ability and desire to satisfy one's own **needs** and desires and those of others" (Ibid).

E. MORIN observes that any strategy should include the consciousness of **uncertainty** in general (1999a, p. 66). Any strategy operates through a program: "The **program** is efficient within stable external conditions, that can be established in a secure manner. However the least **perturbation** of these conditions destabilizes the program's execution and tends to block it" (p. 66)

Finally, we must always navigate in "an ocean of **uncertainty** with some archipels of certainty" (1999b, p. 17)

If there is no **awareness** of any uncertainty, then the strategy and the program are mere bets based on unsustained beliefs and can easily lead to disaster.

Of course, strategy is the activity of a strategist, i.e. a leader who, in a more or less hierarchical and even autocratic way, decides about the future course of the system.

In a sense, this reflects a deeply ingrained **deterministic model** and is antagonistic to the concept of **self-organized behavior** for the system.

The possibility to reconcile both **models** and how eventually to do it, remain two open questions.

Strategies should also care for global **transformations**, with special care for the proper and permanent harmonization of the various **processes** and **functions**, in order to guarantee not only **long-term efficiency**, but also **resilience** and **survival conditions**.

These aspects must be paramount in the definition of pursued **goals**. Most man-made **messes** result from ignoring such traps.

3217

STRATEGY and TACTICS¹⁾

The American Heritage Dictionary defines tactics as: "The technique or science of securing the **objectives** defined by strategy".

Strategy covers **long-term planning** and thus embeds tactics. Furthermore, various tactics are generally possible in order to reach strategic **objectives**.

From a most embracing viewpoint strategy, as well as tactics, depends on the best possible **knowledge** of the considered system, which introduces at least two different, but related, problems:

- the evolving global conditions of the system are rarely known with a sufficient precision, which leaves many times strategy in doubt, or conditional to a subsequent betterment of our **knowledge**.
- In complex systems, **chaotic transformations** reflect this insufficient **knowledge** and may introduce difficulties even at the tactical **level**.

However the general **embedment** of **short-term trends** within **long-term** ones may be of some help.

3218

STRATEGY (Evolutionarily stable)^{1) - 2)}

A strategy which, if most members of a **population** adopt it, cannot be bettered by an alternative strategy" (R. DAWKINS, 1978, p.74)

According to DAWKINS, this concept was introduced by J. MAYNARD SMITH.

DAWKINS explains it as follows: "... the best strategy for an individual depends on what the majority of the **population** are doing. Since the rest of the **population** consists of individuals, each one trying to maximize his *own* success, the only strategy that persists will be one which, once evolved, cannot be bettered by any deviant individual" (Ibid).

This is totally valid only in stable **situations**, as recognized by DAWKINS: "Following a major **environmental change** there may be a brief period of evolutionary **instability**, perhaps even **oscillation** in the **population**" (Ibid).

It should be observed that to speak of the evolutionary strategy of a **population** is somewhat semantically abusive. The individuals are more or less collectively subservient each one to all the others, in a statistical way: the global so-called strategy cannot be assigned to any specific entity; it remains diffuse within the **population**, and may be represented by a **transitions probability matrix**.

3219

STRATUM²⁾

"The **level of description** or **abstraction**" (M. MESAROVIC's et al **taxonomy of types of hierarchical levels**, 1970, p.37)

¹⁾general information ²⁾methodology or model ³⁾epistemology, ontology and semantics ⁴⁾human sciences ⁵⁾discipline oriented

A stratum is a horizontal **layer** in a **hierarchy**.

3220

STRESS ¹⁾ - 4) - 5)

1. An internal tension induced in a system by unfavorable external factors, impacts of **situations**.

Materials can be stressed, for example by excessive weight, compression, pulling or stretching. The result is **strain**, and sometimes **breakdown**.

The concept has been extended to physiology (see hereafter), and in a somewhat metaphorical way, to psychology and social psychology.

2. The **state** corresponding to all non-specific **responses** of the body to any demand.

(This definition is a synthesis of various more or less equivalent ones given by H. SELYE, who introduced the concept) (1975).

"Any demand" is practically anything that affects the system's **homeostasis**, which means quite normal activities as well as aggressions coming either from the **environment** or from the **invironment**.

SELYE states some interesting points:

"- The stress **response** is, by definition, not specific, since it can be produced by virtually any **agent**.
